OBSERVATIONS ON LATERAL CURVATURE OF THE SPINE;
PATHOLOGICAL, CLINICAL, MECHANICAL.*

By A. M. PHELPS, M. D.,
NEW YORK.

LATERAL curvature of the spine rises before us each year like a spectre. From every clinic in every country the orthopædic surgeon is deluging societies and medical journals with literature upon the subject. It is interesting to note that, from the earliest records we can find upon the subject down to the present time, the positive position taken by the author is only to be retreated from a year or two later. Then, again, we find in each quarter or half of a century the revival of ideas of the past, which ideas at the time they were published were considered absolutely correct, but after a very short time were relegated to the obscurity which they so justly deserved; only to be revived again by some enthusiastic orthopædic surgeon. Nearly all of the mechanical work, and part of the mechanical methods of support and gymnastics, advocated in this association at the present time are only revivals of ideas which have run the gauntlet in centuries past. They have been tried, found wanting, and discredited, only to be revived again in a later century. I have visited the principal clinics of Europe and this country. I have spent a great deal of time with the various authors. I have found that they all agree and all differ. They all say that they cure these cases, but, upon close investigation, I have yet to see the first case of lateral curvature of the spine, in which bone change had taken place, cured by any plan of treatment known to the scientific world. In these observations I find opinions varying all the way from those who advocate nothing but gymnastics; those who believe in gymnastics and mechanical treatment, to those who believe in mechanical treatment alone. All report equally good results, but I note in most of the writings that the following statement is to be found: "The results were entirely satisfactory." I have often asked myself the question: "To whom?"

Now, here we stand with this problem confronting us—unsolved, treated in an empiric manner, running the same gauntlet of discussion and dispute as did congenital dislocation of the hip and causes of deformity in hip-joint disease.

It is this panorama which has appeared before us that has led me to present to you to-day the result of my observations in this peculiarly obscure deformity. Its cause is obscure, its pathology has been even more so, and its treatment in many instances even worse. I had firmly come to the conclusion that if we ever expected to arrive at a conclusion as regarded the ætiology, pathology, and treatment of lateral curvature of the spine it had to

be done with the scalpel. I am frank to state to you that the work which I have done with my assistants in the past two years has amounted to but very little; still, it is something. It is along the lines which should be followed, in my opinion, and which will eventually lead to a solution of this problem.

It is extremely difficult to get subjects of lateral curvature of the spine for dissection, and until a great number have been dissected whose history is well known we

FIG. 1.

shall never advance in our work in lateral curvature of the spine.

I desire to-day to give you the work which, with the assistance of my staff at the Post-graduate Medical School and Hospital, we have performed. It is simply preliminary, and should be received for what it is worth, and no more.

Two years ago I secured a specimen of a severe form of lateral curvature of the spine from a patient who died in the workhouse from natural causes. He had been there for many years, and no one could ascertain what caused his deformity. It had been with him as long as he could remember. A few years before he died he was afflicted with chronic rheumatism which resulted in contraction of one of his limbs, but there was no considerable joint disease. This case was taken to the dissecting-room of the

* Read before the American Orthopædic Association, May 1, 2, and 3, 1900.

Post-Graduate, and there, with the assistance of Dr. Hendle, I dissected out the muscles of the back.

We found that the superficial layer of muscles, particularly the latissimus dorsi, trapezius, and the superficial layer of the erector spinæ muscles were in fairly good condition upon the side of concavity, but upon the side of convexity there was not only atrophy but marked degeneration of the muscle. Fig. 1 shows these muscles, and gives a very correct idea of what we found. The superficial group of erector spinæ muscles upon the side of convexity was entirely destroyed by atrophy and fatty degeneration, while those upon the side of concavity were

were found. The intercostal muscles on the side of concavity had also undergone fatty degeneration where the ribs were still apart, but on that side the ribs had approximated and even overlapped, destroying entirely the intercostal muscles, binding the ribs together with firm fibrous material—remains of the intercostal muscles. On the side of convexity, however, the intercostal muscles were found to be also degenerated from pressure on account of the ribs being widely separated. This constant pulling upon the intercostal muscles made pressure upon the muscle cells by the approximation of the myolemma, and resulted in atrophy almost if not complete destruc-

FIG. 2.

FIG. 3.

not so much affected. These muscles were dissected away, exposing what remained of the deeper layer of muscle. We found that the quadratus lumborum and the erector spinæ group of muscles of the deeper layers were entirely destroyed by fatty degeneration and atrophy on the side of convexity. On the side of concavity the quadratus lumborum and the erector spinæ muscles, although somewhat degenerated, were not so far advanced as upon the side of convexity. This condition of the deeper layer of muscles was found all along the back to the seventh cervical vertebra—throughout the region of the spine affected by the double curves. Fig. 2 shows a dissection of what was left of the deeper layer of muscles. Nothing but aponeuroses and a few muscle fibres

were found. The intervertebral cartilages upon the side of the convexity were entirely obliterated, the bodies of the vertebrae coming in contact one with the other. The transverse and articular processes were warped and twisted, the ligamentous connection between them being so shortened that dissection of them was practically impossible. Upon the convex side, however, the intervertebral cartilage was not totally destroyed. The transverse processes were widely separated and the articular facets on that side were slipped one by the other to a limited extent. The bodies of the vertebrae at the point of greatest curve upon the concave side were absorbed to one half, and in some instances to the entire thickness of the vertebra. The pressure at these points had been so great that new

bone had been thrown out to prevent further bending and absorption of the vertebræ. The muscles, or what was left of them, on the concave side of both curves were so shortened that it was an impossibility, with any force that we could apply, to make any perceptible effect upon the curves. It was not until after these fibrous bands, the remains of the muscles, were divided that any effect could be exerted. The thorax had already upon the right side (side of cavity) pressed upon the crest of the ilium as is seen in Fig. 3, bending the ribs upward, forcing

convex curve of the vertebræ, as is seen in Fig. 5. The vertebra at each curve was rotated upon itself until the transverse processes pointed directly back, as is seen in Fig. 6, taking the normal position of the spinous processes. The bodies of the vertebræ and the spinous processes pointed transversely instead of anteroposteriorly.

Now, the conclusion at which we arrived from this specimen was this:

There had been no evidences of paralysis or brain disease in the case. Therefore, that factor was left out of

FIG. 4.

FIG. 5.

them together, lapping one upon the other. The efforts at respiration to increase the capacity of the thoracic cavity had resulted in the bending of the ribs upward anteriorly, which gave space between them in front. Notwithstanding, on the concave side they were tied firmly together and overlapping, while upon the convex side they were widely separated, as is seen in Fig. 4. A side view, however, of the thorax shows the arching upward and bending downward of the lower ribs, produced by pressure upon the crest of the ilium (Figs. 5 and 6). The widely separated condition of these ribs is due to the

the question. We found that the superficial group of muscles had acted upon the shoulders and trunk and moved the entire trunk *en masse*. The fatty degeneration and atrophy on the convex side were due to the pressure of the muscles by the bending of the bones of the spinal column, putting these groups of muscles on the stretch, whereas the degeneration and atrophy on the concave side were produced by the contraction of these muscles and their long disuse.

The entire trunk had telescoped together until the ribs rested upon the pelvis, which prevented any normal

motion of the vertebral column. The bending of the ribs, their overlapping and firmly binding together by the fibrous remains of the intercostal muscles upon the concave side; the atrophy and degeneration of the intercostal muscles upon the convex side between the widely separated ribs, resulting in atrophy, told us that it would be an impossibility to remedy this deformity without first widely separating the ribs upon the concave side, which might allow the curve to be straightened, provided the deformed vertebrae did not prevent.

Assuming the fact that the thorax was not deformed in any way; that the ribs upon the concave side were not

FIG. 6.

firmly bound together, and overlapping, by contracted intercostal muscles which had undergone degeneration, leaving only fibrous tissue, it would then be an impossibility to straighten the curve in any way on account of the destructive changes which had taken place in the vertebrae and intervertebral cartilages, changing the plans of the articular surface of the bodies of the vertebrae. No matter how slight, how little the change in the bones which had disturbed the equilibrium of the spinal column, thereby allowing the approximation of the ribs and shortening of the intercostal muscles upon that side, it would be an impossibility to straighten that curve until

every rib had been detached from the other, and even then the spinal column would not stay in the perpendicular position, owing to the fact that the plane of the articular surfaces of the bodies of the vertebrae had been changed to an angle.

It was also observed that in proportion to the amount of curvature we found rotation, and that rotation took place in the direction of the curve, and in the lower curve that rotation had taken place until the vertebrae lay transversely to the body. The vertebrae being in this position, had undergone change by absorption until they were wedge-shaped and warped. No force on earth short of fracturing the spinal column could have in any way changed the position. Now, when lateral curvature of the spine, which is always accompanied by rotation, begins in the dorsal region, a corresponding change takes place in the shape of the ribs. When the change has once taken place, and bone has been destroyed by absorption, producing the curve, no means of which we know could in any way effect a restoration of the parts. It is a mechanical impossibility short of killing the patient.

These are the propositions and conclusions at which we arrived. We know perfectly well that in genu valgum associated with shortening of the external condyle, no bracing, however skilfully applied, can ever remedy that deformity. We also know that after the bones have once become thoroughly consolidated no amount of skilful bracing will cure the bow-leg. While this may be possible during the time that the bones are soft, after they have become once thoroughly consolidated it is a practical impossibility. These facts have led the profession to adopt osteotomy and osteoclasis in remedying these deformities.

We have in the spinal column a complicated column. Instead of a straight shaft of bone, like the femur articulating with its tibia, we have here a combination of bones articulating closely posteriorly and laterally, and then attached to these bones are the ribs, the levers running out on either side from the upper to the lower dorsal vertebrae. The spinal column bends, producing destruction of bone and intervertebral cartilage, and by pressure the ribs are distorted and overlapping, and the muscular elements between the ribs become changed by shortening, atrophy, and degeneration. So, how futile it must be to hope to cure a lateral curve of the spinal column! Not only do we find the resistance offered by the wedge-shaped bones of the vertebral column, but these distorted ribs must be rotated in order to cure the curve.

I leave this problem at this point, and hope at some future date to go on with the work in other cases. Now, the conclusions at which we arrived from these dissections correspond very closely to the clinical observations which we made.

As I remarked at the beginning, I never saw a lateral curve and rotation due to destruction of bone from pressure, with corresponding deformity of rib, removed from the spinal column by any method.

My observations have been made in my own clinic and private practice, and also in the various clinics of this country and Europe; and they are, that the most that we can hope for at the present time from treatment is to prevent (and that is not always possible) the increase of the curve, to remedy the physiological curve, and to give our patients, if possible, strength.

I visited Bernard Roth and spent some time with him in his work. I saw no different results in his work from what I saw in the work of many gentlemen in Europe and this country who advocate that nothing but gymnastics be used in these cases. None of his patients recovered. They grew stronger physically, but the curve remained. In the institution of Schilbaak, at Leipsic, where all sorts of gymnastics are used, and patients are placed in bed for hours each day after the gymnastic work, upon specially constructed beds, none are cured. In this country the gentlemen who have accepted the idea that gymnastics is all that is required in such cases tell me they do not cure their cases, that the most they can hope for is to give their patients strength and arrest the deformity and possibly improve the physiological curve. From the hands of some of these gentlemen many of their cases drift to my office and into my clinic. I find that those who come to me give the history of increased deformity. This leads me to believe that gymnastic treatment alone is one of the greatest fallacies that have ever been taught. So long as the patient is in the upright position the weight falls on the curves and produces further absorption of bone and distortion of the thorax. It is advocated by these gentlemen that gymnastics will strengthen the muscles and hold the spine erect. From this statement I must dissent, because the muscles do not hold the spine erect. The spine is held in the upright position on account of its anatomical construction and ligaments—the muscles balance. Muscles could not stand the strain of holding the spine in the upright position. If the arm is held at a right angle to the body it soon tires and cannot be retained in that position. The muscles of the arm are not different from those connected with the spinal column. Therefore, the idea that the training of muscles will straighten these subjects is erroneous and not proved; it does not even prevent them from growing worse if the deviation from the median line has amounted to more than one half the diameter of the vertebra. All that can be accomplished by gymnastics is upon the constitution of the patient.

Now, in regard to the various machines that have been devised in the past three hundred years, revived from time to time and presented to the profession, I can only say of them as I say of gymnastics: They can have no possible effect upon the curves and the rotations *per se*. The only possible good they can do is to assist in holding up the spine, but so long as the ribs are bound together by contracted intercostal muscles that force can be of but little avail. However, under an anæsthetic, force applied so strongly as to fall short of breaking the

ribs might be of some use, provided the vertebral column was held in the corrected position after the force was applied.

This leads me to the consideration of the proper mechanical treatment of lateral curvature of the spine; and, believe me, gentlemen, it is all, or nearly so, a question of mechanics. Under an anæsthetic great force can be applied, so great that the patient could not possibly endure it without. While the patient is under the anæsthetic this tremendous force can be applied to the thorax and spine, either by machinery or by half a dozen hands, and any muscles or fascia which offer resistance can, under these circumstances, be divided with a knife. In this manner I have succeeded in taking a great portion of the curve out of the spinal column; but even with all this, I have never yet succeeded in straightening a curve in which bone change had taken place. After the operation the patients are enveloped in plaster of Paris, put to bed, and kept there for two or three weeks, after which the operation is repeated. This, it seems to me, is the only operation to be advocated in lateral curvature of the spine.

The specimens which I have dissected seem to demonstrate this, and clinical observation verifies it without a doubt. Then comes the question, What is to be done after the curve has been remedied so far as possible by great force under an anæsthetic and the muscles have been divided with the knife? When the patient is convalescing, there is no question in my mind but that the suspension of that patient and the application of a proper support should be the law. Inasmuch as the force of a support must exercise pressure varying from twenty-five to one hundred pounds, depending upon the size of the patient, it would stand to reason that the support which made pressure on the greatest possible surface of the body would be the one to choose. Steel braces could not be borne under these circumstances, and, in my opinion, should not be used. Therefore, any support which has for its object an anteroposterior action is scientifically wrong in any lateral condition, whether in lateral curvature or Pott's disease.

The mechanical support for lateral curvature of the spine should be as rigid as an oak, because it is dealing with a rigid spine. It should be light. It should be porous. It should be durable. The plaster-of-Paris corset comes the nearest to these requirements of any of the cheap dressings. Poroplastic felt, leather, raw hide, and paper do not fill these requirements, because they will change their shape under pressure and moisture. They should never be used for spinal supports. I have tried them all, and I know whereof I speak. I have seen patients shortening in the summer time in a single week. Celluloid is worse, because it will not hold its shape for forty-eight hours; and the wood corset is absolutely worthless. I advise the aluminum corset, which, to my mind, is the most perfect support ever devised. The patient can go in bathing without taking off the support.

Now, in regard to gymnastics. To change the form of the thorax, which will aid materially in somewhat alleviating the curves, breathing exercises which expand the chest, elevating the ribs, which applies a force direct to the spinal column, assist materially. Exercises should be performed while the corset is on. It is wrong to take it off. The physiological curve can be overcome only by constant support and muscular development, and the pathological lateral curve by preventing the patient from assuming the erect position without his corset. Light gymnastics are far preferable to heavy. Heavy gymnastics develop muscle, but no quicker or surer than light gymnastics. We can learn a very important lesson from the sporting world, where heavy gymnastics have been entirely discarded. Muscles developed by heavy gymnastics undergo rapid degeneration when the gymnastics are stopped.

I am sorry that this paper is incomplete. It has told but little. It has told something. It is the beginning of a work which I hope others will assist in. I have no doubt that if these lines are followed out for the next twenty-five years the problem of lateral curvature will be solved.

I offer the aluminum corset, Fig. 7, as a substitute

FIG. 7.

for many of the braces and corsets now worn in the acute forms of Pott's disease and lateral curvature; I suggest it to take the place of such braces in cases requiring permanent bracing, or in individuals who are desirous of securing a support at any time which combines durability with lightness and comfort. So soon as a case of lateral curvature has been arrested, or the greatest amount of benefit has been derived from treatment, the aluminum corset will be found a most agreeable, permanent support. The aluminum corset has these qualities to recommend it to the patient:

1. Lightness.
2. Durability.
3. It is thin and does not interfere with the form and clothing.
4. Being extensively perforated makes it the coolest and most agreeable of supports.

5. The patient can wear it during bathing.

An ordinary corset weighs from one to two pounds, depending upon the size. To prevent cracking and to protect it from perspiration, it is covered with a water-proof enamel, which is applied by heat.

The steps of its construction: Make a plaster form of the body; send this form to the foundry and have a cast-iron anvil made; polish this, and then at a certain temperature the workmen will bend on to it two sheets of aluminum representing the two lateral halves. The frequent heating and hammering, together with the cylindrical shape, make the corset almost as strong as steel. The two halves are hinged in the back and closed with automatic clasps in front, which stop at any notch to accommodate the corset to the body before and after eating. This corset completes my armamentarium in cases requiring spinal supports, viz.:

1. Plaster-of-Paris corsets for acute Pott's disease.
2. The Hessian corset for mild forms of lateral curvature, particularly in girls.
3. The aluminum corset for permanent bracing.

The wood, celluloid, paper, wire, leather, and felt corsets are worthless. They change in shape and do not support the spine.

THE MESIAL RELATIONS OF THE INFLECTED FISSURE; OBSERVATIONS UPON ONE HUNDRED BRAINS.

BY EDWARD A. SPITZKA,
NEW YORK,

STUDENT OF MEDICINE, COLLEGE OF PHYSICIANS AND SURGEONS.

SEVERAL cerebral morphologists have paid special attention to the so-called inflected fissure. Lussana, of Padua, first named it *solco inflesso*, while in America it was first noted by Professor Wilder (1), in 1885. The latter says of this fissure that it "indents the dorsi-mesal margin just cephalad of the precentral fissure, and paracentral lobule. In the brain exhibited (from an adult mulatto) it is particularly distinct, and is shown in the outline figure in the *New York Medical Journal*, February 23, 1884 (Fig. 42). It seems to have been described by Lussana and Lemoigne (*Fisiologia dei centri nervosi encefalici*, Padova, 1871) under the name of *solco inflesso*; paronymized, in Latin this becomes *fissura inflecta*, and in English the *inflected fissure*."^{*}

More recently, Eberstaller (2), in his work, *Das Stirnhirn*, gives to this fissure the long name *sulcus prae-centralis medialis*, which Wilder (3) considers a "needless and unwarranted change of names," an opinion with which critical students will agree. However, Eberstaller

^{*}Through the kindness of Professor Wilder, I have been enabled to examine the copy of Lussana's *Fisiologia*, belonging to the library of Cornell University. The fissure in question is designated *Solco inflesso* in Fig. 177, and *Scissura inflessa* in Fig. 179, substantially as in Fig. 1 of this article. It is not described by name in the text, and only a brief allusion to it is made on page 163. I take this opportunity to express my thanks to Professor Wilder for this and other favors.

commits another error, more grave perhaps than the one Professor Wilder has unearthed, inasmuch as it has misled many writers and perpetrated a misinterpretation which has existed in our literature to the present day. His error consists in the identification of Lussana's (4) and Wilder's inflected (or Eberstaller's *sulcus praecentralis medialis*) with the fissure named by Broca *incisure pré-ovale*, and by Schwalbe *sulcus paracentralis*.

On referring to the writings of Broca and Schwalbe, it becomes evident that the pre-oval incisure and paracentral sulcus of these two writers do not correspond with the so-called inflected, but that both designations refer to the cephalic limb of Wilder's paracentral, a ramus for which Eberstaller himself suggests the name *preparacentral*. Broca (5) describes it as an "*incisure pré-ovale de la scissure sous-frontale*," and the wood-cut illustration which accompanies his article renders his meaning absolutely clear. Schwalbe (6) likewise represents this as a ramus of the calloso-marginal in Fig. 339 of his *Lehrbuch*, and beside the clear and accurate description of his *sulcus paracentralis* as a cephalic limiting ramus (on page 541) he expressly identifies this fissure with Broca's *incisure pré-ovale* (in a footnote, page 544). The various synonyms for this ramus may therefore be properly grouped as follows:

<i>Incisure pré-ovale.</i>	Broca.
<i>Sulcus paracentralis.</i>	Schwalbe.
<i>Sulcus praeparacentralis.</i>	Eberstaller.
<i>Cephalic paracentral limb.</i>	Wilder.

In only nine per cent. of the brains examined by me did I find this limb separated from the paracentral and usually it was confluent with the *supercallosal* (Fig. 2). In the event of separation the interposed isthmus was in-

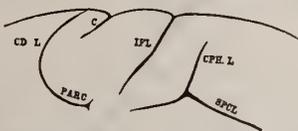

FIG. 2.—The cephalic limb is separated (in 9 per cent.) from the paracentral, generally by a narrow isthmus; when so separated this limb was commonly confluent with the supercentral.

variably very narrow and insignificant and in no case did I observe that this cephalic ramus ever crossed the dorsomesal margin. On the other hand, the true inflected fissure always cuts across the margin to appear on both meson and dorsum, and only in rare instances, contrary to Eberstaller, is it confluent with the paracentral (or "calloso-marginal"). On this point Eberstaller seems to contradict himself, for, after stating that the *sulcus praecentralis medialis* is situated caudad—by the breadth of one gyrus—of his "*Anfangsstück der Pars posterior*" of the "subfrontal," he thereupon says that these two fissures anastomose in fifty-five per cent. of his cases. What error of observation or interpretation underlies the latter statement I cannot say. However that may be, his comments upon Schwalbe's description are based upon a gross misinterpretation, as inconsistent as it is erroneous.

We are dealing, then, with two distinct fissures which have been erroneously identified with each other ever since Eberstaller's work gained its wide circulation. The inflected fissure was probably unknown to Schwalbe under any name whatsoever, and it is unrepresented upon Ecker's diagrams (7). The contributions of Lussana and Wilder have already been mentioned. Flesch (8) in 1885 designated it as the *x-fissure*, and, with Familiant (9), believed it homologous with the *cruciate fissure* of the carnivores. Benedikt's view (10) is that the cruciate fissure is represented in man by both of the fissures discussed in this paper, at least so they are described: (1) on the meson, the anterior limiting fissure of the paracentral lobule; (2) on the dorsum, a transverse fissure which limits the superior part of the precentral gyrus. As Wilder (3) pointed out, one is left "in doubt as to whether the lateral fragment is the inflected fissure or the supercentral or some third fissure."

In opposition to these opinions, Betz is said (11) to favor Broca's *pre-oval incisure* with this claim.

Having shown, then, the importance of distinguishing between these fissures from a physiological as well as morphological standpoint, it will become apparent that the anatomical relations of these fissures are of equal importance, and with this view I carried on the researches* which form the basis of this paper, in the anatomical laboratory of the Columbia College of Physicians and Surgeons. I am indebted to Professor Huntington and Dr. B. B. Gallaudet for their courteous permission to examine one hundred brains of dissecting-room subjects. The brains were hardened in formalin and were in a good state of preservation.

Among the various fissural schemas with which I am acquainted, Professor Wilder's (12) is the *only one which places the inflected cephalad of the cephalic paracentral limb*. Wilder's figure was based upon the brain of the mulatto described by him in the Handbook article and in the *New York Medical Journal*, February 23, 1884. That this extraparacentral position of the inflected is an anomalous and rare one will be seen in the latter part of this paper.

The results obtained by my investigations present many interesting features, but only a brief résumé can be given in these columns.

It was found that in 40 hemispheres of the 200 examined, the inflected fissure was wanting; in other words, it was present in eighty per cent. Its absence was symmetrical (*i. e.*, on both halves) in 6 brains, or three per cent., while it occurred 22 times on the left and 18 times on the right half.

All further data are based upon the 160 hemispheres in which the fissure was present, as equivalent to 100.

In ninety-one per cent. the inflected was situated in a

*It is intended to present a detailed account of these investigations, with numerous illustrations, at the fourteenth session of the Association of American Anatomists, held in Baltimore in December, 1900.

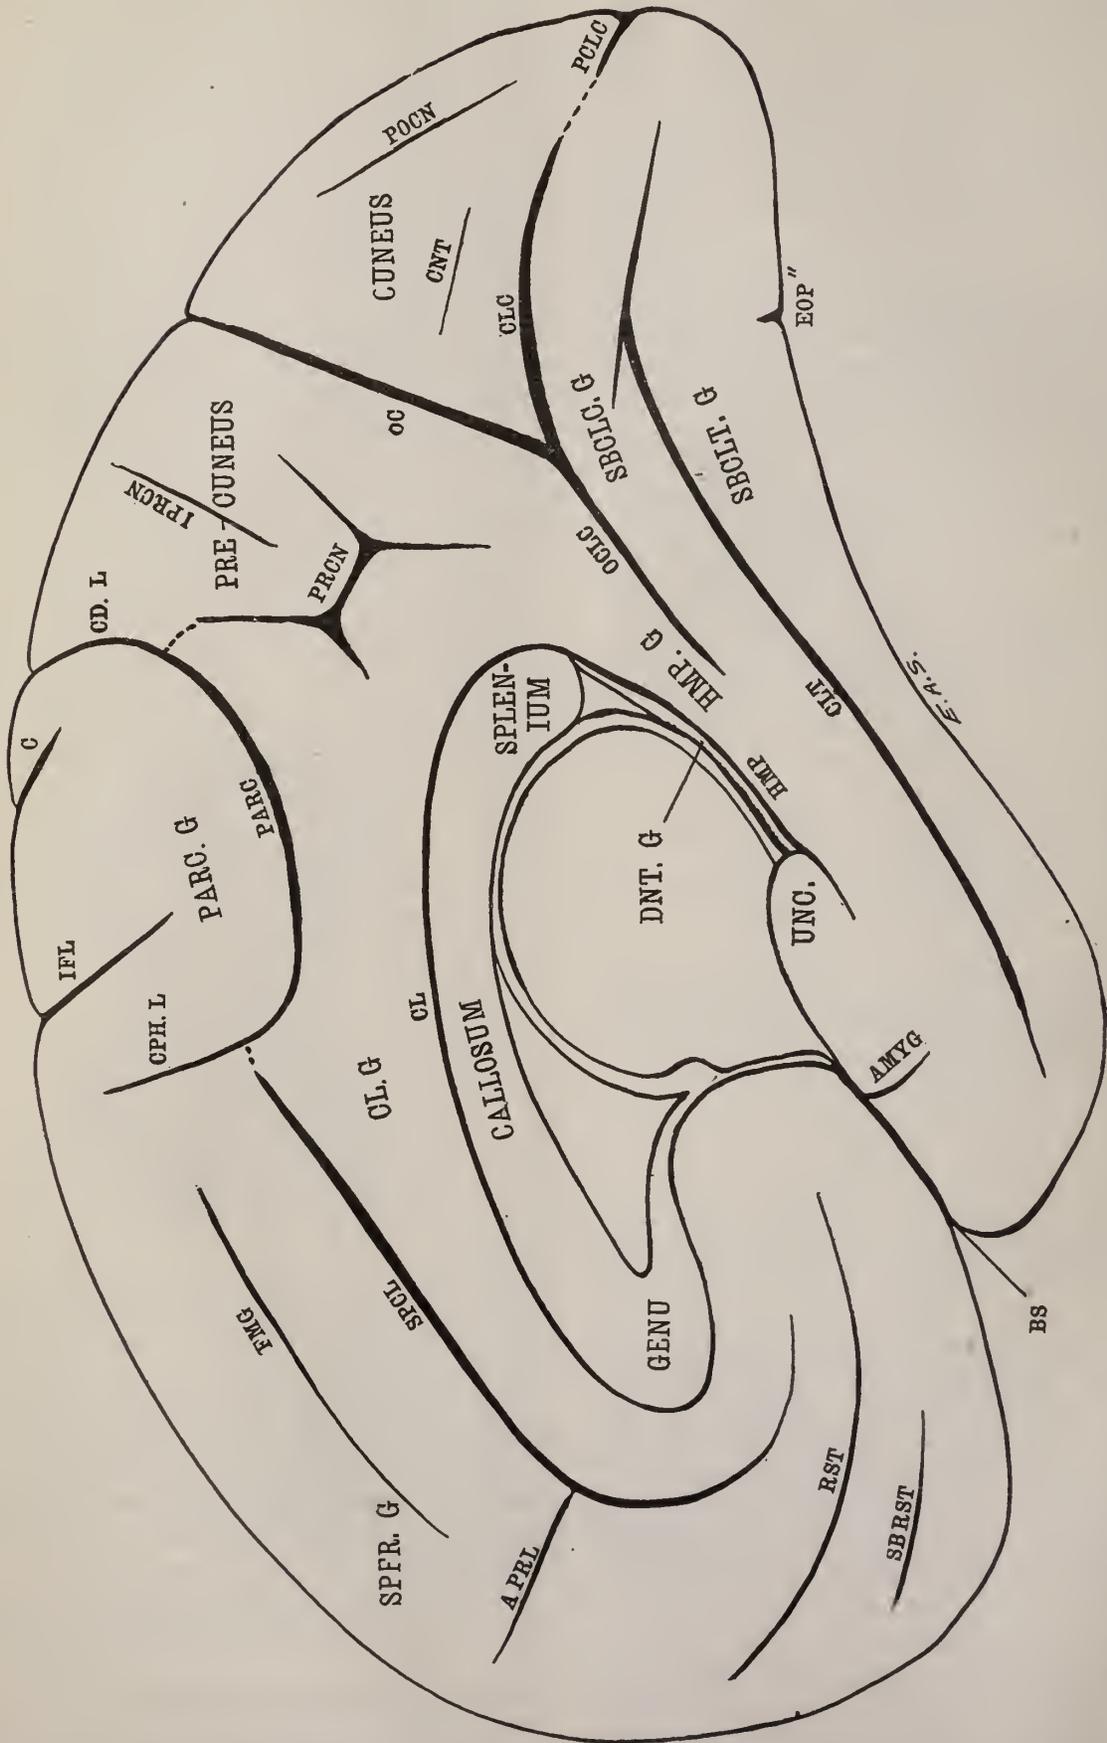

FIG. 5.—This is the writer's provisional schema of the fissures and gyres of the mesial cerebral surface; the intraparietal fissural elements are so variable as to be most conveniently omitted.

plane caudad of an unmistakable cephalic paracentral limb, while in the remaining nine per cent. this limb had become separated from the main paracentral stem by a narrow isthmus or slight vadum. But in all cases the inflected was situated caudad of this limb, whether separated or confluent, or, in other words, *the inflected indented and lay partly within the paracentral gyrus (or oval lobule, as Broca prefers to call it).* The reader will now understand the anomalous appearance of this region in Wilder's mulatto brain.

In sixty-three per cent. of all cases there was only one such limb or ramus, bounding the paracentral gyrus cephalad, as shown in Fig. 1. This arrangement occurred a little oftener upon the left half than upon the right.

In twenty-two per cent. there was an additional

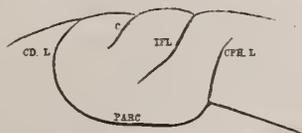

FIG. 1.—This arrangement is most common (63 per cent.). The cephalic limb is the only ramus, and is situated cephalad of the inflected.

ramus, *intraparacentral* in nature, and probably also in origin, situated just caudad of the inflected, between it and the central. Fig. 3 will show how at first glance such a ramus might be mistaken for the true cephalic

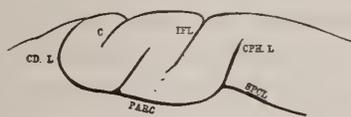

FIG. 3.—An intraparacentral ramus, just caudad of the inflected, was present in 22 per cent.; in all cases, however, the cephalic paracentral limb was also present.

limiting ramus, and one must be guided by its position with reference to the inflected, as well as by the size of the lobule thus marked off. This intraparacentral ramus may afford a possible explanation for the odd arrangement on Wilder's mulatto brain; the small paracentral gyre is limited cephalad by such a ramus, while the true cephalic limb failed to develop (see Wilder's Fig. 4766,

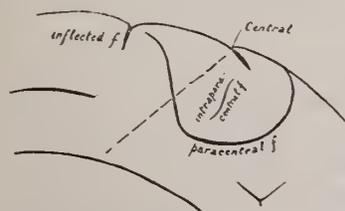

FIG. 4.—This figure shows the relations of the fissures as schematized by Professor Wilder.

Handbook, Vol. viii), so that the inflected fissure appears to lie wholly within the superfrontal gyrus. Fig. 4 is a copy.

In the remaining six per cent. the ramifications and disturbances of fissuration were so varied as not to allow readily of any classification. Sometimes there were two,

or even three, intraparacentral rami, or the paracentral itself was broken up into fissural segments.

As cited above, Eberstaller asserts that in fifty-five per cent. of his cases, the inflected (*S. praecentralis medialis*) anastomoses with the cephalic paracentral limb, or as he calls it, "*Anfangsstück der Pars posterior,*" and "*S. praeparacentralis.*" I found such confluence in only two of the 160 hemispheres, both being upon the left half. In nine other cases the inflected traversed the whole gyrus, effecting a conjunction with the paracentral stem; in all 11 cases of junction, or seven per cent. In the comparison of these percentages with Eberstaller's figures, the question of racial peculiarity must be excluded, since the brains which were examined by me were derived from representatives of many different races, white and colored, male and female, and varying in ages from twenty to seventy.

In the large majority of the hemispheres examined the inflected fissure ended upon the meson as well as upon the dorsum in a simple manner. In about sixteen per cent. it was observed that the mesial end joined some one of the *intraparacentral fissural elements*, giving the inflected a kind of bifurcated appearance. These intraparacentral elements are of not a little importance. There appear to be at least six fairly definite types, and nearly every lobule is marked by one or several of these. The longitudinal one, first described by Betz (13), and which is commonly bifurcated at one or the other end, is the furrow which is most common, and is most often joined by the inflected.

In the first fifty brains I also made observations upon the dorsal relations of this fissure. In the great majority of cases (eighty per cent.) the inflected was situated *cephalad of the supercentral*. In thirteen per cent. it was observed to indent a well-defined *inflected gyre* (Wilder), embraced by the dorsal radii of a bifurcated supercentral. This condition was symmetrical in three brains, and occurred oftener on the right half. In only six per cent. was the inflected caudad of the supercentral, *i. e.*, between the latter and the central fissure. In a few instances (number not noted) there was a superficial confluence with the supercentral, but a shallow vadum was always demonstrable.

Although Wilder's terminology has been generally employed in this article, there appears to be room for more discussion upon some of the terms. Broca (14), Mickle (15) and others consider *oval lobule* to be less objectionable than *paracentral lobule*, or *gyrus*, because this structure is not really "paracentral." For the terms *cephalic paracentral limb* and *caudal paracentral limb*, we might very well adopt *preparacentral* and *postparacentral*, retaining the name *paracentral* for the longitudinal stem.

In Fig. 5 I present a schema of the fissures and gyres on the mesial surface. It is a modification of Wilder's well-known schema, the changes being based upon the newer features which have become known and more or less accepted in the last decade.

EXPLANATION OF THE FIGURES.

The abbreviations used are the same for all the figures.

THE IMPORTANCE OF A KNOWLEDGE OF EAR DISEASE TO THE GENERAL PRACTITIONER.*

By WILLIAM H. THOMSON, M. D., LL. D.

It was with great pleasure that I accepted the invitation to read a paper at this first meeting of the Section of Otolology. Personally, I regard the institution of this section as an especially fortunate event to mark my term of the presidency of the Academy, because there is every reason in the nature of this important branch of our profession, and in the great progress which has been achieved in it, both to warrant and to welcome its admission into the family of the now eleven sections of the New York Academy of Medicine. With such a list of signatures as that which was appended to the request that this section be instituted, there can be no doubt of its coming success, so that I most heartily congratulate you on your auspicious beginning.

The selection of the subject of my present remarks, The Importance of a Knowledge of Ear Disease to the General Practitioner, is due to recollections from my own experience in general practice for over thirty-five years. It often takes years for us to learn the relative importance of things, and this is particularly so in medicine. Twenty-five years ago I should scarcely have said, what I now most decidedly affirm, that the general practitioner should feel a greater sense of responsibility when called to treat a case of ear disease than he need feel about affections of all the other special-sense organs put together. Thus, though it is a terrible misfortune to lose the eyesight, still, it is then one loss only. But a visit to a deaf and dumb asylum will illustrate the results of an otitis media in often a full half of the inmates, who became not only deaf but mute for life because, while they were children, the attending physician did not know how to treat the ears properly when they had scarlet fever or measles. Like many others, in my time, when I was engaged in family practice, a slight chronic otorrhœa in a child gave me but little anxiety. The mother or nurse was left to attend to that with a few simple and little-studied recommendations. I should no more think of doing so now than I would prescribe an evaporating lotion for an in-

*An address at the first meeting of the Section of Otolology of the New York Academy of Medicine, December 12, 1900.

cient hernia, for such dread consequences I have never seen as those which have come from a chronic slight otorrhœa. I prefer, therefore, to deal with my subject not in a systematic, but in a personal, reminiscent fashion, as it will abundantly prove the truth of Carlyle's saying that "Experience is a great teacher, but, alack, he demands such dreadfully high wages!"

A number of years ago a physician called me to see his young wife. He told me that she was the only child of well-to-do and very indulgent parents, and as a consequence she was ungovernable and emotional, often hysterical, in fact; that now she had headaches with afternoon chills and moderate fever, and that in these malarial attacks she would both cry and laugh and then become wilfully taciturn. I found her with a temperature of 101° F., with pupils natural and a perfectly regular pulse, but with a slowness in answering questions which, if I had had my wits about me, ought to have aroused my suspicions, instead of having them led off by the hysteria hypothesis of her physician, who was her own husband. I therefore instructed her anxious parents that she should go on with quinine, and assured them that her nervous symptoms should not excite alarm, for they were doubtless due to an attack of low malaria. At that time malaria could always be depended upon to come to our help whenever we were put to it for a diagnosis. Two days afterward her father came to my office to say that to ease their minds they had called in a gentleman who was much my senior and who then easily stood at the head of the surgical profession in the city, and, moreover, had attended the mother in her confinement when this patient was born. He was glad to inform me that Dr. — not only confirmed my diagnosis, but said that if she was his own child he would not have the slightest anxiety about her. That evening we both were hastily summoned to the father's house, which we reached together, and were immediately ushered into the sick room, to witness the patient in a few moments die before our eyes. We then learned for the first time that she had had a chronic discharge from one ear for some years, but that it had been "healed up" for more than a month. It can readily be imagined with what speechless mortification we both withdrew from that chamber of death.

It was not long afterward that I made another mistake in diagnosis from being misled by hysterical symptoms. A young man was admitted to my Bellevue Hospital service who gave an incoherent story of having been struck on the head in a fight in one of the liquor saloons in the unsavory neighborhood of that institution. I could find no evidence of depressed fracture of the skull or even of a bruise; his pupils were slightly contracted, but there were no signs of paralysis anywhere, though he staggered a good deal in his gait. He was not in a state of shock, but, instead, was very talkative, with alternate fits of crying and of laughing, while his breath smelt strongly of liquor. I concluded that he was simply drunk and ordered him to bed. Half an hour later he was found

dead. A fracture of the internal table of the right parietal bone, which had lacerated a branch of the middle meningeal artery with an extensive effusion of blood filling the lateral ventricle, explained his death, and, as was afterward learned, he had been struck with a sand-bag, which explained the lack of external evidence of injury. But what I wish to say is that I have now seen too many cases of purely emotional manifestations accompany the gravest organic intracranial lesions, such as abscesses, tumors, and particularly meningeal affections, to believe that in this case his hysterical behavior was solely due to alcohol. I would suggest, therefore, that any marked depression of spirits, with frequent weeping, accompanying persistent headaches in patients who have ear disease, always ought to put the practitioner on his guard and lead him to ask about chilliness, to watch the temperature, to note the pulse for too great slowness or irregularity, and especially to recognize any settled expression of anxiety, which to a practised observer is quite different from the expression of a whining hysteric.

But chronic ear disease may kill without doing so by the formation of an intracranial abscess. A lady, who was an old and valued friend, first consulted me for what she said was an ear trouble which had dated from childhood. I found a large pearly polypus completely blocking the right external ear, and at once advised her going to an aurist for its removal. She positively refused to do so because he would "hurt her so," and insisted that I should burn it out. I destroyed the growth very successfully by injecting it with glacial acetic acid at repeated sittings with a hypodermic syringe, and in the course of time her chronic discharge diminished so much that she ceased to attend, though I warned her not to fail to report every few weeks. Two years afterward, while on a coaching trip, she was exposed one morning to raw wind which set up pain in the ear. She at once returned to me, and I asked expert advice as to the local conditions present in the ear. Nothing but signs of ancient mischief with no new developments were discovered. The pain, however, persisted and extended to the side and back of the head, with occasional attacks of severe vertigo. Thus she went on for many months with every indication of intracranial mischief, but none of the specialists whom I called in consultation could locate the trouble sufficiently to advise any surgical interference. She died after sixteen months' illness, emaciated to a skeleton. Postmortem, the mastoid cells were healthy, but the attic of the tympanic cavity and adjacent portions of the petrous bone were carious, and there were only a few drops of pus found. Beyond was the most extensive development of pachymeningitis that I have ever seen, corresponding to the entire parietal and occipital surfaces.

This leads me to reiterate that it is not inflammation which makes pus, but bacteria, and, according to their kind, multiplying in an otorrhœa, will there be caused by the agency of one form a pervading infiltration which breaks through every barrier, bony or otherwise, and bur-

rows in pockets or enters blood channels for the most distant travels, while with another form its feeble toxin is resisted by Nature's efforts to circumscribe the invader by fibrinous exudates. A diseased ear may be infected by a pneumococcus, a streptococcus or a staphylococcus, a *Bacillus pyocyaneus* or a *Bacillus coli*. In a pleural empyema I always wish to find out whether it is a pneumococcus which has invaded, in which case the prognosis is better, or a streptococcus, in which it is worse. On that account general practitioners should seek the aid of bacteriologists when they find an otorrhœa resisting their measures of treatment, for by such help we may make some progress in the management of obstinate ear discharge, because I am sure that we have yet much to learn about the germicides which should be employed for different infections. Judging from the case of a pleural empyema, the pneumococcus in the ear is the easiest to deal with, and it is curious how often this organism invades the ears of children without any pneumonia being present.

The presence of intracranial organized exudates due to chronic ear disease often leads to serious consequences. One of the earliest manifestations of such, in my experience, has been the development of myoclonus, or persistent muscular twitching in different parts of the body, notably the extremities, and particularly annoying when the patient is dropping to sleep. Some neurologists speak of this myoclonus as spinal in its origin, and term it spinal epilepsy. I think that this view is wholly incorrect and that these muscular twitchings are always indications of a cortical irritation which too often is a precursor of true epilepsy. I feel confident that epilepsy due to ear disease is more common than is usually recognized, and I always keep in mind this possible origin in my first examination of a case of this disease, on account of the bearing it then would have on the treatment. When it is so traceable, the case is then equivalent to epilepsy following trauma in depending primarily on an organic irritation of the cortex by what is virtually cicatricial tissue.

Some cases of otorrhœa exciting acute mastoiditis may then assume disguises which can deceive the very elect. I was called last winter as the third consultant in a case of this kind, the patient having been seen before by two of our most eminent men. She had long suffered from ear disease, and the first gentleman diagnosed an intracranial abscess and advised an immediate operation. Soon after his visit acute parotiditis developed with extensive swelling, which led the second consultant, as I was told, to pronounce it a case of mumps. Three days afterward, when I was called in, there could be no hesitation about the diagnosis, because of an unmistakable group of basilar and pontine symptoms. I advised an operation, but with little hope of a favorable result, as the fatal sequel showed. I mention this incident, however, mainly in connection with my experience with the supervention of parotiditis in typhoid fever, for so far it

has invariably been associated with an antecedent invasion of the ear.

Finally, the subject of vertigo is one about which every practitioner sooner or later will wish to know all he can. I have paid some attention to this subject, and will briefly give my views now for what they are worth, about its chief varieties and their clinical characteristics. I would classify the varieties into

1. The gastric, or digestive.
2. The cardiovascular.
3. The ocular.
4. The aural.

The digestive variety supervenes upon gastro-intestinal derangements, and its peculiarity is that the patient is greatly annoyed and vexed with it, but not much frightened.

The cardiovascular variety, when dependent upon weakness of the heart, always has nausea as its accompaniment. When due to cerebral endarteritis it has not, but, instead, frequently excites a feeling of foreboding of mischief. It is generally very transient.

Ocular vertigo is interesting in having a purely psychical basis. It does not occur in the dark, for to have it come on, the eyes must be open and looking out, and it may be relieved by closing them. It is the vertigo which causes the head to swim at the brink of a precipice. Its explanation is that the general muscular tonus which keeps us in position has for one of its main elements the information which the eyes are constantly, though unconsciously, giving us of our surroundings, and when the eyes suddenly find a lack of surroundings, the muscular system as suddenly fails to receive its customary stimulus to maintain tone, and hence general muscular tremor immediately sets in. It must always come as a surprise, for otherwise we can guard against it, as in the dark, by the help of the muscular sense and of the sense of touch. The most certain place to experience it is on the top of the great pyramid of Egypt. I found there that, though I knew I had below me the most solid building on earth, with a base of twelve acres, yet to right, to left, before, and behind, my eyes for the first time looked into pure nowhere. With shaking legs I sought the centre of the great flat top, which equals this room in area, and there forthwith squatted. It was curious how soon a few steps on the sands below gave me back my former muscular quiet, while I watched a polite French priest, ere he was quite down, try to touch his hat to me, with every symptom of *paralysis agitans*. Derangement of the oculomotor apparatus by disease causes this form of vertigo by its mixing up the images of our surroundings and putting them into unaccustomed relations to us.

The vertiginous sensation, however, which causes the most positive disturbance of all, is the aural variety. In that marvellous mechanism of the semicircular canals we carry with us a fluid level the slightest tip of which is instantly transmitted to the most centric station of nervo-muscular regulation, whereby we know our position in

space and behave accordingly. Hence the least derangement here at once causes alarm. In pronounced cases of aural vertigo there is no scare equal to it for causing a cold sweat. The patient feels as if he were being dropped into a bottomless pit, while catching hold of things, or even lying down, gives but little relief. Everything seems to be giving way or turning around. Its invariable accompaniment, therefore, is fear, which may long outlast the vertigo itself, rendering the patient a chronic coward who dreads all going about. This characteristic is often mistaken for the nervousness of a hypochondriac dyspeptic, and unavailingly prescribed for through the stomach, or else mistaken in adults for some serious condition of the cerebral blood-vessels. All cases of vertigo with a predominant feeling of alarm, or with a story of onset while the patient is recumbent, should lead to a careful examination of the organs of hearing, when a condition may occasionally be found which has nothing to do with organic disease, though usually it has. Thus, a man was once brought to me for locomotor ataxia, as he could not walk across the room without support. I soon found that he did not have a single symptom of tabes, not even in his gait, but both ears were plugged solidly with hardened wax, and so I told his attendant that he could cure this locomotor ataxia with a syringe, which he soon did. Another similar case with the same diagnosis was once sent to me from a neighboring State.

I need not say that throughout these desultory remarks I have not thought of addressing otologists, but rather have kept the general practitioner steadily in view, if only to emphasize his need of a thorough acquaintance beforehand with the critical situations in which he may find himself when dealing with a case of ear disease. At first sight, nothing seems omitted to insure safety for the contents of the cranium, if separate isolation within solid walls, with only the smallest and best-closed apertures, are considered. But, as in the Greek fable which represented Achilles invulnerable except at his heel, where at last he was fatally struck, so by the little passage through the ear we always have a possible hidden inlet for disease and death. When once the enemy makes his lodgment in the intricate recesses of that tract, his further fatal progress may be the most difficult to detect of all the perils that can befall us, for the royal organ threatened cannot be palpated like an abdominal, or listened to like a thoracic, viscus. Both alertness and skill are needed to deal with a process which, on the one hand, may have all the intractability of an infected mucous membrane lining a narrow tube from the Eustachian orifice up, and, on the other, may develop into what is equivalent to a virulent osteomyelitis in the mastoid area, not to mention that in the roof of the tympanic cavity we have the thinnest bony plate in the body to be sometimes the only partition between the brain and a culture teeming with deadly organisms. With our present status in knowledge, every institution of medical education should insist that its students be most practically trained, first in the methods

for examination of the ear, and then in the most efficient methods for the early treatment of its affections. We need not be surprised at the imperfect diagnoses of many otherwise experienced practitioners, because a satisfactory inspection of the tympanum alone is neither simple nor easy. It requires a good deal of practice for any one, not so much to see through a speculum into this dark hole, but, what is quite another matter, to *perceive* what he is seeing. Many a physician, when trying it with a screaming and struggling child, makes believe at the end that he has seen it all, when he knows that he has seen nothing except, perhaps, some pus. If, therefore, the general practitioner finds in time that he is making no headway, never can he be morally justified if he fails to ask an otologist to help him.

SOME OBSERVATIONS UPON SPECIALISM IN THE ARTS AND THE SCIENCES GENERALLY, AND UPON SPECIALTIES AND SPECIALISTS IN THE SCIENCE AND THE ART OF MEDICINE PARTICULARLY.

BY WILLIAM BODENHAMER, A. M., M. D., LL.D.,

NEW ROCHELLE, N. Y.

THE subject of specialism is now being discussed *pro et con.* by able writers, and, as it is well worthy of observation, the writer feels disposed on this occasion to present also to the profession some views upon the same subject, *pro tanto.*

Specialism in General.—Now, the fact is familiar to all that civilization, with its accompanying increase of population, wealth and refinement, is universally followed by the microscopical division of labor, and the rending into greater or smaller parts of every art, science, pursuit, or calling. The natural tendency to and the necessity for just such judicious separation are self-evident. The truth is that the most important and most valuable results have been effected by such concentration of purpose and of practice upon one particular subject, part, or point, for it tends greatly to the increase of knowledge, and by improving a part leads to the gradual perfection of the whole. The future, therefore, of specialism generally will continue just so long as civilization and the arts and the sciences themselves exist.

Specialism in the Science and Art of Medicine.—It can be abundantly verified by the writings of Hippocrates and Galen, and especially by those of the latter, that specialties and specialists in medicine and in surgery existed from time immemorial. Indeed, the science and the art of medicine, which embrace all that relates to the human organization, its diseases, injuries, and malformations, have not escaped this natural divisionary law, for even at a very remote period of antiquity the first and grand division of medical science into medicine and surgery took place; the latter, strangely and singularly enough, passed, by hook or by crook, into the hands of the

illiterate knights of the razor, who as barbers and as surgeons practised both shaving and surgery, and who learned and adopted the language of the shambles in giving names to the different anatomical parts of the human body, such as *gut, guts, gutted, gullet, belly, shin-bone, buttocks, fundament, piles*, etc. The use of these vulgar names, which emanate from and savor so strongly of the shambles, by some reputable surgeons of the present day is both disgusting and barbarous, and should be shunned as being a constant and an unpleasant reminiscence of the low estate into which their once beautiful and noble science had fallen. Then, why should we continue to employ these low and vulgar terms when we have such appropriate, elegant, and classical ones as substitutes for them?

Subsequently, however, to this desecration and degradation of surgery, it in process of time was ultimately wrested, as it were, from the barbers and placed in more noble and proper hands; and from that time to this how grand and how brilliant have been its results!

The Surgery of the Present Day.—In Great Britain, more especially perhaps than in any other country, the physician, or doctor, many years ago always looked down upon the surgeon as being beneath him in rank. But the tables are now being turned, and the surgeon of to-day, with his generally superior knowledge of anatomy, which is and always must be the very fundamental part of medical science, is daily encroaching upon some of the physician's claims; these infringements, however, have a certain and a positive limit, beyond which they cannot go; hence the physician is as necessary in his department as the surgeon is in his. Indeed, they can never from necessity be entirely severed; they are like the Siamese twins, and cannot live apart.

Our knowledge of anatomy has now been brought to such a degree of accuracy as to reflect honor upon its promoters. The surgeon now in possession of this valued boon, together with the aid of anæsthesia, is inspired and emboldened to attack viscera or parts which formerly would have been shunned or attacked with the gravest apprehension. The surgeon is now no longer afraid of penetrating as deep as the seat of the disease may require, like a well-skilled pilot; his instrument glides over, between, and around the most essential parts of the body without injuring beyond repair their delicate substance or structure. Indeed, surgery is the most tangible and the most scientific branch of medicine.

Specialism in Medicine is Essential.—Now, the necessity for and the propriety of specialties in medicine are, for the most obvious and cogent reasons, that the science of medicine extends its inquiries over so vast a range of knowledge, and comprehends such a multitudinous mass of detached facts and observations, that it includes a number of distinct departments. In any one of these the medical inquirer may employ his industry to advantage, either in collecting the valuable observations of his predecessors upon the subject or in augmenting them by his

own, using his own judgment and discrimination in their selection and arrangement. Now, if any medical man, impressed with such views and possessing a comprehensive knowledge of all the departments of the science, should direct his special attention to such a one as his inclination, genius, and particular circumstances led him to select, he could scarcely fail, by study and by practice, to simplify, to enlarge, and to improve it. But as a necessary consequence, unless he is accurately acquainted with the principles of the entire science, he is utterly incapable of elucidating or practising it successfully in any one of its parts; for it is the establishment of all the principles of the science alone, as a whole, which can be truly serviceable to him in the practice of any one branch, and can alone preserve him from the blunders and the disgrace which inevitably await a partial and a contracted knowledge of it.

It cannot be denied that specialism in medicine is productive of vast good, provided, as has already been observed, the physician or surgeon practising any one branch has in the first place that general knowledge and scientific attainment which are absolutely necessary for the efficient practice of medicine in its most comprehensive sense. Now, as an evidence of its importance and value, there are now, and have been for many years, in the cities of London, Edinburgh, Paris, Vienna, Berlin, Rome, New York, Philadelphia, and Chicago some of the most profound specialists in the world, who are sought after and universally considered superior in their different professional specialties.

Some years ago the writer made the following remarks in a medical journal, and they may be worth repeating here: "It may be well to remark that, with regard to specialism in medicine, the fear is that too many who practise it are not competent, being, as it were, mere specialists. They are not qualified by experience to practise medicine in general, which is positively a prerequisite, a *sine qua non* to the successful practice of a single branch of the science. To render the specialist competent to practise in any one branch of medicine, he requires not only a classical education, and a general knowledge of the various branches of the science, but engrafted upon this a minute, accurate and professional knowledge of the peculiar branch of practice in which he is engaged. Truly, the best specialist is the one who has previously practised medicine in general for some time, or who has taken the advantage of a thorough course of clinical instruction in a postgraduate medical school. The general practitioner, as a rule, is considered to possess greater advantages in general medical knowledge and experience than the mere specialist, and cannot under any consideration be dispensed with; consequently, he is the more important and useful of the two. Now, it is not every upstart that can go through with the eight notes merely, that is competent to teach and to render music scientifically and successfully, or that is capable of constructing a gamut; neither is every medical tyro, who has just passed through

the green-room, qualified to practise a specialty intelligibly and successfully.

Anorectal Specialism.—It has always heretofore been an enigma why the diseases, injuries, and malformations of the anus and the rectum should not be treated as a specialty. Are not these affections as numerous, as important, as painful, and as serious in their consequences as are those of the uterus, the throat, the skin, the lungs, the eye, the ear, etc.; and do they not equally require as intelligent, as scientific, and as skilful medical and surgical treatment as those which are now so successfully and so brilliantly treated by able and expert specialists in their several spheres or departments?

The truth is, and it cannot be denied, that many members of the medical profession, both at home and abroad, as will be shown hereafter, are more or less opposed to anorectal specialism. While they seem to tolerate it in some other branches of the science, they ignore it in that of the anus and rectum, and the singular, unreasonable, and frivolous argument they advance against it is that the rectum is, and always has been, the same "crooked" and obscene domain alone of charlatans of every grade and complexion, and that they do not like the association, etc. But are we never to be relieved of this horrid incubus, or must we expect the survival of this affliction to be forever a permanent souvenir or nuisance? And, furthermore, it is declared that special practice in this dark, obscure, and obscene organ is both disgusting and detestable to men who profess to be scientific and lovers of their profession, the healing art. It is true that this kind of practice is by no means inviting and pleasant, but rather repulsive; yet it must and should be considered and admitted by all to be of the highest importance, for upon it the life, the health, the comfort, and the convenience of so many much depend. No subject, however, of whatever character, should for a moment be considered undignified or unworthy of anxious thought and attention, if it involves such serious consequences or has for its object the improvement of the healing art or the extension of our knowledge of Nature's operations. Indeed, there is no other standard known by which to determine the dignity or respectability of any branch or specialty of medical science than its capability of saving life and relieving pain and suffering. The rectum has for the last forty-five years been gradually cultivated by eminent men of learning, science, and skill, both in Europe and in America, but not wholly or particularly as a specialty, however. Their labor in this field has been of great advantage, for it has incidentally led to and encouraged specialism in this department, which would now seem to be completely specialized, for a society has lately been formed, the first of its kind, for the special medico-surgical treatment of the anorectal affections, composed of learned and skilful physicians and surgeons, which they, singularly enough, denominate the "Proctological Society." The writer has not the honor of being a member of this society, but, with a few exceptions, ap-

proves most cordially of its objects. He can speak *ex cathedra* upon the subject of the anorectal affections, having for fifty years of his life devoted more or less time to its consideration, as his several treatises upon the subject and his numerous medical journal publications prove.

Now, who will deny that these numerous affections should be entitled to a separate and special consideration; and who will say that those who practise such a specialty have not the privilege, if they choose, of forming themselves into a society?

The writer must observe here that he cannot refrain from calling attention to the unfair remarks on specialism in a highly valued medical journal, as will be explained in what follows.

To prove how opposed some of the medical profession of Great Britain are to specialism in medicine and to its spread, the writer will present what one of the most able and most popular medical journals in Great Britain, the *British Medical Journal*, says, as commented on in the *Journal of the American Medical Association* for May 13, 1899, as follows:

"We are at a loss to know whether or not to feel offended at this sarcastic reference to one of our young societies by the *British Medical Journal*. In its issue for April 29th, under the caption 'Specialism in the United States,' it says: 'The development of medical specialism in the United States suggests that in that enlightened republic a condition of things may in time be brought about like unto that which prevailed in ancient Egypt, where the human body was, as it were, pegged out in claims, each of which was allotted to a particular class of specialists. Among the most recent indications of this tendency may be noted the formation of an "American Association of Proctologists," which is to devote itself to the cultivation of rectal surgery, a field which it appears has been "very much neglected by the physician and the general surgeon." This interesting body is convened for the first time to debate *circa ardua recti* at Columbus, Ohio, during the forthcoming annual meeting of the American Medical Association. A body whose scientific enterprise extends somewhat higher is the American Gastro-enterologic Association, which will hold its second annual meeting in Washington on May 2d, immediately after the meeting of the Association of American Physicians.'"

The writer will say that this satirical effusion of the *British Medical Journal* must evidently have been the emanation of a puny, sarcastic scribbler, fed by the scintillations of his low wit and the distortions of truth. The unfair and the ungrateful allusion to Egypt, the mother of the sciences and the arts, and to the ancient noble Egyptian and Arabian physicians, especially those of the famous cities of Alexandria and Carthage, is equally unjust, undeserved, and unbecoming. We should never forget or lose sight of those ancient, noble Greek, Arabian, Egyptian, and Roman physicians, to whom we owe so much, the representatives in their times of the

most intellectual nations of mankind. The writer will merely remark that the idea of pegging out the human body to infinity in claims for specialists is preposterously absurd, or, in other words, absurdly absurd; hence the *British Medical Journal* may at once dismiss all its idle fears that "the enlightened republic" will ever fall into that journal's absurdity. Common sense teaches us that a just, a rational, and a proper limit must be made to specialism; it cannot be pegged out *ad infinitum*. The writer will now conclude his observations upon specialism by quoting the good old Latin maxim, so replete with truth and so applicable to our subject: *Cuilibet in arte sua credendum est*.

December 15, 1900.

A CONTRIBUTION TO
THE SYMPTOMATIC TREATMENT OF
PULMONARY TUBERCULOSIS.

BY J. R. L. DALY, M. D.,

NEW YORK,

FORMERLY RESIDENT PHYSICIAN TO THE SETON HOSPITAL FOR
CONSUMPTIVES.

ASIDE from the progress made in the hygienic management of pulmonary tuberculosis, the treatment still remains to a great extent symptomatic. In my experience with this disease in a hospital devoted exclusively to this class of patients there were three symptoms particularly which I found it difficult to control, namely, diarrhœa, certain varieties of cough, and disturbances of the stomach. Of these, I desire to discuss the two latter, as, fortunately, I am able to contribute a few suggestions on their treatment which have proved of value in my hands.

There is a variety of phthical coughs which heretofore has been most intractable to remedies of all kinds. This is a persistent, hard cough with but little mucus, of a tenacious character, which is expectorated with much difficulty. Owing to its persistence, it is very exhausting, robbing the patient of his night's rest.

After a conscientious trial of various remedies I consider it of importance to call attention to an old drug which I have practically put to a new use. Every physician knows that camphor is a respiratory stimulant, but I have failed to find any special reference to its use in this class of cases. I have found it of advantage to combine camphor with creosote and heroine in the proportion of camphor, two grains, heroine, one twelfth of a grain, and creosote, one drop. The creosote has been added because of its quality as a disinfectant and deodorizer to the respiratory tract. I do not regard the small dose of one drop as sufficient to exert any but a feeble action in this respect, but I have refrained from using more of it because of its tendency to disturb the stomach; however, the breath is rendered less objectionable, this being due in a measure to its antiseptic and deodorant effect. The other constituent of this formula, heroine, was added because

of its well-known action in allaying bronchial irritation and regulating the respiratory mechanism by diminishing the frequency of respiration and increasing the volume of inspiration. I have preferred to administer this combination in pill form, because of the volatile nature of camphor, as well as the unpleasant taste of camphor and creosote when taken in solution. These pills have been manufactured for my use by Messrs. Schieffelin & Co., of New York. While in the relief of the milder coughs I have been able to rely upon heroine, I have found that this drug alone does not suffice in the severe variety mentioned above. It is here that this combination afforded me results which I had been unable to obtain previously with any other single remedy or combination of remedies.

Below will be found a description of a few cases which were markedly benefited by this pill. In nearly all the cases cited, as well as in the others in which it was tried, I had previously prescribed several different expectorants and expectorant mixtures, but none with the success which attended the administration of this combination.

CASE I.—The patient had had tuberculosis three years. The most troublesome symptom was the hard, persistent cough, which made it impossible for the patient to sleep except at very infrequent intervals. The usual expectorants were prescribed, including codeine and heroine, as well as inhalations of creosote and benzoin, with but small success. Heroine gave slight relief for a time, but its effect rapidly wore off, and the symptoms became as distressing as before its administration. I then gave one pill of heroine, camphor, and creosote, *t. i. d.* and at midnight, and was glad to find that in two days the cough had lost its hacking character, the mucus was expectorated with ease, and the patient was enabled to enjoy a comfortable night's sleep. This improvement was permanent.

CASE II.—The patient gave a history of tuberculosis for a year and a half, and during that period had a severe cough. At first heroine afforded marked relief, but later on, because of the extension of the process, the cough increased in intensity and became almost continuous, paroxysms occurring about every two hours, with particular severity during the night. As in the last case, the usual expectorants failed to give more than momentary relief, and, having gone almost through the list of remedies indicated, I prescribed the above-described pill, *t. i. d.* and at midnight. This had the desired effect in loosening up the mucus and lessening the paroxysms in frequency and severity.

CASE III.—In this case there was a history of tuberculosis for about two years. The patient complained of inability to bring up mucus, except in very small amounts and only after much effort, and suffered intensely from dyspnœa in consequence. Examination of the chest revealed a large amount of mucus in the bronchi. The administration of the pill of heroine, camphor, and creosote, every five hours, had the desired result in facilitating expectoration and making the cough less troublesome, and, after removal of the mucus, marked relief of the dyspnœa ensued.

CASE IV.—The patient had had tuberculosis a year and a half, and chronic emphysema for six years. The

object in this case was not so much to lessen the severity of the cough as to relieve the dyspnoea due to the emphysema. The pill in this case seemed to be of more benefit than heroine used alone, and this was due no doubt to the stimulating effect of the camphor on the respiration.

CASE V.—There was a history of tuberculosis for three years and a half. During most of that time the patient had had cough which gradually became worse, though responding for brief periods to various expectorants. He has been taking the heroine, camphor, and creosote pill for four weeks, and I am pleased to note that since then he has experienced great relief, the cough causing discomfort only in the morning, on rising. Besides the amelioration of the cough, I also noticed that the patient was considerably relieved of that feeling of nervous depression so often found in those suffering from tuberculosis. This of course was due to the camphor in the pill.

CASE VI.—There was a history of tuberculosis for four years. Cough had been present for about that length of time, and became more troublesome at intervals. Since taking the pill, the patient has been much more comfortable. I cite this case, not so much on account of the relief from the cough afforded by the pill, but, as in the preceding case, because of the abatement of the nervous depression from which the patient suffered severely.

To sum up, I believe this formula of heroine, camphor, and creosote to be without doubt superior to any I have ever used in the treatment of cough. In most of the cases in which the pill was prescribed the cough was of a very obstinate character, but I see no reason why it could not be used in other cases of cough. I do not believe it is advisable to prescribe this pill in cases in which the stomach is disturbed, because of the stimulating effect of the camphor upon the gastric mucous membrane.

I have referred to the benefit derived from its use in cases of nervous depression found often in those suffering from tuberculosis. This quality of the camphor element in the pill makes it of great value, and, when we have present this condition combined with the distressing cough, I believe the heroine, camphor, and creosote pill to be absolutely the best prescription that can be used.

The other symptom referred to in the beginning of this article, which I have also found extremely difficult to combat in phthisical patients, is disturbance of the stomach. In many cases this disturbance of the stomach is indirectly due to the cough, either by reason of the foul expectoration, causing nausea, or, in cases of severe cough, the effort required to expel the mucus, also causing vomiting. Of course, in this class of cases the logical treatment is to relieve the cough, and no relief can be obtained from the use of remedies given for their local effect upon the stomach; but in most instances, where the cause is a local one, due to disturbance in digestion or ulceration, and the stomach is irritable in consequence, the greatest relief can be obtained from such local remedies as bismuth, cerium oxalate, etc. In such disorders I believe bismuth, owing to its astringent and sedative properties, to be the best remedy of those in use, particularly if

employed in combination with others, each being given for some particular effect. That which has given me the best results is one having the following formula:

℞ Bismuth subnitrate..... 15 grains;
 Guaiacol carbonate..... 1 grain;
 Heroine. 1/2 of a grain.

M.

Heroine has been selected as one of the constituents of this formula, because I have found it to be possessed of some analgetic power; the guaiacol carbonate, because in small doses it has a tonic effect upon the stomach, and facilitates the proper action of that viscus. In all, I have used this formula in about forty cases, and to give examples would mean a repetition of symptoms and results. I believe it sufficient to say that in every case in which this tablet was prescribed, when the cause of the disturbance of the stomach was a local one, the result obtained was entirely satisfactory, relief from the nausea and vomiting being afforded after the use of from four to eight tablets, one being given after each meal.

In the use of this tablet care must be taken to prevent the constipation which the bismuth may produce. In cases in which the nausea and vomiting are due to disease of other organs, such as nephritis and cirrhosis, it is of little use to prescribe local medication, as the relief obtained is slight and lasts for only a brief period.

682 UNION AVENUE.

A CASE OF ACROMIOCLAVICULAR DISLOCATION AND ITS TREATMENT.*

By BERNARD E. HENRAHAN, M. D.,

NEW HAVEN, CONN.,

MEMBER OF THE CONNECTICUT MEDICAL SOCIETY, NEW HAVEN MEDICAL ASSOCIATION, ETC.

DISLOCATION of the acromioclavicular articulation is usually described as a dislocation of the acromial end of the clavicle, but it is really a displacement of the acromion process of the scapula, the distal bone being the one usually spoken of as the bone dislocated. In the great majority of dislocations of this joint, the acromion process is displaced downward and inward beneath the clavicle, the outer end of the latter bone riding on top of the acromion, and the cases are very rare where dislocation of the acromion takes place upward with the clavicle engaged beneath the process. This fact is readily explained when one studies the structure of the joint and the character of the injury received. The articular ends of the bones are two small plane surfaces that are held in apposition by a capsular ligament, which completely surrounds the articular margins, and is so loose in all positions of the joints that the acromion is not tightly held to the clavicle. The looseness of the capsular ligament

*Read before the New Haven Medical Association, November 7, 1900. Read by title before the New Haven County Medical Society, at New Haven, Conn., October 18, 1900.

permits of a fair range of motion of the scapula upon the clavicle as the former glides upon the thorax, not only in the forward, backward, upward and downward movements, but also in a rotary direction, which is called for in the complex movements of the upper extremity. As the joint is superficially placed, some protection is given to it by the aponeurosis of the trapezius and deltoid muscles, the fibres commingling with those of the upper surface of the ligament, while beneath, the clavicle is firmly bound down to the coracoid process by the short conoid and trapezoid ligaments, which have, however, no relation to the joint proper. In all motions in which the shoulder is engaged, the scapula moves upon the outer end of the clavicle, the latter moving in unison upon the sternum, the function of the acromioclavicular joint being principally to preserve the obliquely forward direction of the glenoid cavity. If there was no such joint, when the scapula slid forward on the thorax, the glenoid cavity and shoulder joint would point upward, and when the scapula slid backward the shoulder joint would move outward. The joint governs the different movements of the scapula, and keeps the glenoid cavity at all times in a forward position. In keeping the joint in position, there is only a small edge-to-edge articulating function of each bone, and when the joint is injured in a manner in which the joint is always exposed from its superficial relations and its position in the body, a disturbance of these small joint relations is easily brought about. The injury that may produce a luxation of this articular union is a blow of sufficient force on the back of the shoulder, as, for example, a heavy weight falling from above and striking the shoulder when the body is bent forward, or an accident in which the body is thrown with more or less violence, striking the back of the shoulder against some solid object. If the blow lands on the front of the shoulder a fractured clavicle is the result, whereas, if the blow is struck posteriorly over the acromion or spine of the scapula, the dislocation under consideration generally takes place. A blow over this particular area is somewhat infrequent. This accounts for the fact that, in the majority of cases, the blows sustained by the shoulder usually result in a fracture of the collar bone. The injury is, however, of sufficient frequency to make it one of the surgical pathological phenomena for which the practitioner must be constantly on the alert. The recognition of the luxation is not difficult, yet it presents, on first sight, a deformity so akin to that of a dislocation of the humerus forward, that an unpractised eye may have some doubt in determining the precise lesion. The rotundity of the shoulder will be destroyed, and the projection of the overriding clavicle may be mistaken for the apparent projection of the acromion in shoulder-joint dislocation. When it is remembered that the shoulder joint is carried slightly forward and inward; that the hand of the injured side may easily be carried to the shoulder of the sound side when the elbow is on the chest; that by following the line of the clavicle the normal rela-

tions of this bone with the acromion are disturbed, the clavicle being on top; that there is no marked fossa above the head of the humerus; and that the projection of the clavicle is fully one inch within the line of the humerus, one cannot fail to recognize the actual condition. The treatment of the luxation will necessarily consist in reduction and retaining the limited articular surfaces in position until union of the torn capsular ligament is established. The former is usually easy; the latter most difficult. Reduction can be effected by pushing upward and outward on the arm. This raises the glenoid cavity and scapula, and, by pressing down the overriding end of the clavicle into its normal position and relation with the acromion, the deformity is overcome. This may be done with or without anæsthesia, according to the force-resisting powers of the patient. The retention of the bones in position now becomes a matter of some difficulty. Desault's dressing is usually recommended, but it proves inadequate for the purpose—the deformity being resumed after a lapse of a few hours, when the bandages have stretched and muscles are relaxed. Adhesive plaster dressing has the disadvantage of causing erosion of the skin in most patients before ligamentous union takes place. This erosion is at least a source of great annoyance, and the inefficiency of the method as a curative agent is rendered rather evident by Stimson's information that "recurrence can be readily detected through the plaster by the finger or the eye." Some text-books even go so far as to say that the retention of the bone in place after reduction presents so many difficulties that it is not worth while to attempt it. With this, however, I cannot readily agree. The following is a method of treatment which has worked well in the writer's hands, and seems to meet all requirements. The application may be set forth in the following case:

A. S. B., aged thirty-eight years, of strong muscular development, while in a barroom brawl met with the accident referred to above. A temporary dressing was applied, and the patient transferred to the writer on the following day. Upon examination, there was found considerable swelling, yet not sufficient to mask a marked prominence of the outer end of the clavicle; the acromion could not be felt, and the shoulder was depressed and approximated to the middle line of the body. There was also an apparent lengthening of the right arm. Since it was necessary to determine if there was not a fracture associated with the luxation, and as the patient suffered considerably, an anæsthetic was deemed advisable. No fracture or other lesion was found. The writer is indebted to Dr. Henry H. Smith for kindly advising and assisting in the reduction. A wedge-shaped pad of absorbent cotton rolled in a towel was placed under the arm; the apex was pressed firmly into the axilla, and a Desault bandage applied. This kept the bones in position, and the patient complained very little of pain from the tight dressing. The dressing was reapplied on the seventh and fourteenth days; on the twenty-first day it was discarded altogether and a spica of the shoulder substituted for one more week. All dressings were then removed. Some pain was felt on the right side of the neck after the re-

removal of the dressings. This disappeared on massaging the parts once in two or three days for several weeks, and the patient is now in excellent condition, having full use of his arm, without any pain or deformity in the shoulder.

The good results obtained in this case and the simplicity of the application would recommend the method as a suitable one in the treatment of this refractory lesion. A method of treatment introduced into the Jefferson Hospital by Professor J. H. Brinton, of Philadelphia, is of interest in this connection. It consists of a pad placed in the axilla, a folded towel of heavy texture placed over a broad area at the site of injury, and a strap two inches wide thrown across the shoulder and under the elbow. A pad of absorbent cotton prevents too great pressure on the elbow. The strap is drawn as tightly over the shoulder as the patient can well bear; the point where greatest pressure is exerted is between the articulation and the root of the neck, so as to control both the scapula and clavicle, and the trapezius muscle, without causing the pain of pressure directly over the site of injury. A single retaining bandage passed under the opposite axilla, prevents the strap from slipping off the shoulder. The placing of the wedge-shaped pad under the arm with the broad base downward makes it possible to exert pressure in the line most desirable, upward, outward and backward, raising the glenoid cavity and with it the scapula, while the clavicle is pushed downward by the same force, and thus prevented from again riding up over the acromion. A roller bandage around the chest anchors the arm and elbow to the side, the buckle of the strap not being covered in, so that the strap can be tightened, if necessary, without disturbing the rest of the dressing.

608 DIXWELL AVENUE.

SEXUAL INTEMPERANCE.

BY JENNIE G. DRENNAN, M. D.,

ST. THOMAS, ONTARIO, CANADA.

AT the present time we are too apt to confine our remarks to liquor intemperance and overlook the fact that there are other forms of intemperance which are just as pernicious to the welfare of man. Either from ignorance or from false modesty we have allowed this evil of sexual intemperance to pass unmolested. Under the cover of a legal marriage it has been at liberty to cause all manner of suffering without being attacked by those who ought to and do have the health of the world in their hands. Its evils have not been held up to the public gaze like those of drink, food, dress, and pleasure intemperance. Nay, many of the reformers in these other lines are as guilty of this one evil as those who do not in any respect uphold the tenets of temperance. This has been the one condition in which man has been allowed free exercise of his own will. It has been only when such intemperance has occurred outside the sacred precincts of matrimony that the public voice has been raised in disapproval. Two

persons legally united are free to injure each other and their offspring as much as they may have a mind to, and it is all right. The legal union covers a multitude of sins. A woman may be invalided for life, may be sent to a lunatic asylum—it is all right. A man may be sexually lower than the most degenerate brute, and yet be all right in the eyes of the public so long as this intemperance is exercised within the pale of holy matrimony. Ignorance is at the root of this evil. Education, as in all other reforms, will alone remedy the evil. Until men and women fully realize the physiological function which they are violating continually, no remedy can be expected. Prohibition, as in all other reforms, will fail. People must be taught that it is a function for the propagation of species alone, and not for pleasure. It is like digestion, a process by which the physical body is supplied with food, which renders it capable of performing its various functions, and not only one by which the palate is tickled and the person pleased. A certain amount of satisfaction must attend these functions, but they were not created for this pleasure alone. A meal under pleasant circumstances is more beneficial than under those that are disagreeable; a sexual union under an atmosphere of love is more beneficial than one under compulsion; but the end of neither is pleasure. Ignorance is at the root of this evil. Two persons utterly devoid of any knowledge of this physical function are united in marriage. Why ignorant? Because knowledge is immodest? Nay, rather, is not such ignorance vulgar? Does it not lead to lower, degenerate, brutish types of humanity? These persons oftentimes having no intellectual or spiritual affinity—for few marriages are sanctioned by the High Courts of Heaven, mercenary plans too often interfere for that—have only a physical affinity, and in the abuse of this function seek that enjoyment which higher sources should provide. Persons satisfied in their intellectual and spiritual life are too free to be slaves to the abuse of a physical function.

This sexual function is one which ought, like all other functions, to be performed in accordance with natural laws. Abnormally exercised, it calls for more and more, and ignorant persons credit this insatiable desire to the strong love of the individuals. As well say that an abnormal stomach, which ever and ever craves for more food, while unable to digest that which it has already received, is a sign of love.

The abuse of this function is one surrounded by so much delicacy that thus far physicians have failed to attack it. They have neglected to look at it from a philosophical standpoint. A certain sacredness—false, though, as it has not striven for the best use of it—has surrounded it. The result of sexual union is sacred in that it embodies the God in man and is full of promise for the future, but the act itself is only a physical one. This sacredness has not been guarded as it ought to have been, for, if this act is carried out under the evils of intemperance, how can the result be perfect? In lower

animal life this function is regularly carried out according to law. Man is the only male who abuses himself and his female. He knows no law in this respect but the dictates of an ignorant desire. If in the lower animals there is a time for sexual union, why not so with man? The physiology of the female generative organs points to such an observance of law. The pregnant woman is, under normal circumstances, incapable of fully engaging in the normal act. She has ovaries which are not functionally active, a uterus which is fully occupied with nourishing and housing the fœtus and sealed to invasion by male germs. Why compel her to engage in that for which her organs are not in a state to reciprocate? Then, after the delivery of her offspring, these organs are still in a state of rest until that offspring is capable of subsisting on other than mother's food. No clearer proof need be advanced than these signs of Nature's desire for sexual rest during this period. What need of the often-asked question, Should intercourse be discontinued during pregnancy? Nature answers it. It is only human selfishness which makes such a question possible.

By observance of this law there will be fewer invalidated women. Women who say "I have not known a day's health since I was married," fewer inmates for asylums, fewer deformed children, and, on the other side, fewer weak-willed men. As the physical nature is made to obey its laws, it will be healthier, and from its more perfect condition will arise stronger intellectuality and spirituality. The population, instead of decreasing, will increase. Women with healthy bodies will not dread maternity. No longer slaves to an abnormal appetite, they will look on this physical function, as they do on those of eating and walking, as a necessary part of their lives. The physician will no longer be implored to put the stamp of Cain on his brow in order to deliver them from a burden which they are unfitted by a misuse of this function to bear. This desire to rid herself of this function of propagating her species has had most direful effects on woman's nature. It has made her cruel and cunning. Woman has ever sought to defy man's oppressive power by cunning, and as long as she is oppressed she will. Women who would be horrified at a murder are willing to murder that little life within them, pleading that the being is not yet alive. Not woman alone, but man also. A woman will come to a physician, desiring to be relieved of her undesired offspring, with the oft-repeated remark: "My husband does not want me to have any more children." Yes, but that selfish husband has not will power to properly recognize that he is misusing a function. Families can be regulated by an exercise of will and reason. The world to-day is full of those who are trying to regulate family, not by an observance of natural law, but rather by artificial means which are sources of danger. A function can only be regulated by an adherence to the law which governs it. Knowledge alone will be the remedy for this evil, which should be called nothing less than legal prostitution.

Therapeutical Notes.

Huchard's Pills for Hæmoptysis.—The *Presse médicale* for November 21st gives the following formula as particularly recommended by Hecht in the treatment of recurrent hæmoptysis:

R Ergotine..... } each .30 grains;
 Quinine sulphate..... }
 Powdered digitalis leaves } each . 3 grains.
 Extract of hyoscyamus. }

M. Divide into twenty pills. From five to ten to be taken daily.

Naphthalene in Puerperal Endometritis.—Kirsner, of Astrachan (*Semaine médicale*, 1900, No. 28: *Fortschritte der Medicin*, November 28th), disinfests the vagina and the cervix uteri, and then packs the uterine cavity with strips of gauze moistened with a ten-per-cent. solution of ichthyol in glycerin and thickly dusted with finely powdered naphthalene. The patient must absolutely remain in bed so long as the tampon is in the uterus. He recommends also the internal use of ergotine. At the end of from six to twelve hours the tampon is removed, and in a few hours more the temperature will generally be found to have fallen; if not, the packing is to be repeated. The treatment is useless if general infection has occurred.

Capsules for Influenza with High Fever and Nervous Symptoms.—The *Indépendance médicale* for November 21st attributes the following formula to Bacelli:

R Quinine salicylate. 3 grains;
 Phenacetine. 2 "
 Camphor. ¼ grain.

M. Make twelve such capsules. From two to six to be taken in twenty-four hours.

An Antiseptic Mixture.—The *Journal des praticiens* for November 28th gives the following formula as emanating from Lacombe and Mercier:

R Sulphuric ether. 400 parts;
 Acetic ether. 150 "
 Alcohol. 300 "
 Salol. 50 "
 Crystallized carbolic acid. 15 "
 Oil of lavender. } each . 25 "
 Oil of wintergreen. }

M.

For Neuralgic Dysmenorrhœa.—The following prescriptions were much used by the late Dr. Alfred Meadows:

R Powdered opium. ½ a grain;
 Extract of cannabis indica. 1 grain;
 Camphor. 2 grains.

To make one pill. (For the opium, two grains of extract of conium may be substituted.) One pill to be taken at bedtime.

Or this, when the dysmenorrhœa is habitual:

R Sulphuric ether. 2 drachms;
 Deodorized tincture of opium. . . 45 minims;
 Tincture of hyoscyamus. 3 drachms;
 Chloral hydrate. 1 drachm;
 Spirits of chloroform. 2 drachms;
 Water. to 6 ounces.

M.

Half an ounce may be taken every two hours.

NEW YORK, SATURDAY, JANUARY 5, 1901.

THE BACTERIAL SELF-PURIFICATION OF STREAMS.

(First Article.)

DURING the construction of the Illinois and Michigan Canal, and especially when it was approaching completion and the sewage of Chicago was to be turned into the Mississippi River, many of the people of St. Louis, it will be remembered, were in a state of dread lest their drinking-water, drawn from the Mississippi, should be dangerously contaminated as the result. The flow has now been going on for some months, however, and the alarm appears to have been needless. Given sufficient time and sufficient distance, and flowing water, even water flowing sluggishly, will free itself from pathogenic bacteria. It is of no little importance to know what agencies are at work in any given instance to bring about this spontaneous self-purification. Instructive studies of the waters of various European rivers, such as the Spree, the Pregel, the Danube, the Limmat, the Isar, the Rhine, and the Seine, have been published from time to time during the last few years, and some work in the same direction has been done in this country. The most recent and one of the most notable of American investigations of this sort has been conducted by Edwin Oakes Jordan, Ph. D., of the bacteriological laboratory of the University of Chicago, who contributes a condensed account of his observations to the December number of the *Journal of Experimental Medicine*.

Dr. Jordan summarizes a number of the best-known European investigations, but points out that, while their general purport points unmistakably to a lessening of the bacterial contents of the water, whether it is due to dilution, to sedimentation, or to the action of sunlight, great differences exist in the degree of apparent purification, depending upon the amount of initial pollution, the velocity of the flow, the season of the year, and other elements. Each stream, he remarks, seems to have its own condi-

tions, and conclusions drawn from an examination of any one cannot be applied to another; each stream must be subjected to detailed special observation. His own work, though nominally limited to the Illinois River and its tributaries, really included observations at various points, ending as far away from Chicago as at Chain of Rocks, on the Mississippi, whence the St. Louis water supply is obtained. The results are recorded largely in tabular form. The tables, thirty-eight in number, give each the results of a series of examinations for each locality, in most instances between twenty-five and thirty, made a few days apart during the period from May to December.

At Bridgeport, on the canal itself, the number of bacterial colonies in a cubic centimetre of water, ranged from 225,000 to 1,850,000; at Lockport, also on the canal, from 40,000 to 1,650,000; at the same place, but in water from the Desplaines River, from 1,250 to 34,000; above Joliet, in the same river, from 20,000 to 1,620,000; below Joliet, from 120,000 to 2,540,000; at Wilmington, in the water of the Kankakee River, from 1,400 to 25,700; at Morris, in the water of the Illinois River, from 16,000 to 1,140,000; at Ottawa, in the water of the Fox River, from 450 to 34,500; above Ottawa, in the water of the Illinois River, from 650 to 130,000; at La Salle, in the water of the Big Vermilion River, from 1,400 to 62,000; at the same place, in the water of the Illinois River, from 700 to 228,000; at the same place, in the water of the canal, from 16,000 to 152,000; at Henry, in the water of the Illinois River, from 500 to 74,000; at Averyville, in the water of the same river, from 500 to 19,500; at Wesley City, in the water of the same river, from 5,000 to 3,390,000; at Pekin, in the water of the same river, from 5,000 to 2,030,000; at Havana, in the water of the same river, from 850 to 128,000; at Chandlerville, in the water of the Sangamon River, from 1,200 to 11,600; at Beardstown, in the water of the Illinois River, from 1,500 to 120,000; at Kampsville, in the water of the same river, from 340 to 23,500; at Grafton, in the water of the same river, from 180 to 97,000; at the same place, in the water of the Mississippi River, from 800 to 45,000; at Alton, in the water near the eastern bank of the Mississippi, from 900 to 39,000; at the same place, in the water east of the middle of the river, from 900 to 40,400; at the same place, in midstream water, from 700 to 27,500; at the same place, west of the middle of the river, from 700 to 25,500; at the same place, near the western bank of the river, from 650 to 37,500; at West Alton, in the water of the Missouri River, from 2,100 to 20,900; at Chain of Rocks, in the water of the

Mississippi (eastern bank), from 1,300 to 113,000; at the same place (midstream), from 1,600 to 68,000; at the same place, at the inlet tower of the St. Louis water works, from 1,800 to 69,000; at the same place (western bank), from 2,700 to 57,500; at St. Louis (tap water), from 340 to 2,790; at Jefferson Barracks, in water near the eastern bank of the Mississippi, from 1,000 to 69,000; at the same place, in the water east of the middle of the river, from 1,700 to 42,000; at the same place (midstream), from 2,700 to 56,500; at the same place, in water to the west of the middle of the river, from 3,200 to 91,600; at the same place, in water near the western bank, from 4,900 to 65,300.

It is estimated that eighty-five per cent. of the sewage of Chicago is carried into the Illinois River. Dr. Jordan gives the following averages of the numbers of bacterial colonies found at various points on the canal, the Desplaines River, and the Illinois River: Bridgeport (practically Chicago), 1,245,000; Lockport (29 miles away), 650,000; Joliet (33 miles away), 486,000; Morris (57 miles away), 439,000; Ottawa (81 miles away), 27,400; La Salle (95 miles away), 16,300; Henry (123 miles away), 11,200; Averyville (159 miles away), 3,660; Wesley City (165 miles away), 758,000; Pekin (175 miles away), 492,600; Havana (199 miles away), 16,800; Beardstown (231 miles away), 14,000; Kampsville (288 miles away), 4,800; Grafton (318 miles away), 10,200. Dr. Jordan's comments on these figures, and his very interesting remarks on the subject in general, we shall refer to in another article.

RECOVERY FROM ACUTE HYDROCEPHALUS.

IN an example of this extremely rare occurrence recently reported to the Berlin Society of Internal Medicine by Neumann (*Deutsche Medizinal-Zeitung*, November 12th) the disease was interpreted as a syphilitic manifestation. The patient, a child seventeen months old, was shown at the meeting. It had come under Neumann's treatment when it was five months old, at which time the head had become very large and the mother feared that it contained water. The history given then was that when the child was between two and three months old it had suffered with a cutaneous eruption, and manifestly it had had antisiphilitic treatment. It still had the yellowish-gray tint of skin characteristic of infantile hereditary syphilis. The hydrocephalus was typically developed; the circumference of the head was

forty-seven centimetres, the forehead bulged decidedly, the fontanelle was gaping, and the child was backward in mental development.

Syphilis being assumed to be the cause of the disease, treatment with potassium iodide was begun, and the result was astonishing. In so short a time as thirteen days the circumference of the head had decreased by several centimetres, the widened sutures had closed, and the anterior fontanelle, previously prominent, was so sunken that the edges of the surrounding bones stood out, not having been able to recover their proper form fast enough to keep pace with the diminution of the cranial contents. The improvement advanced steadily; the vault of the skull became firm, the fontanelle grew smaller, and the child acquired the mental development proper to its age, being sprightly and cheerful. It began to talk when it was eleven months old, and the teeth made their appearance in due number; at that time there were already two canine teeth.

A syphilitic disease of the eyes accompanied the hydrocephalus; the retina was clouded with white and the pupil was hazy. This affection, too, improved *pari passu* with the hydrocephalus, so that at the time the child was shown only a few little white spots remained on the fundus. Four grains of potassium iodide had been given daily, and a number of inunctions of fifteen grains of mercurial ointment had been employed. Evidently this case may be looked upon as a striking example of the enhanced susceptibility of cure shown by the gravest affections of the central nervous system when they owe their existence to syphilis.

THE NOXIOUSNESS OF THE EUROPEAN PLANE-TREE.

THAT species of the sycamore family of trees which is found in southern Europe and middle Asia, the *Platanus orientalis*, or *Platanus palmata*, of the botanists, has been used topically as a medicament, the flowers for venomous bites, for hæmorrhage, and as a vulnerary, and the leaves and bark as a discutient. Whatever may be the value of the tree in medicine, it appears that it has certain noxious properties and harbors a parasitic acaride which sometimes attacks man. At least, Dr. Stéphen Artault (*Archives de parasitologie*, 1900, p. 115; *Gazette hebdomadaire de médecine et de chirurgie*, December 9th), writing of the *platane* of France, which we presume is the tree in question, states that it is the source of dust-like particles which are irritating to the nose, the eyes, and the bronchial tubes. It proceeds from the fruits and especially from the down on the lower surface of the

leaves. The tuft of the achæmium, too, consists of long, stiff hairs, and they are charged with a sort of pulverulent resin and may be irritating, though certainly much less so than the hairs which cover the buds, the flowers, and the lower surface of the young leaves.

Besides its own irritating properties, the tree occasionally proves a pest by reason of its harboring a certain acaride, the *Tetranychus telarius*, which acts as a cutaneous irritant. Toward the close of winter it is easy to expose numerous nests of these insects by detaching the cortical scales of the trunk and branches of the tree. Their bite is not severe. It produces a little papule and gives rise to itching, which, however, lasts for only about fifteen minutes. Later in the season, when the buds have opened, the acarides migrate and may be found scattered over the lower surface of the leaves. Moreover, they leave the tree in spring and attack certain garden plants, on which they pass the entire summer. This occurs in the country; in Paris the parasites cannot exist elsewhere than on the tree, and they go into winter quarters earlier than their rural congeners. Their season of activity is much curtailed, lasting only three or four months, whereas the country *Tetranychus* flourishes for more than seven months. It is supposed to be in consequence of this fact that the Parisian insect is smaller than the country specimens, and its prolonged deprivation of food is thought to account for its attacking man more commonly at the close of winter than at other times.

THE PHILADELPHIA MEDICAL JOURNAL.

WE learn that, except as to the original articles to be published in the January 5th number, Dr. George M. Gould's editorial responsibility has ceased. We learn also that there is some talk of establishing a new journal in Philadelphia, with Dr. Gould as its editor. He writes to us: "I am urged on all sides to start a new journal. Will do so if the profession wishes and will help." He asks to be addressed at No. 1631 Locust Street, Philadelphia.

AN UNCALLED-FOR ASPERSION.

WE hear much of the bad taste of journalism on this side of the Atlantic, but we trust that it will be a long time before any American medical journal will emulate the course pursued by a leading English medical journal in its issue for December 1st. In commenting upon the letter of a correspondent who takes exception to the paper's statement that "there is no such thing as a qualified homœopathic medical man," it sustains its proposition by the argument that (in England) a physician who professes to be a homœopath, has his place upon the *Medical Register*, not by virtue of any homœopathic

work, but in consequence of having gone through the regular course and obtained regular qualifications, the same as those held by all other practitioners. It then proceeds, in illustration of its meaning, to cite as analogous the case of a once famous politician, now dead, who, it says, "was a patriot according to his convictions, the idol of his followers, and the paramour of" a certain lady, also dead, we believe, whose name is mentioned. "But," continues this journal, "he was not the idol of his followers because he was the paramour of Mrs.—; and homœopaths are not on the *Medical Register* because of their therapeutic views."

Even had the case in point—a *cause célèbre* of some years ago—been the only available analogy to point the journal's moral and adorn its tale, its introduction would have been a cruel act; but, since countless others were available, it is uncalled-for defilement of the memory of the dead.

THE HIPPOCRATIC STIPULATION AGAINST "CUTTING FOR STONE."

As is well known, the Hippocratic oath contains among other things an undertaking not to "cut for stone." According to the *Indian Medical Record* for November 17th, Dr. Charpington, who has written a monograph upon the subject, thinks that Hippocrates referred to castration, and not to cutting for stone. The *Record* says: "Considering the licentiousness reigning at that time, and the fact that pæderasty was prevalent, slaves and others being castrated that they might grow up emasculated and therefore more feminine in actions and appearance, it is probable that castration was the operation interdicted by the oath."

The fact that this injunction is coupled with a pledge not to give an abortifacient to a woman, adds some color to this view.

THE CHICAGO PENNY LUNCH-ROOMS.

AN excellent institution in the shape of a penny lunch-room has been established under the auspices of the St. Luke's Society, in Chicago. Every article on the bill of fare is priced at one cent. This bill includes coffee with sugar and milk, doughnuts, Wienerwurst, rolls, soup, mush and milk, etc. Three cents will suffice to secure a substantial breakfast, it is said, and five cents a day will certainly keep a man far removed from starvation. So successful from a financial point of view has the scheme proved, that it is contemplated to establish nineteen other such rooms in different parts of the city. Any man or woman, almost even any child, who is willing to work, can surely earn, even in the worst times, a nickel a day at "odd jobs," so that deaths from actual starvation should henceforth become impossible in Chicago. This scheme will, moreover, afford an excellent and practical method to charitably disposed persons of limited means, who, while compelled to refuse alms in indiscriminate charity, often find their hearts aching as

they read of deaths from starvation in the paper, and call to mind the poor unfortunate who "looked genuine" the other day when they were compelled to turn a deaf ear to his appeals. We would suggest to the society that checks or tickets should be purchasable, redeemable at any of the lunch-rooms, and the poorest could then carry "the price of a meal" in his pocket to give to any seemingly deserving one without fear of being seriously imposed upon, or of being taxed beyond his capacity. We wish every success to Chicago's enterprise, and should be glad to see its initiative followed here in New York.

A NASAL DISEASE OF DOUBTFUL NATURE.

At a recent meeting of the Lyons Society of the Medical Sciences (*Gazette hebdomadaire de médecine et de chirurgie*, November 15th), Berchoud showed a man with a violet-colored tumefaction of the lower part of the nose of such uncertain nature that three different diagnoses were made, that of a neoplasm, that of rhinoscleroma, and that of syphilis. The man had given a history of having had syphilitic manifestations many years before, and his trouble had been mitigated by subcutaneous injections of mercury biniodide.

INVASION OF THE LABIUM MAJUS BY A FEMORAL HERNIA.

A VERY rare form of hernia is the femoral invading the territory of the inguinal. An example of it has lately been reported by Stieda (*Deutsche Zeitschrift für Chirurgie*, lvi; *Centralblatt für Chirurgie*, December 8th). The hernia was a femoral epiplocele, occurring in a woman fifty-four years old, which suddenly became enlarged and strangulated, and a portion of it was found to have been forced into the labium majus, apparently through a lacuna in the cribriform fascia.

THE ACTION OF SUNLIGHT ON THE TUBERCLE BACILLUS.

At a recent meeting of the Paris Society of Biology (*Gazette hebdomadaire de médecine et de chirurgie*, November 1st) Jausset reported on a number of experiments on guinea-pigs. Sputa containing Koch's bacillus were exposed to direct sunlight and to diffused light, and then used in the experiments. In a considerable number of cases the sputa were found to have been completely sterilized, and the guinea-pigs inoculated with them were not injured; those that were infected survived for a long time and gained in weight, and the bacillus was found only at the site of the inoculation. It has not yet been ascertained how long an exposure to sunlight is required to render tuberculous sputa absolutely innocuous.

News Items.

Society Meetings for the Coming Week:

MONDAY, January 7th: New York Academy of Sciences (Section in Biology); German Medical Society of the City of New York; Morrisania Medical Society, New York (private); Brooklyn Anatomical and Surgical Society (private); Corning, New York, Academy of Medicine; Utica, New York, Medical Library Association; Boston Society for Medical Observation; St. Albans, Vermont, Medical Association; Providence, Rhode Island, Medical Association; Hartford, Connecticut, Medical Society; South Pittsburg, Pennsylvania, Medical Society; Chicago Medical Society.

TUESDAY, January 8th: New York Academy of Medicine (Section in Genito-urinary Surgery); New York Medical Union (private) (election); New York Obstetrical Society (private); Buffalo Academy of Medicine (Section in Medicine); Kings County, New York, Medical Association; Medical Societies of the Counties of Chango (quarterly—Binghamton), Clinton (annual—Plattsburgh), Erie (annual—Buffalo), Genesee (semi-annual—Batavia); Greene (quarterly), Jefferson (annual—Watertown), Madison (semi-annual), Oneida (quarterly—Utica), Ontario (quarterly), Rensselaer (quarterly), Schenectady (annual—Schenectady), Schuyler (annual), Steuben (semi-annual), Tioga (annual—Owego), Wayne (semi-annual), and Yates (semi-annual), New York; Newark, New Jersey, Medical Association (private) (election); Trenton, New Jersey, Medical Association; Clinical Society of the Elizabeth, New Jersey, General Hospital and Dispensary; Northwestern Medical Society of Philadelphia; Practitioner's Club, Richmond, Kentucky; Richmond, Virginia, Academy of Medicine and Surgery.

WEDNESDAY, January 9th: New York Pathological Society (annual); New York Surgical Society; American Microscopical Society of the City of New York; Society of the Alumni of the City (Charity) Hospital; Society for Medical Progress; Medical Societies of the Counties of Albany, Dutchess (annual—Poughkeepsie), and Seneca (semi-annual), New York; Tri-States Medical Association (Port Jervis), New York; Pittsfield, Massachusetts, Medical Association (private); Hampshire, Massachusetts, District Medical Society (quarterly—Northampton); Worcester, Massachusetts, District Medical Society (Worcester); Bennington, Vermont, and Hoosick, New York, Medical Society (annual—Arlington); Kansas City Missouri, Ophthalmological and Otological Society; Philadelphia County Medical Society.

THURSDAY, January 10th: Society of Medical Jurisprudence and State Medicine, New York; Brooklyn Pathological Society (annual and election); Medical Societies of the Counties of Cayuga and Fulton (annual—Johnstown), New York; South Boston, Massachusetts, Medical Club (private); Pathological Society of Philadelphia.

FRIDAY, January 11th: New York Academy of Medicine (Section in Neurology); Yorkville Medical Association, New York (private); Brooklyn Dermatological and Genito-urinary Society (private); German Medical Society of Brooklyn; Medical Society of the Town of Saugerties, New York.

SATURDAY, January 12th: Obstetrical Society of Boston (private); Worcester, Massachusetts, North District Medical Society.

Marine-Hospital Service:

Official List of the Changes of Station and Duties of Commissioned and Non-commissioned Officers of the United States Marine Hospital Service for the Seven Days ending December 27, 1900:

BAHRENBURG, L. P. H., Assistant Surgeon. Relieved from duty at the Immigration Depot, New York, and directed to proceed to Manila, Philippine Islands, and report to the chief quarantine officer for duty.

DECKER, C. E., Assistant Surgeon. Granted leave of absence for fourteen days on account of sickness.

DUFFY, FRANCIS, Acting Assistant Surgeon. Granted leave of absence for six days from December 29th.

LINLEY, W. J., Acting Assistant Surgeon. Granted leave of absence for thirty days.

MCINTOSH, W. P., Surgeon. To proceed to Columbus, Georgia, for special temporary duty.

Marine-Hospital Service Health Reports:

The following cases of small-pox, yellow fever, cholera and plague, were reported to the surgeon-general during the week ending December 28, 1900:

Smallpox—United States.

Jacksonville, Florida.....	Dec. 22.....	1 case.	
Wichita, Kansas.....	Dec. 15-22.....	10 cases.	
Lexington, Kentucky.....	Dec. 22.....	1 case.	
Baltimore, Maryland.....	Dec. 22.....	1 case.	
Minneapolis, Minnesota.....	Dec. 15-22.....	12 cases.	
Winona, Minnesota.....	Dec. 15-22.....	120 cases.	
Manchester, New Hampshire.....	Dec. 15-22.....	14 cases.	
Jersey City, New Jersey.....	Dec. 16-23.....	7 cases.	
New York City, New York.....	Dec. 15-22.....	21 cases.	
Ashtabula, Ohio.....	Dec. 15-22.....	15 cases.	
Cleveland, Ohio.....	Dec. 15-22.....	25 cases.	
Portsmouth, Ohio.....	Dec. 22.....	1 case.	
Memphis, Tennessee.....	Dec. 22.....	1 case.	
Houston, Texas.....	Dec. 15-22.....	22 cases.	1 death.
Salt Lake City, Utah.....	Dec. 15-22.....	31 cases.	
Tacoma, Washington.....	Dec. 15.....	1 case.	
Milwaukee, Wisconsin.....	Dec. 22.....	1 case.	

Smallpox—Foreign.

Buenos Ayres, Argentina.....	Sept. 30.....	7 cases.	6 deaths.
Prague, Bohemia.....	Nov. 24-Dec. 1.....	43 cases.	
Pernambuco, Brazil.....	Oct. 1-15.....		26 deaths.
Rio de Janeiro, Brazil.....	Oct. 1-31.....		69 deaths.
Alexandria, Egypt.....	Nov. 27.....	3 cases.	1 death.
London, England.....	Dec. 1-8.....	1 case.	
Paris, France.....	Dec. 1-8.....		14 deaths.
Calcutta, India.....	Nov. 17.....		6 deaths.
Mexico, Mexico.....	Dec. 16.....	1 case.	2 deaths.
Progreso, Mexico.....	Dec. 9-15.....	3 cases.	
St. Petersburg, Russia.....	Nov. 24-Dec. 1.....	9 cases.	
Warsaw, Russia.....	Nov. 24-Dec. 1.....		36 deaths.
Glasgow, Scotland.....	Dec. 7-14.....	58 cases.	1 death.

Yellow Fever.

Rio de Janeiro, Brazil.....	Oct. 1-31.....	31 cases.	6 deaths.
Vera Cruz, Mexico.....	Dec. 14.....		2 deaths.

Cholera.

Bombay, India.....	Nov. 13-20.....		3 deaths.
Calcutta, India.....	Nov. 10-17.....		26 deaths.
Madras, India.....	Nov. 9-16.....		7 deaths.
Singapore, Straits Settlements.....	Nov. 10-13.....	5 cases.	5 deaths.

Plague.

Petropolis, Brazil.....	Dec. 10.....		1 death.
Rio de Janeiro, Brazil.....	Oct. 1-31.....	21 cases.	20 deaths.
Calcutta, India.....	Nov. 17.....		2 deaths.
Osaka, Japan.....	Nov. 2-27.....	8 cases.	8 deaths.
Tamatave, Madagascar.....	Nov. 11.....	1 case.	

Infectious Diseases in New York:

We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported for the two weeks ending December 29, 1900:

DISEASES.	Week end'g Dec. 22		Week end'g Dec. 29	
	Cases.	Deaths.	Cases.	Deaths.
Typhoid fever.....	57	0	87	19
Scarlet fever.....	0	22	191	4
Cerebro-spinal meningitis.....	0	7	0	0
Measles.....	90	5	99	0
Diphtheria.....	171	48	271	33
Small-pox.....	21	0	11	2
Tuberculosis.....	168	142	199	156
Varicella.....	68	0	0	0
Laryngeal diphtheria (croup).....	10	15	15	8

Small-pox.—The local small-pox scare in New York City has caused the number of vaccinations performed to break all previous records. Eight cases of small-pox have been discovered in Brooklyn, and from one to four new cases come to light daily in Manhattan Borough. One hundred and fifty physicians have been employed by the city board of health to vaccinate applicants free of charge, and it is estimated that over three thousand have already been vaccinated. The Board of Health of the State of New York has issued a special circular of warning. The reports of outbreaks of small-pox appear at different points all over the United States, including the following: Schenectady, N. Y.; Greenup, Ky.; Cecil, near Toledo, Ohio; Gates Mills, near Cleveland, Ohio, and at

various points in Wisconsin, Missouri, Minnesota, Colorado, Michigan, and in Washington, D. C. One salutary effect produced by the outbreak is the vast increase that has taken place in the number of persons vaccinated.

To Succeed Dr. Hunter McGuire.—Dr. J. Allison Hodges, formerly of North Carolina, and for several years past Professor of Nervous Diseases in the University College of Medicine, Richmond, Va., has been elected to the presidency of the college, to succeed the late Dr. Hunter McGuire. Dr. Hodges has held successively the offices of corresponding secretary, proctor, and dean of the institution.

A Change of Editorship in the Northwestern Lancet.—Dr. Alexander J. Stone has retired from the editorship of the *Northwestern Lancet*, his successor being Dr. W. A. Jones.

Medical Society of City Hospital Alumni, St. Louis.—At the last regular meeting, on Thursday evening, the 3d inst., Dr. H. W. Soper reported cases of infectious disease of the kidney.

The New York Academy of Medicine.—At the last stated meeting, on Thursday, January 3d, the order for the evening was as follows: Address of the retiring president, by Dr. William H. Thomson; the Inaugural Address, by Dr. Robert F. Weir; Memorial Address on the Life of Dr. Lewis Albert Sayre, by Dr. Leroy M. Yale; presentation of a portrait of the late Dr. John Hoskins Griscom, original fellow and vice-president of the Academy in 1854; and the reading of the annual reports of officers and committees.

At the next meeting of the Section in Otology, on Wednesday evening, the 9th inst., Dr. J. A. Kenefick will read a paper entitled *The Use of Electrolysis in the Destruction of Organized Stricture of the Eustachian Tube*. Cases will be presented and specimens and new instruments will be exhibited.

At the next meeting of the Section in Pædiatrics, on Thursday evening, the 10th inst., a memorial address on the late Dr. J. Henry Fruitnight will be read, and Dr. H. Illoway will present a paper on *Infantile Colic and Colic in Infants*. Cases will be reported by Dr. Thomas S. Southworth and Dr. Vanderpoel Adriance.

Reopening of New Jersey Hospitals.—The General Hospital and Dispensary and the Blake Memorial Hospital for Women, both at Elizabeth, N. J., which had been closed in consequence of an outbreak of diphtheria, were reopened on December 15th.

Dr. Knapp's Gift to the New York Ophthalmic and Aural Institute.—This institution, which has been in existence since 1869, was on January 2d presented by Dr. Herman Knapp with the freehold of the buildings at present occupied by it, namely, Nos. 44 and 46 East Twelfth Street, on the south side of the street, a little over a hundred feet west of Broadway. The two buildings have been remodeled to serve the needs of the institution.

The Iowa Central State Medical Society held its seventh annual meeting in Marshalltown on December 11th. The following programme was announced: President's address, by Dr. W. E. Whitney, of Eldora; Appendicitis—Report of Cases, by Dr. F. S. Smith, of Nevada; Kidney and Gall Stones, by Dr. A. D. Bevan, Rush Medical College; Empyema, by Dr. M. U. Chesire, of Marshalltown; Sanitary Engineering in Small Cities (including a discussion of Sewage Disposal), by A. Marston, Assoc.

M. Am. Soc. C. E., professor of civil engineering Iowa State College of Agriculture and Mechanic Arts; Castration for Senile Hypertrophy of Prostate Gland, with Report of Case, by Dr. A. M. Sherman; voluntary papers and presentation of cases by Dr. N. E. Mighell, of Marshalltown, and others.

Fortieth Anniversary of the German Medical Society of New York.—The members of the German Medical Society of New York recently assembled in the Arion Club to celebrate its fortieth anniversary by a dinner. Dr. C. A. von Randohr, the toastmaster, delivered the opening address. Following him came a toast by Dr. H. Klotz, the retiring president, and Dr. George Jacobi, the new president, also spoke. Further speeches were made by Dr. F. Lange, Dr. A. Rose, and Dr. S. Breitenfeld.

Annual Meeting of the Rochester Academy of Medicine.—The first annual meeting of the Rochester Academy of Medicine was held recently. Officers for the ensuing year were elected as follows: President, Dr. William S. Ely; vice-presidents, Dr. Charles A. Dewey, Dr. John O. Roe, Dr. Simon L. Elmer and Dr. Richard M. Moore; secretary, Dr. Henry T. William; treasurer, Dr. Edward B. Angell; members of the council, Dr. Eugene H. Howard and Dr. Edward Mulligan; library committee, Dr. J. O. Roc, Dr. J. Livingston Roseboom and Dr. E. B. Angell.

Trustees of a Medical College Resign.—Dr. S. M. Monser, Dr. J. R. Laine, and Dr. Samuel Potter have resigned from the board of trustees of the College of Physicians and Surgeons at San Francisco, of which Dr. Winslow Anderson is president, on the ground that diplomas are too easily obtained. Several members of the faculty have also resigned, including Dr. E. E. Kelley, Professor of Anatomy.

New Officers of the Minnesota Valley Medical Association.—At the twentieth annual meeting of the Minnesota Valley Medical Association, held recently at Mankato, Minn., the following officers were elected: President, Dr. O. H. McMichael, of Vernon Center; first vice-president, Dr. W. S. Fullerton, of Minnesota Lake; second vice-president, Dr. G. W. McCarthy, of Madelia; third vice-president, Dr. J. W. Daniels, of St. Peter; treasurer, Dr. G. F. Merritt, of St. Peter; secretary, Dr. E. D. Steel, of Mankato.

The South Texas Medical Association held a meeting at Houston, Texas, recently and many important papers were read. A banquet was given after the meeting adjourned. The president of the association is Dr. J. H. Reuss, of Cuero; Dr. R. T. Morris, of Houston, is first vice-president; Dr. John T. Moore, of Galveston, second vice-president, and Dr. D. S. Wier, of Houston, secretary and treasurer.

The Bellevue Hospital Investigation.—Louis H. Hilliard, a patient in the insane pavilion at Bellevue Hospital, died recently under circumstances calling for an investigation. The coroner's jury which sat on the case found that he came to his death through violence, and three male nurses have been held under bonds to answer criminal charges in connection with his death. This institution being within the department of charities of the city of New York, the commissioner of charities, Mr. John W. Keller, has instituted an investigation into the alleged abuses in the treatment of the insane patients who

pass through Bellevue; and this investigation is still in progress. As a result of the investigation ten undergraduate male nurses have been discharged, Dr. L. W. Schultze has been placed in charge of the pavilion, and several changes have been made in the rules governing the commitment of the insane. Under a former rule the examiners in lunacy were permitted to make a charge of \$25 when the patient had means, but this has now been abolished. Many sensational stories of maltreatment of the insane in the hospital have come to the surface during the newspaper agitation, and considerable feeling has been developed by statements appearing in the daily papers as emanating from Commissioner Keller. In some of these statements the responsibility for the conditions existing at Bellevue Hospital has been placed by implication on the medical board of the institution, and some of the members of that board deny the imputation that they have been remiss in the discharge of their duties, and say that "practical politics" is to blame for a lack of proper organization and discipline in the institution. Other members of the board emphatically deny that party politics is a factor in the trouble, and warmly champion Commissioner Keller's administration. It is intimated that the State board of charities may institute an investigation of the hospital. The members of the medical board of Bellevue are: Consulting Physicians and Surgeons: Dr. F. Delafield, Dr. S. Smith, Dr. E. L. Keyes, Dr. Austin Flint, Dr. R. F. Weir, Dr. C. A. Leale, Dr. G. W. S. Gouley, Dr. L. A. Stimson, Dr. A. Jacobi.

Visiting Physicians and Surgeons: Dr. W. M. Polk, Dr. A. A. Smith, Dr. W. Gill Wylie, Dr. C. L. Dana, Dr. G. B. Fowler, Dr. H. P. Loomis, Dr. H. M. Diggs, Dr. W. B. James, Dr. A. Lambert, Dr. W. G. Thompson, Dr. A. Flint, Jr., Dr. F. W. Jackson, Dr. J. W. Brannan, Dr. Charles E. Nammack, Dr. Egbert Le Fevre, Dr. Charles Phelps, Dr. W. F. Fluhrer, Dr. J. D. Bryant, Dr. F. S. Dennis, Dr. S. Alexander, Dr. B. B. Gallaudet, Dr. George Woolsey, Dr. F. W. Gwyer, Dr. R. W. Taylor, Dr. Joseph D. Bissell, Dr. H. C. Coe, Dr. L. Bolton Bangs, Dr. B. Farquhar Curtis, Dr. George D. Stewart, Dr. Charles H. Chetwood, Dr. John B. Walker, Dr. George Lockwood. At a meeting of the medical board, held on January 2d, at which twenty-nine of the members were present, a letter from Commissioner Keller asking for information on certain points relating to the conduct of the medical officers in the hospital was discussed and an answer was drawn up. The reply informs the commissioner that a special committee of five has been appointed to take up the matter of the general conditions in the hospital and bring them to his notice officially, and then proceeds to answer Mr. Keller's questions. The letter says: "So far from the patients being injured by the bedside instruction of students in Bellevue Hospital, they are helped by it, and in the vast majority of cases the patients do not dislike or fear the interest that is shown in them, but rather the contrary. It is the experience of this institution and all others that medical instruction given in connection with the hospital promotes the best interests of the patients and of the hospital." * * * "The medical board has nothing to do with the fee system in the insane pavilion, the medical examiners being paid city officers, not under the control or direction of the medical board in any way, and their functions are not those of the treatment and care of the patients. The same regulations govern the house physician touching the alcoholic ward and pavilion for insane as govern the wards in the main hospital. It is considered proper and right for a nurse to administer hypodermic injections, but solely under the directions of the house or visiting

physician; it is a part of their training as nurses that they should be able to use a hypodermic syringe, but never except under medical directions."

The letter concludes:

"We have, in the foregoing, replied to the questions you have asked us. We are ready to supplement these answers in any way you wish, and to cooperate with you in perfecting the service in any way. The records of the hospital will show that no institution is doing more effective medical and surgical work in the cause of the sick poor than Bellevue Hospital, and the more completely this work is known, the more confident shall we be that the worth and merits of Bellevue Hospital will be recognized."

A letter from Dr. Austin Flint, the president of the board, was presented, the letter explaining the circumstances under which he received a fee from a patient in the insane pavilion at Bellevue. Dr. Flint's letter explained that he had already once examined the patient before his commitment to Bellevue in consequence of having made a public disturbance; that he visited him there, not in any official capacity, but at the request of his family, and to insure his prompt removal to a private asylum, which was effected, on the application of Dr. Flint and his associate to the court. Dr. Flint wrote that the courtesy of allowing members of the medical board to examine private patients in the hospital, so far as he was aware, had never been questioned, except in connection with this case. He appended to his letter a copy of a plan for the reorganization of the insane pavilion, which he drew up and submitted to the head of the department in January, 1898. This plan embraced a concentration of authority in the hands of responsible professional men. Two resident physicians were provided for the insane pavilion, who should already have served on and through the house staff of the hospital, and one of whom should always be on duty. Over them was to be a visiting physician in charge, who should be appointed by the Commissioner of Charities on the nomination of the medical board, and who should have power to suspend summarily, and subject to the approval of the board, any person employed in the pavilion, the suspension of a trained nurse to be reported at once to the institution with which the nurse was connected.

A letter from Dr. Allen Fitch in regard to his connection with the case in which a fee had been charged was received by Dr. Charles L. Dana, president of the board, in which he said that he, at Mrs. Newport's request, examined her husband. Then Dr. Flint prepared the necessary certificate for presentation to the court for Mr. Newport's removal to a private sanitarium, as Mrs. Newport desired. All the proceedings were hurried, at Mrs. Newport's urgent request. "I own no stock in any private asylum, and have never accepted a commission for sending cases to them," wrote Dr. Fitch. He had no knowledge that his name was to be used in Dr. Flint's bill.

Births, Marriages and Deaths.

Born.

BELL.—In Kansas City, Missouri, on Tuesday, December 18, 1900, to Dr. and Mrs. B. F. Bell, a son.

Married.

BOWERS—JENNINGS.—In New York, on Wednesday,

December 19, 1900, Dr. Harry W. Bowers, of Harrisonburg, Virginia, and Miss Ethyll Maude Jennings.

COWAN—DADE.—In Springfield, Missouri, on Tuesday, January 1, Dr. Robert M. Cowan, United States Volunteers, and Miss Agnes Dade.

GARDNER—CHRISTIAN.—In Savannah, Illinois, on Monday, December 10, 1900, Dr. S. Howell Gardner, of Sharpsburg, Maryland, and Miss Harriett Christian.

KNOX—MCCOY.—In Kansas City, on Tuesday, December 11, 1900, Dr. Andrew Christy Knox, of Jopline, Missouri, and Miss Mary E. McCoy.

LYMAN—LONG.—In St. Louis, on Thursday, December 13, 1900, Dr. Henry Lyman and Miss Sarah Long.

MANSFIELD—MORRISSEY.—In Rochester, on Thursday, December 20, 1900, Dr. James E. Mansfield, of Oswego, New York, and Miss May Morrissey.

Died.

ACREE.—In Eddyville, Kentucky, on Sunday, December 23, 1900, Dr. C. E. Acree, aged fifty years.

BROWN.—In New York, on Thursday, December 27, 1900, Dr. Ulysses Higgins Brown, of Syracuse, New York, in the fifty-first year of his age.

BROWNLEE.—In Kansas City, Missouri, on Wednesday, December 19, 1900, Dr. J. C. Brownlee.

COLLINS.—In Varina, Virginia, on Tuesday, December 25, 1900, Dr. W. Samuel Collins.

DENNISON.—In Marion, Illinois, on Sunday, December 23, 1900, Dr. Edward L. Dennison, in the sixty-fifth year of his age.

FERRIS.—In Mount Vernon, New York, on Wednesday, December 26, 1900, Dr. Isaac Ward Ferris, aged sixty years.

GIDDINGS.—In Housatonic, Massachusetts, on Friday, December 28, 1900, Dr. Theodore Giddings, in the sixty-fourth years of his age.

GOODRIDGE.—In Lakewood, New Jersey, on Thursday, December 27, 1900, Dr. John C. Goodridge, of New York.

LOSEE.—In Upper Red Hook, New York, on Saturday, December 22, 1900, Dr. John E. Losee, aged seventy-four years.

MARCY.—In New York, on Thursday, December 28, 1900, Dr. Erastus Edgerton Marcy.

Pith of Current Literature.

Medical Record, December 29, 1900.

Some Remarks on Medicine in 1800. By Dr. George K. Welch.—The beginning of the nineteenth century coincides quite closely with the emergence of the art of medicine from the domination of the so-called "systems." This release of the professional mind from the necessity of constructing or accepting an imaginary theory of medicine, joined to the discovery of means which rendered it no longer necessary to diagnosticate illness merely by the appearance of the patient and his statements, was a great incentive to the noting and recording of facts which served as a basis for further advance. The achromatic microscope, anæsthesia, and the cell theory toward the middle of the century, and later, antiseptics, powerfully aided this advance. An interesting account is given of the last illness of George Washington, quoted from

the *Medical Repository* for 1800. He died from laryngeal diphtheria. The treatment, it would seem, of an old man, sick with a disease very exhausting to vitality, and so severe that the illness lasted but twenty-four hours, consisted in the abstraction of between two and three quarts of blood; the administration of about twenty grains of calomel and six grains of tartar emetic, an injection, with external application of a blister. If we note the contrast between the fanciful and changeable theories of medicine in 1800, and the well-grounded and stable theories of to-day; the practically nonexistent physiology of 1800, and the physiology of to-day; the surgery of 1800, without anæsthesia or antisepsis, and the surgery of to-day; the therapeutics of 1800, including the domination of the lancet, prostrating emetics and cathartics, and the modern treatment; the guesswork diagnosis of 1800, and the scientific investigation of the functions of the body with instruments of precision, and of its organs by many well-adapted means to-day; the wild theories of ætiology prevalent in 1800, with the present steadily lengthening list of the diseases the exciting cause of which is certain—we shall be assured that medicine stands abreast of other arts and sciences in the century's advance.

A Case of Gonorrhœal Endocarditis with Congenital Malformation of Mitral Valves. By Dr. G. W. McCaskey.—There are several points of interest in this case. One of especial interest from a diagnostic viewpoint is the left-sided location of the greatest intensity of a basal murmur, proved by autopsy to have been the result of an aortic lesion. The general statement of the authorities with reference to this question ought to be qualified materially, as there are doubtless many cases in which this anomalous location of the greatest intensity of aortic murmur exists; and unless the exceptional cases are kept well in mind it may lead to errors in diagnosis.

The Operative Treatment of Varicose Veins of the Lower Extremities. By Dr. W. C. Borden.—The author, arguing from the pathological condition of a varicose vein, favors complete excision in all cases in which no contraindications are present; that, following this, multiple ligation, or excision combined with multiple ligation, is advocated; and, in cases in which these measures are contraindicated and the entire saphenous vein is dilated, trial of the high ligation of Remi and Trendelenburg. Also, arguing from the ætiology, pathology, and proneness of the varix to extend, the author advocates early operation. The tendency is too much toward palliation in this disease, especially in its early stages. Under palliative treatment, the disease too often extends until serious complications occur, or operations of magnitude are demanded. By removing the diseased vein when the diseased area is small and localized, the varix may be permanently cured. If more early operations were done, we should see fewer extreme cases in which the whole or a large part of the saphenous vein and its branches are involved.

Two Unusual Cases of Aphasia, with Special Reference to the So-called Naming Centre. By Dr. Græmc M. Hammond.—From a consideration of the two cases presented, the author concludes that the presence of word blindness and word deafness, either alone or in combination, does not always imply that the lesion is to be found in the higher visual or higher auditory centres or in both, but that a lesion in any part of the speech area may so disorder the complex mechanism of the associated speech centres, that any or all forms of sensory aphasia may be induced. This view of the case receives further con-

firmation by the conditions which almost invariably accompany the so-called motor aphasia, agraphia, the impossibility of combining numbers, and the frequently coexisting amnesia.

The naming centre has yet to be found; at present it lies in the dreamland of theory only.

Boston Medical and Surgical Journal, December 27, 1900.

Operative Treatment of Goitre. By Dr. J. Collins Warren.—The operative treatment of tumors of the thyroid gland appears to be indicated in rapidly growing tumors in young persons in whom the medical treatment has been ineffective. The operation consists in the removal, by a U-shaped incision, of a limited portion of the gland, such as an isolated lobe or a more or less independently growing adenomatous mass of solid gland tissue, or in the enucleation of a cyst. All vessels should be tied with scrupulous care, silk being far better for this purpose than any of the forms of animal ligature. The dressing should be so applied and should consist of such materials as will give support without causing pressure. For this purpose the horse-collar dressing may be applied; rigidity being given to the collar by paper or pasteboard.

Many cases yield to medical treatment, and it is estimated by Kocher that ninety per cent. of the patients who come into the hospital at Berne are so improved by medical treatment that operation is not necessary. Since the thyroid treatment of goitre has been employed, the author has had comparatively few cases sent to him for operation, but he has seen quite a number of cases in which the treatment has produced no effect. He is not personally cognizant of a single case in which it has effected a permanent cure.

Statistics of Operative Treatment of Thyroid Tumors. By Dr. Lincoln Davis.—In considering the mortality of the various operative measures, and the causes of death, the author quotes the statistics of Reverdin. In 3,408 operations of which he has details there were 118 deaths. In 1,276 enucleations there were only ten deaths. In 96 of the 118 fatal cases, the causes of death were known. Forty-five were of respiratory origin divided as follows: Pneumonia, bronchopneumonia and bronchitis, 32; asphyxia, 10; fatal lesions of recurrent laryngeal nerves, 3. Twelve cases were due to collapse and shock. There were nineteen of fatal hæmorrhage; none of these followed enucleation. Thirteen deaths were due to sepsis, three deaths to tetanus, one to myxœdema. All operations, in use at the present day, are liable to recurrence since total thyroidectomy is proscribed. About twenty per cent. may be expected to have recurrences. In regard to section of the cervical sympathetic nerves for exophthalmic goitre, the total number of cases treated by this method is fifty, with a cure in eleven; improvement in twenty-nine; no improvement in four; and death in six.

Neoplasms of the Thyroid Gland. By Dr. Charles G. Cumston.—The author has had forty-two cases. With the exception of the malignant cases, the principal symptom complained of by the patients which required relief was dyspnoea, while hoarseness and dysphagia were less frequently prominent; palpitation of the heart was noted frequently. In many of these patients, a careful treatment with iodide compounds had been carried out before the operation, which had only produced a slight improvement in the condition, or none at all. In most cases the sternomastoid muscle was not divided. The author con-

siders the operation of total extirpation as, by far, the better operation in the large majority of cases of goitre. Its great drawback, however, is the possibility of wounding the recurrent nerve. The author considers that the most dangerous place is on the posterior lateral aspect of the trachea, where the recurrent nerve passes before it enters the larynx; and Kocher advises the leaving of a bit of thyroid tissue at this place in order to avoid the nerve at this point.

The Practical Use of Vital Statistics. By Frederick L. Hoffman, Esq.—In an exhaustive paper on this subject, the author well illustrates the value and utility of vital statistics. Unless we have more accurate information and a larger body of collected data as to the diseases of our working people, supported by accurate and extensive statistics as to deaths in different occupations and the ages at which the deaths occurred, the development of industrial medicine will not be possible. What is true of the necessity of such statistics for the purposes of industrial medicine is equally true of all other branches of medical inquiry into the longevity of our people as affected by other determining factors.

Two Cases of Perforating Duodenal Ulcer with Subphrenic Abscess. By Dr. J. C. Pegram.

Medical News, December 29, 1900.

The Nitrite Treatment in Syphilis. By Dr. William Browning.—The method employed by the author aims first to secure the temporary safety of the patient where there is immediate danger, and then more widely as a means to get better results from routine specifics. For this purpose, the hypodermic use is unsuited. Prolonged action without untoward effects is desired, and hence, the more volatile and fleeting preparations, like nitrite of amyle, are of limited value. Administration by the mouth answers best. From one to two grains of the sodium salt are usually sufficient for the earlier doses. In the early stages of progressive dementia and in the glycosuria of old syphilitics, this agent has repeatedly shown its value. In gumma of the brain or cord, nitrites help materially to get the desired rapid action of mercury and the iodides. Specific troubles outside the central nervous system, especially when accompanied by pain, may be thus favorably influenced.

The Failure of the Consensus Judgment with Reference to Tuberculosis. By Dr. Charles Denison.—Just now the prevailing opinion among medical men seems to be in favor of home management and the local hospital treatment of tuberculosis, and every consideration seems to hinge on infection as its cause. This general opinion the author opposes, and devotes an interesting article to demonstrating: (1) That there is a decided advantage in climatic change over the home or the local sanatorium treatment; and (2) that the germ origin of tuberculosis is not the sole cause of the disease, and so is not a sufficient foundation for either its educational or legislative control. He suggests that, as a means for giving incipient consumptives an outdoor life, a movable camp should be formed consisting of from fifty to one hundred invalids. Such a movable camp could be outfitted from one of the cities at the eastern base of the Rocky Mountains in Colorado, and, moving by easy stages, should reach some southern point, such as Tucson, Arizona, by the first of December. After a winter camp of three or four months, a return north could be undertaken by a new route, with the object of disbanding in Denver, or thereabouts, the following October or Novem-

ber. Properly carried out, the results would be better than could be produced by any other system or method of treatment at present known.

The Value of the Schumburg Method of Purification of Water for Military Purposes. By Dr. John H. Huddleston.—The experiments performed have given results quite in accord with those of Schumburg and Pfuhl. The failures have emphasized some of the limitations of the method without discrediting it, and, to one having in mind the typhoid bacillus as the one the destruction of which is particularly desirable, the results are most encouraging. The exact occasions on which this is desirable are numerous. The barracks and camps in infected localities, and vessels taking on water at suspected ports, are notable instances. It is an extremely practicable method. The solution must be kept in sealed vessels, and preferably in vessels that hold just the amount to be used for the special emergency.

A Theory of the Physiology of Spinal Anæsthesia. By Dr. H. H. Stoner.—“Why do the motor neurones escape the paralyzing effect of the solution?” The author believes that it is by no means a fact that these neurones are unaffected by the solution. The cytological structure of their cells certainly undergoes the same morbid change as does that of the sensory neurones, but, owing to the direction of the motor current and the relation of the end plates of the peripheral motor neurones to the muscle fibres, their capacity for transmitting motor stimuli to their destination in the muscle is not seriously handicapped.

As to the manner in which the poison gains access to the cell-bodies; the author's theory is that the axones, occupying the cavity into which the solution is thrown, absorb it and transfer it by way of their vascular supply back to the cell. The neurones most profoundly affected by the solution are those that go to make up the cauda equina. A portion of the nerve here lies exposed, as it were, and floats in the cerebrospinal fluid which is impregnated with the poison.

Philadelphia Medical Journal, December 22, 1900.

The Diagnosis of Calculus Disease of the Kidneys, Ureters, and Bladder by the Röntgen Method. By Dr. Charles Lester Leonard.—The mechanical accuracy of this method is very great. Errors may creep in through faulty technique or lack of skill in reading the negatives. Where, however, the negative secured fulfils the requisite conditions, the experienced eye can detect or exclude all calculi. In some cases it may be as yet impossible to secure negatives with such detail, as in the case of very corpulent or muscular subjects. The majority of failures and errors reported should, however, be attributed to lack of skill or a faulty technique on the part of the operator, and not to any inaccuracy in the method, or to the inability of the Röntgen rays to produce accurate negative or positive diagnosis.

Acute Infantile Endocarditis Following Vaccination; Recovery. By Dr. Warren Coleman.—The diagnosis was based on the following points: (1) the septic arm, which might serve as a focus of systemic infection; (2) the presence of a mitral murmur, the patient's heart being normal a few months previously; (3) the coincident appearance of patches of erythema nodosum on the arms and legs; (4) the septic appearance and septic symptoms—chills and sweating.

The Use and Abuse of Zoological Names by Physicians. By Ch. Wardell Stiles, Ph. D.—It is an incumbent upon physicians to follow zoological customs in deal-

ing with zoological subjects, as it is incumbent upon zoologists to govern themselves by the code of medical ethics in dealing with medical cases.

Primary Carcinoma of the Pancreas, with Reports of Four New Cases. By Dr. Frederick A. Baldwin.—Two of these cases are especially interesting. In them we can trace the development of the carcinoma from those areas of Langerhans, in which the epithelial cells are hypertrophic, through those stages in which the areas of Langerhans are hyperplastic, and others are adenomatous, to those which show cystadenocarcinoma.

Angina Ludovici. By Dr. G. G. Ross.—This disease is an infection of the thick layer of loose connective tissue which fills in the space between the symphysis of the jaw and the muscles of the floor of the mouth. The author presents two cases of this comparatively rare affection. The clinical manifestations and pathological appearances so nearly resemble erysipelas that in an active surgical hospital these cases should be isolated.

A Case of Deciduoma Malignum. By Dr. Joseph McFarland.

Composite Teratoma of the Ovary; Pathologic Report. By Dr. Edgar Allen Jones.—The most interesting feature of this case is the fact that the fetus was so large, and, on casual observation, so well formed, that it could easily be mistaken for an ectopic gestation that had ruptured into the cavity of a preexisting ovarian cystoma.

Dermatomycosis Tonsurans. By Dr. W. B. Reid.—The manner of attack in this case, the tinea unguinum, is considered by all authorities to be the rarest form.

A New Photographometer. By Dr. John Milton Garrett.

December 29, 1900.

Rotary Lateral Curvature and Pott's Disease of the Spine; their Diagnosis and Treatment. By Dr. A. M. Phelps and Dr. D. W. Manton.—Rotary lateral curvature differs from tuberculosis of the spine. It is never produced by inflammation or disease of the spinal column. The authors believe that the aetiology of these curves occurring high in the dorsal or cervical region, is nearly always congenital or rhachitic. A rapidly growing child who sits in a faulty attitude, or stands in such a position as to constantly curve the spine, will often develop rotary lateral curvature. Curves that occur in the lumbar region are usually due to such a cause as this, or to a shortened limb or tilted pelvis. Paralysis of certain muscles may be also a factor, and there have been cases where the intercostal adhesions following the absorption of a pleuritic effusion, have been the cause of great deformity. The deformity in lateral curvature is produced by the absorption of the vertebræ from pressure.

Treatment must be based on rational principles. Lateral curvature should be treated with gymnastics and a support to relieve pressure; and Pott's disease, by fixation to give Nature a chance to repair. A spinal support must be *absolutely unyielding*, or it is entirely useless. When, in Pott's disease, a patient is suspended and a jacket properly adjusted, he is at once relieved from a condition of pain and suffering, and to such an extent that no amount of pressure upon the shoulders produces pain. In rotary lateral curvature of the spine, a plaster corset with lacing is made to fit this suspended and straightened position. For patients who can afford it, the aluminum corset is advised. It is light, durable, thin, comfortable, and can be worn during bathing.

Fracture of the Extremities. A Report of a Second Series of Five Hundred Consecutive Cases. Verified by Radiographs. By Dr. G. G. Ross, and M. I. Wilbert, Ph. G.—This statistical article, though of interest, does not readily admit of summarization. The authors have succeeded in demonstrating the great value of radiography in this connection. In the photographic plate, we have a means of showing all the details of a fracture, and when properly interpreted, we are in a position to say exactly the direction and extent of the lesion, and, in addition to this, we have a complete and correct record of the injury for future reference. By taking two pictures at right angles to each other, it is practically impossible for a fracture, even the slightest *infracture*, to escape us, taking for granted of course that our technique is not at fault. There seems to be little or no difference of opinion as to the scientific value of these rays as an aid to the surgeon; but, until it has been found feasible to properly standardize the making, and consequently the interpretation, of a radiograph, the medical profession should not urge or advise the admission of the x-ray picture as evidence *per se* in a court of law.

Ovarian Cysts in Colored Women, with Notes on the Relative Frequency of Fibromas in both Races. By Dr. Daniel H. Williams.—The author combats the opinion that prevailed until a very recent period, that colored women did not develop cystic tumors of the ovaries, and, in regard to the frequency of fibromas, asserts that, in this respect at least, the colored woman is like her white sister.

On the Use of Formalin in the Dissecting-room. By William Keiller, F. R. C. S. Ed.—The use of formalin has solved, to the author's satisfaction, the problem of keeping the human body for dissection, and, he asserts, that bodies thus prepared keep perfectly on the tables in all weather, at all temperatures, and for indefinite periods, while they are free from odor, and pleasant to handle.

Some Anomalous Cases of Typhoid Fever. By Dr. Augustus A. Eshner.—One of these cases, the author believes to have been typhoid fever without intestinal lesions. No autopsy was made—the diagnosis being based upon the presence of the Gruber-Widal reaction and the total absence of intestinal symptoms.

An Unusual Case of Achylia Gastrica. By Dr. Frank H. Murdock.—In this case the author is assured by chemical investigation that achylia existed for ten months, and morally certain that there was no gastric juice in the patient's stomach for three years; and he believes that its unexpected return was responsible for the sudden attack of nausea and vertigo experienced by the patient. Achylia gastrica is common enough, but it is quite unusual for the gastric secretions to be restored after having been absent for so long a time.

New Slide Lifter and Holder. By Dr. A. H. Stewart.

Amputation of both Feet, the Left Hand and the Right Hand. Saving the Little Finger and Part of the Thumb. By Dr. J. S. Wight.

A Suitable Dress for Defence against Infectious Disease.—When the rank and file of the profession begin to dress properly for attending patients suffering with infectious diseases, they will do so no less for the protection of their business interest than for the sake of personal and public safety. The practice will be certain to receive the stamp of popular approval, and that speedily. The costume proposed by the author consists of a suit of white pajamas, a baker's hat, a pair of tennis shoes, and four rubber bands for the sleeves and trousers.

Journal of the American Medical Association, December 22, 1900.

Treatment of Injuries to the Ureters. By Dr. Byron B. Davis.—When division of the ureters occurs, the following would seem to be the rational mode of choosing the method of repair: (1) when it is possible to perform uretero-ureteral anastomosis, this is the preferable procedure; end-to-end anastomosis being simpler and better; (2) when the distal portion is too short for uretero-ureteral anastomosis, implantation into the bladder should be performed; (3) when there is too much loss of substance to permit uretero-ureteral anastomosis, and the proximal end cannot be brought down to the bladder, even with the assistance of a diverticulum of the bladder, as devised by Van Hook, the least objectionable procedure is probably implantation into the colon.

Epispadic Exstrophy of the Bladder Complete. By Dr. Ap Morgan Vance.—The case presented by the author is an excellent one, and the results of treatment demonstrate the value of autoplasmic work in this connection. In this work, much patience is required both on the part of the patient and on the part of the surgeon, and many difficulties are to be overcome, principal among which are the septic surroundings, the difficulty of drawing away the urine, and the constant lack of rest of the parts due to the tendency to erections. Notwithstanding all the difficulties, the benefits justify one in the efforts at autoplasmic work. Maydl's operation, in the light of future experience, may prove better, but the author believes that, in the hands of the rank and file of surgeons, it is a very grave procedure, to say nothing of the possible future complications that may arise in the way of disease of the kidneys, due to septic invasion from below.

Hæmorrhagic Infection in an Infant Due to the Typhoid Bacillus. By Dr. George Blumer.—It would seem likely that this case was one of congenital typhoid fever in which the bacilli had remained latent in the foetal tissues for a period of four and a half months. The septicæmic character of the disease is characteristic of this class of cases, and the hæmorrhagic tendency is seen at times, both in children and in adults. Among the congenital cases; in P. Ernst's there was a hæmorrhagic eruption during life; and in Janiszewski's case, there were hæmorrhages in the kidneys and in the connective tissue in the neighborhood of the œsophagus. In Dürk's case there were hæmorrhages beneath the capsule of the liver. In discussing the hæmorrhagic form in adults, A. G. Nichols thinks it due to secondary infection with pus cocci. Finally, it is interesting to note that, in this case, the histological appearances almost exactly correspond to those recently described by Mallory, though much slighter in degree than those seen in adults.

Morphological Variation in the Pathogenic Bacteria, with Two Pronounced Examples. By Dr. O. P. Ohlmacher.—A member of the colon-bacillus group, recently obtained from the gall-bladder, bile-ducts, and viscera, in a case of gangrenous cholecystitis and cholangitis, furnishes the more striking of the two examples that the author brings forth for consideration. The polymorphism of this organism, though evident in the pure cultures obtained from the kidney, spleen, and heart's blood, was particularly striking in the original smears and sections from the gall-bladder and bile-ducts, and in the first generation of cultures from these sources. All gradations from minute coccoid or diplococcoid to long, coarse filamentous forms, were observed in the smears and sections from the biliary apparatus. The

coccus, diplococcus, and the short streptococcus-like individuals corresponded precisely to those recently described by Adami, Abbott, and Nicholson, being often so small as to tax the amplification of the one-twelfth inch objective.

Local Use of Guaiacol in the Treatment of Frequent Painful Urination. By Dr. Jesse Hawes.—Guaiacol in a fluid condition should not be permitted to cover the mucous membrane; barely enough to make a surface application is all that is desirable. Thus applied it is an anæsthetic and mild stimulant. It gives rise to much less pain than the usual local applications. No strangury results, as is usually the case when silver nitrate is used. The patient will often retain the urine for hours after the application. Its use is often followed by a lessening of the perineal and suprapubic discomfort after a few hours, and, in the author's experience, a few applications, from five to ten days apart, have been more satisfactory to patient and physician than any remedy previously used. The author states that twenty per cent. of his patients have been cured, while in seventy per cent. marked improvement has followed the use of guaiacol.

Lancet, December 22, 1900.

Pulmonary Tuberculosis in Early Childhood, with Special Reference to its Prevention and to its Diagnosis from other Wasting Diseases. By A. Latham, M. B.—Predisposition—the hereditary and acquired character of the soil—is a most important factor in the ætiology of pulmonary tuberculosis in childhood. Infection takes place either by an infected air supply or by an infected milk supply. The author's observations of the post-mortem lesions in some 3,000 cases, lead him to coincide with the view held by most authorities: *i. e.*, that an infected air supply is much the more common cause, but not the sole one. The bronchial glands may become tuberculous from an infected milk supply; the bacilli pass from the intestinal mucous membrane, by way of the lymphatics, to the bronchial glands. From these glands the process spreads to the lung tissue (1) by direct continuity; (2) by means of the lymphatics but against the supposed lymphatic stream; (3) by ulcerating into a blood-vessel and in this way disseminating the bacilli all over the body; and (4) by ulcerating into a bronchus. The right set of glands is more commonly affected than the left.

The varieties of pulmonary tuberculosis in young children up to the fourth year may be classified as follows: 1. Tuberculosis of the bronchial glands. 2. Miliary tuberculosis of the lungs, dependent upon (a) a rapid primary infection without any discoverable old focus; (b) the rupture of a tuberculous bronchial gland into a blood-vessel with rapid dissemination throughout both lungs, more especially of the lower lobes; and (c) pulmonary infection secondary to other and older lesions, such as tuberculous disease of the testis, bone, etc. 3. Tuberculous bronchopneumonia, dependent upon (a) the tubercle bacilli obtaining a hold upon a simple bronchopneumonia; and (b) direct spreading by the lymphatics of the bronchi. This may go on to confluent bronchopneumonia, cheesy consolidation, or, rarely, to a fibroid condition of the lung. 4. Pulmonary tuberculosis approaching the adult type. Uncomplicated tuberculosis of the bronchial glands gives rise to no distinctive symptoms; there may be signs of a mediastinal tumor, more marked on the right side of the chest. There may be compression of a bronchus, with feeble or absent breathing. There are other pressure-symptoms, varying according to the seat of pressure. Miliary tuberculosis of the lungs seldom occurs in young children except in

cases of general tuberculosis. The general symptoms always precede the localizing ones; often the latter are entirely absent. Progressive wasting with slight fever should always arouse suspicion.

Tuberculous bronchopneumonia may be acute or chronic, but it is rarely arrested, and reaches a fatal termination in from one to six months' time. Its diagnosis is always difficult. A copious crop of downy hair is frequently found on the backs of children who become tuberculous. After the age of six years the type of pulmonary tuberculosis conforms more and more to that seen in adult life. But there is not the same tendency to begin at the apex or to the formation of fibrotic tissue. Extensive excavation is less common, as are hæmoptysis and laryngeal complications.

The prognosis is most grave in miliary tuberculosis of the lungs, due to blood infection; brightest in cases where the tubercle bacilli become engrafted upon a simple bronchopneumonia, following measles or pertussis.

The first step in treatment is to secure against further possibility of infection, either through the air or the food supply. Attention to detail is most important: Fresh air and plenty of sunlight; good, digestible food; precautions against exposure and fatigue. With regard to climate, the chief necessities are an equable temperature and a dry soil. Of drugs, the most beneficial is cod-liver oil, which is really a food; but too much should not be given. Preparations of creosote are often of real benefit. In advanced cases our efforts must be directed towards euthanasia.

On some Disappointments of Surgery. By D'Arcy Power, F. R. C. S.—The author's article concerns itself with the minor unsatisfactory results of operations—the surgical disappointments, which are due to two main causes—either the surgeon promises too much, or his fear of doing harm prevents his doing enough. A frequent disappointment following circumcision is that the cut surface of the prepuce adheres to the glans; this may be avoided by frequent retraction, or by passing the glans through a slit in the gauze dressing. In harelip operations, there is often faulty apposition of the two red edges of the lip; to avoid this, the first suture should be passed at that point. The recurrence of adenoids is a fertile source of disappointment to parents. The operation may be perfectly successful, but the predisposition remains. So that too much should not be promised as a result of removal. The greatest disappointments occur in connection with abdominal operations, especially in those carried out upon the kidney. The formation of a fistula, where it occurs immediately after an operation, can hardly be called a disappointment; but they often occur at a period remote from the operation, when the wound has healed soundly. The trouble is usually with the ligatures used. Disastrous disappointments are often met with in operations for internal strangulation of the bowel, hernia and intussusception. Operations upon the vermiform appendix afford so many surgical disappointments that it is never wise to promise too much beforehand. Mental disturbances often follow operations, and the author cites several instances. Injuries to bones are followed by the most disastrous, as well as the best-known surgical disappointments: Colles's or Pott's fracture, non-union, the formation of a conical stump—in all these, the results may be annoying and disastrous to a surgeon's reputation. Injuries of nerves and dislocations are perennial sources of disappointment.

Observations on Compressed Air Illness. By Dr. F. R. Wainwright.—The author is medical officer to the

Baker Street and Waterloo Railway Tunnel Works, and his observations on the subject of illness induced by exposure to compressed air, are embodied in this article.

An astonishing rise of temperature was noted on "locking-in"; the mercury would rise from 60° F. to 115° F. During "locking-out" he has seen it fall from 90° F. to 45° F. But he does not consider that these changes in temperature play the smallest part in the ætiology of the condition. The pressure in the tunnel varied from twenty-three to thirty-five pounds per square inch, over and above the normal fifteen pounds per square inch of atmospheric pressure. During a period of five months, forty-seven cases of illness due to compressed air, were observed. The pathological effects of compressed air are manifested at two distinct times and are due to entirely different conditions: 1. Those appearing when going into or when actually in the pressure. These are purely mechanical, and consist of pains in the ears, frontal, and maxillary sinuses. The earache is most common, and may be slight or agonizing; rupture of the tympanum may even occur. The injury is never permanent. 2. Those symptoms which are only manifested after leaving the pressure. The most common symptom is pain in the joints, especially the knee- and elbow-joints. These pains usually appear within two hours after leaving the pressure. Epigastric pain and vomiting may also occur. Headache and giddiness are also observed, with visual disturbances. Paralysis occurred in only one case. None of the cases were fatal. The most important points in the diagnosis are the time and manner of the onset. The following theories as to the causation of the disease have been advanced: (1) the exhaustion theory, based on the hypothesis that an increased metabolism follows a stay in compressed air, owing to the greater amount of oxygen present; (2) direct poisoning by carbonic-acid gas; (3) congestion of the brain, spinal cord, and other organs; (4) anæmia of the cord; and (5) supersaturation of the blood with gases, which are later set free on leaving the pressure and enter the surrounding tissues, causing the various symptoms of the disease. The author reviews these various theories, and states his adherence to the last, that of supersaturation of the blood. He believes that it furnishes an adequate explanation of the joint pains, of the paralyses and other manifestations. In the great majority of cases, only one treatment is necessary, and that is recompression, with a subsequent slow decompression, the pressure being reduced not faster than at the rate of one pound every three minutes. For this purpose he uses a medical air lock, the pressure in which can be exactly regulated. In some cases, however, the pains recur, and morphine must be used for their relief.

Interesting Surgical Cases. By Dr. E. P. Thurstan—The author reports the following twenty-four cases

1. Left ovarian cyst; ovariectomy; recovery.
2. Carcinoma of the liver; exploration; death.
3. Extra-uterine foætation; laparotomy; death.
4. Perinephritic abscess abdominal section; unsatisfactory result.
5. Extra-uterine foætation on the left side; laparotomy; recovery.
6. Extra-uterine foætation on the left side; ano-laparotomy death following premature coitus.
7. Hydatids of the brain; trephining; death.
8. Double pyosalpinx; abdominal section; recovery.
9. Tuberculous kidney; removal of left kidney; death.
10. Hydatids of the abdomen; abdominal section; recovery.
11. Uterine fibroids; double oöphorectomy; recovery.
12. Appendicitis; abdominal section; recovery.
13. Strangulation of Meckel's diverticulum; abdominal section; recovery.
14. Ovarian cyst; ovariectomy; death.
15. Stone in the kidney; nephrotomy of the right side; recovery.
16. Hys

tero-epilepsy; double oöphorectomy; recovery with great mental improvement. 17. Large uterine fibroid; double oöphorectomy; recovery. 18. Advanced cancer of the cervix uteri; removal impossible; blood supply tied off; patient still living after twelve months. 19. Cystic ovary; left oöphorectomy; recovery. 20. Internal strangulation in the ileocæcal fossa; laparotomy; recovery. 21. Adhesions subsequent to former ovariectomy; laparotomy and separation of the adhesions; recovery. 22. Traumatic ovaritis on the left side; oöphorectomy; recovery. 23. Hydatid of the liver; abdominal section; recovery. 24. Traumatic varicose aneurysm of the thigh; ligature of the vein and artery; recovery.

British Medical Journal, December 22, 1900.

Syphilitic Diseases of the Tongue. By C. Heath, F. R. C. S.—Primary syphilitic disease of the tongue is a very rare thing. The author has never seen a case. It is not indurated, but there is marked enlargement of the glands beneath the jaw. The commonest secondary syphilitic affections of the tongue are the mucous tubercles and the subsequent fissures. Another frequent symptom is the development of inflammation, superficial in character and followed by shedding of the epithelium. A certain amount of cicatricial tissue results, causing smoothness of the surface of the tongue, recognized as the characteristic "bald patch." Or the inflammation may go on to ulceration, followed in turn by chronic thickening.

The treatment for all of these secondary conditions is the administration of mercury; the iodides are useless. The author uses a mercurial mouth-wash, beginning with a strength of 1 to 2,000 of the bichloride, and gradually increasing it. Mercury must also be given internally; the author prefers inunctions, given at night. Salivation must be carefully avoided; to this end the use of an alum mouth-wash is recommended. There are cases of syphilitic tongue on the borderland between the secondary and tertiary stages, instances of late ulceration. For gumma of the tongue, full doses of potassium iodide are to be given together with a mercurial mouth-wash. Leukoplakia may occur entirely apart from syphilis, the common cause being tobacco. But syphilis aggravates the condition. Local irritation must always be present to produce leukoplakia. A warty condition of the back of the tongue is one of the evidences of syphilis, but it must not be confused with the slight hypertrophy often seen on healthy tongues.

Abstract of a Clinical Lecture on Recurrent Appendicitis. By F. A. Southam, M. B.—This article is based upon a series of fifty cases operated upon by the author. In almost every case the appendix was thickened and occluded at some point in its lumen. On the distal side of the obstruction, the tube was frequently found to be dilated. In fifteen cases suppuration had occurred in the neighborhood of the appendix; in twelve cases a localized abscess was present. In most of the cases where an abscess had formed, the attacks had been frequent. In three instances where the suppuration was diffuse, the attacks had been so numerous that the patients had lost count of them. The formation of pus was usually associated with perforation of the appendix. In one case the abscess presented on the anterior wall of the rectum. Fæcal concretions were found in seven cases, being within the appendix in five instances. In only one instance was a foreign body (a pin) found. Adhesions were present in a majority of the cases. A complication occasionally met with was intestinal obstruction from inclusion of the

bowel in a mass of old adhesions. In forty cases the patients had suffered from three or more attacks; in five cases there had been only one distinct attack. The length of time during which the patients had suffered varied from several months to six years. Of the fifty patients, thirty-five were in men and fifteen in women. More than one half the cases, twenty-nine, were met with in persons between twenty and thirty years old.

Quantitative Colour Tests. By Dr. K. Grossmann.—The author calls attention to the shortcomings of the method of testing the colour sense by means of Holmgren's wools. One very serious objection is the occurrence of a central colour scotoma. Where the light is distinct, the image falls on the scotoma and is not properly recognized. In order to properly test the colour sense, the test object must be (a) variable in colour; (b) variable in size; and (c) variable in intensity. To fulfil these requirements, the author has devised a lantern, revolving in front of which are two metal discs, perforated near their edges with circular apertures filled with glasses of various colours. There is an iris diaphragm by means of which the size of the lighted area may be varied. The intensity of the light is graduated by means of gray glass slips of varying opacity. No questions are asked, the patient simply matching colours. The apparatus admits of the adoption of a standard for the quantitative measurement of colour perception. With the average normal central colour vision (C. V.) reduced to one half for red and green, rejection of the examinee is advisable; reduced to one fourth, it is an absolute necessity.

Remarks on Chronic Enlargement of the Pancreas in Association with or Producing Attacks Simulating Biliary Colic. By G. Barling, M. B.—The object of this communication is to present four cases of enlargement of the pancreas, accidentally found while operating on the gall-bladder or ducts. Two of these cases showed distinct errors in diagnosis, for gall stones were not found, although it was believed that they were responsible for the symptoms. The common features in the cases were enlargement of the head of the pancreas with attacks of colic, and more or less complete blocking of the common bile duct. The pancreatic enlargement was probably inflammatory in nature. Blocking of the common bile duct by inflammatory mischief spreading from the duodenum is a well-recognized cause of jaundice. The four patients are regarded as having suffered from chronic pancreatitis, which in two of them led to an ill-founded diagnosis of gall stones. In the other two, gall stones coexisted, and possibly by inflicting damage on the common duct in their passage, directly induced the pancreatic inflammation.

A Case of Congenital Hypertrophy with Stenosis of the Pylorus. By Dr. H. D. Rolleston and Dr. R. Crofton-Atkins.—The authors report a case of the above-mentioned affection occurring in a full-term male infant, weighing eight pounds and three quarters. The first symptoms—vomiting and convulsions—arose when the child was two weeks old. Temporary relief followed careful dieting, but the vomiting and diarrhoea reappeared a week later, and the child died at the age of seven weeks and five days. Three days before death, dilatation of the stomach was made out, but at no time could any tumor in the region of the pylorus be felt. At the autopsy there was found great hypertrophy, with almost complete occlusion of the lumen of the pylorus.

The authors carefully review the literature on the subject. There are two theories as to its causation: (a)

congenital redundancy of pyloric tissue; and (b) congenital gastric spasm. Obstinate vomiting with constipation may suggest the disease, but a diagnosis cannot be made in the absence of a tumor. The prognosis is extremely grave, but recovery is reported as having taken place in six cases. Rectal feeding may lead to temporary improvement, but in the severe cases nothing short of surgical intervention will be of any avail. In the milder cases, nasal feeding is of value; it obviates the peristalsis induced by deglutition and minimizes the spasmodic stenosis of the hypertrophied pylorus.

Further Observations on Epidemic Arsenical Peripheral Neuritis. By Dr. E. S. Reynolds.—The author's observations are based upon cases seen in the Manchester epidemic of arsenical peripheral neuritis due to contaminated beer. He reports a few symptoms not previously noted. The pigmentation does not occur in fair-complexioned patients, or only to a slight degree. The rash is at first erythematous, especially on the hands, face, neck, and upper part of the chest. It becomes gradually darker, then passes into marked pigmentation, which finally desquamates in small branny scales. Herpes is only moderately common. Neuralgia has been observed in a few cases. Poststernal and epigastric pain has been noted in a few cases, together with breathlessness and weakness on exertion, these symptoms being similar to those seen in beri beri. The interesting question as to how much of the total of its symptoms can be ascribed to arsenic, and how much to alcohol, can hardly be answered at present. The present epidemic can be traced back for over twelve months.

The Strength of the Hypertrophied Bladder. By Dr. D. W. Samways.—When the bladder hypertrophies, its whole wall is strengthened. The interfascicular spaces, by becoming sacculated, are put into what is economically and mechanically the most ideal condition for supporting pressure. When large sacculi develop or spontaneous rupture occurs, the causes are probably additional pathological complications rather than errors in mechanical principles during hypertrophy.

Intraperitoneal Rupture of the Bladder; Operation Four Days after Injury; Recovery. By W. P. Blumer, F. R. C. S.—the author reports the case of a man, aged thirty-five years, who suddenly became giddy on the street and fell, striking his abdomen. All attempts at micturition were fruitless, and four days later he walked two miles to the infirmary. The abdomen was greatly distended, and absolutely dull over both flanks. On passing a soft catheter, 196 ounces of bloody urine were removed. Laparotomy was performed, and a vertical tear on the posterior wall of the bladder was found. The abdominal cavity contained considerable urine. The rent was closed with continuous sutures, the abdomen closed (a drainage tube being left in) and the patient made a gradual recovery. The interesting points are: (1) the length of time between the injury and the operation; (2) the large amount of fluid in the abdomen, causing comparatively little trouble; (3) that four days after the injury the patient walked over two miles; and (4) the absence of symptoms of peritonitis.

Notes on a Case of Profuse Hydroperitonæum Complicating Uterine Fibroids.—The author reports a case of hydroperitonæum in a woman suffering from uterine fibroids, following an accident in which she was knocked down by a cart and severely bruised. The following points are of interest: (1) the ovaries and tubes were healthy; (2) the tumors removed were simple fibromyomata; (3) up to the date of the accident no free fluid had

been discovered in the abdomen; (4) emaciation was first noticed, and free fluid in the abdomen first detected, about six weeks after the accident; (5) so far as could be ascertained, the patient was free from thoracic or abdominal disease; (6) though aspiration was performed five times in six weeks, yet there was no reaccumulation of fluid after the supravaginal hysterectomy, and the patient remains in perfect health.

The hydroperitonæum was directly caused by the injury to the peritonæum covering the fibroids.

Otomycosis in the Tropics. By Dr. H. C. Highet.—Otomycosis is very common in Singapore and Bangkok. All the cases seen were in adult Europeans; children are said to be exempt from the disease. There may be simply blocking of the external auditory meatus, or there may be considerable pain and discharge. Where acute diffuse inflammation supervenes, the pain is intense. The meatus is filled with a soft, wool-like substance, varying in color from pale yellow to pale green, according to the particular type of fungus present. In chronic cases, sodden impacted masses will be found in the meatus. The prognosis is good, as the disease is readily curable. As much of the fungus as possible should be removed with a probe and cotton; the canals should then be syringed with a warm 1 to 5,000 bichloride solution. They are then to be wiped and dried with cotton wool and finally sponged out with a 1 to 1,000 solution of bichloride in absolute alcohol. This causes considerable pain for a moment, but it soon passes off. After the fungus has ceased to grow, a powder of boric acid, bismuth salicylate, and oxide of zinc, should be insufflated.

Some Points in the Treatment of Spinal Abscesses. By A. H. Tubby, F. R. C. S.—1. Do not wait to open a spinal abscess until the skin is reddened and involved. 2. So far as possible open the abscess at certain "seats of election," the places of evacuation to be decided by the direction taken by the abscess and by the surgeon. 3. Whenever evacuation is decided upon, let it be done, so far as possible, away from the groin, and in such a position that more than one opening can be made into the abscess cavity. 4. Carefully cleanse the cavity and rub the interior thoroughly with iodoform or menthol solution. 5. Avoid drains of all kinds. 6. Be careful to carry out perfect aseptic measures from first to last.

A Case of Restoration of the Lower Lip after almost Complete Excision for Epithelioma. By Dr. R. Kennedy.—The author reports a case where restoration of the lower lip was effected by means of Trendelenburg's operation. Sixteen months later, no retraction of the lip from scar formation had taken place, and the patient was able to use the lip perfectly.

Two Cases of Blindness Due to Sphenoidal and Ethmoidal Sinus Disease, both Cases Terminating Fatally Necropsy. By Dr. G. V. Miller.

Complete Prolapse of the Rectum Successfully Treated by Intra-abdominal Fixation. By T. S. Kirk M. B.—The author reports a case of this affection in a male child aged twelve months, where the prolapse of the rectum refused to yield to the ordinary modes of treatment. The abdomen was opened in the left iliac fossa; the iliac fascia was exposed and the bowel was stitched with a fine continuous silk suture to the exposed area. The child made a rapid recovery, and the rectal prolapse has not recurred. The only objection to this apparently ideal operation is the risk of a subsequent ventral hernia; and this can be minimized to a great extent by splitting the muscles and aponeuroses so far as possible and not cutting them.

Presse médicale, December 5, 1900.

Affections of the Vascular Apparatus.—M. Hutinel writes an historical review of the views held on the diseases of the heart and its valves and of the blood-vessels during the present century. (*To be continued.*)

Berliner klinische Wochenschrift, December 3, 1900.

Diabetes Mellitus.—An historical review by Professor von Noorden.

Chronic Diffuse Œdema of the Skin with Involvement of the Larynx.—Dr. W. Lublinski reports such a case in which no nephritis existed, neither was there a myxœdema, nor could the diagnosis of diffuse scleroderma be made as the skin was pale and not bluish-red. The patient improved under treatment by thyreoid extract, but was not completely cured.

Results of Thyreoid Therapy in Sporadic Cretinism.

—Dr. H. Neumann says the most striking result is the diminution of the myxœdematous symptoms, especially in the loss of weight due to the lessening of the amount of unhealthy tissues. The increase in stature was next noted, the growth being mainly osseous, the teeth showing in this development. The cerebral symptoms also improved markedly. The treatment must be begun as soon as possible after the initial period of the disease, in order to gain the best results.

Treatment of Fractures of the Jaw.—Professor Warnekros writes of the prosthetic apparatus to be used in these cases and urges a more general recognition on the part of the profession of the methods now available, especially the guttapercha plate for use within the mouth.

Treatment of Nervous Diseases at Home.—Dr. R. Gnauck speaks of the difficulties and the best methods of overcoming them.

Deutsche Medizinal-Zeitung, December 10, 1900.

Diplococcus Influenza.—Dr. Schtschegolew describes a number of cases which ran the clinical course of influenza and seemed to be contagious, in which he succeeded in isolating a diplococcus that had some biological distinction from the ordinary diplococcus found in pneumonia. The same organism was detected in cases of acute conjunctivitis. One of the patients developed pneumonia and died of it. The author thinks the morphological differences may be attributed to the changes which take place when the diplococcus of Fränkel and Weichselbaum is transplanted to agar.

December 13, 1900.

Light Therapy and Electric Light Baths.—Dr. Max Heim says that the influence of electric light upon the activity of the cells and increased metabolism is absolutely proved. Chlorosis and anæmia, rheumatic affections, gout, obesity, neuralgias, colds, multiple sclerosis, tertiary syphilis, arthritis deformans and neurasthenia have all been favorably influenced, partly through beneficial blood changes and in part by heightened metabolism. Psoriasis and allied skin diseases have likewise benefited under the light treatment. He says the treatment should, however, not be used alone, but in combination with general therapy.

Centralblatt für Chirurgie, December 8, 1900.

Use of the Bur for the Division of Flat Bones.—Dr. Paul Meisel describes in detail his invention of a bur which is of especial use in the division of flat bones, such

as the skull. In the Freiburg clinic it has been used for osteoplastic trephining of the skull with eminent success.

Wiener medizinische Blätter, December 13, 1900.

On Chronic Myocarditis.—Dr. J. Wahringer divides the ætiological factors of chronic myocarditis into two stages, the presclerotic and the cardio-arterial. The latter is characterized by increased blood pressure, peripheral endarteritis and, later, by involvement of the internal organs and the vessels of the heart. (*To be continued.*)

Münchener medicinische Wochenschrift, December 11, 1900.

Traumatic Movable Kidney.—Dr. Erwin Paye has seen cases in which severe massage of the lumbar and abdominal muscles, undertaken for other diseases, has evoked a movable kidney. This may arise further from a severe fall upon the feet or the buttocks, or from constant irritation of the kidney with a tendency to downward displacement while the trunk is immovable, as in horseback riding. It may arise from severe lumbar injury, great compression of the thorax, or severe muscular exertion. There is always probably a disposition for the kidney to be easily moved on a change in the abdominal balance of pressure. (*To be continued.*)

Action of Various Poisons upon Distoma Hepaticum. By Professor von Tappeiner.

Iodine Poisoning from Potassium Iodide.—Dr. O. Muck reports two cases in which an iodine acne, nausea and other symptoms appeared in varying intensity.

Immobile Butyric-acid Bacilli and their Relation to Anthrax Affections. By Dr. A. Schattenfroh and Dr. R. Grassberger.

Small-pox Epidemic of the Summer of 1900.—Dr. Martin Kauffmann reviews the features of the small-pox epidemic in Frankfort last summer. The epidemic lasted three months and not one case developed among the *personnel* of the hospital, all having been vaccinated as soon as the outbreak occurred. There were in all twenty-seven cases. Patients who had been vaccinated under twenty years were all lightly affected; but those whose vaccinations had been undertaken fifty years or more ran severe courses. Between these periods, the cases were moderately severe. Four patients were successfully vaccinated while they were suffering from variola, one of them dying of the disease. Only one patient was received who had been vaccinated under six years before the epidemic.

Case of Lichen Obtusus. By Dr. G. Hügel.

Chloral and Hæmorrhage.—Dr. E. Model says that owing to arterio-sclerotic conditions he took chloral or bromides for some time and invariably suffered from hæmorrhages from the stomach, lungs or nose whenever he made great physical exertion, such as long walks or mountain climbing. Immediately upon stopping the drug, the hæmorrhages ceased. The author says, therefore, that drugs which lower the blood pressure are better not taken when arterio-sclerosis exists.

Vaccinations in Bavaria in 1899. By Dr. L. Stumpf. —A statistical review.

Medicinische Woche, December 10, 1900.

Retrospect of the Artificial Foods.—Dr. Vollmann thinks that, although tropon and plasmon are nutritive to a high degree in cases of malnutrition and convalescence from wasting diseases, they are still too dear to be of universal use. He looks for some combination, possibly

of casein and meat albumin, which, with the same nutritive power, will be within the reach of all.

Riforma medica, November 27, 1900.

Werlhof's Disease: Treatment with Endovenous Injections of Bichloride of Mercury. By Dr. Arnaldo Lu-signoli.—The author reports three cases in which intravenous injections of mercuric bichloride were given in order to introduce into the system an antiseptic that would counteract the infectious agent of the disease, whatever this agent may be, in a manner analogous to that already used in malarial infection with injections of quinine. In addition to the three cases whose histories are given, the author mentions two other instances of Werlhof's disease which yielded to injections of bichloride, and a sixth case in which the patient was moribund when admitted to the hospital and died in a short time in spite of the injections. The author's conclusions are as follows: (1) The hæmorrhagic diseases, scurvy, purpura, peliosis, are due to the presence of a micro-organism whose products circulate in the blood of the patient. (2) These diseases can be distinguished from one another only by their intensity. (3) These diseases can be successfully treated with intravenous injections of bichloride of mercury.

November 28 and 29, 1900.

The Treatment of Purulent Cystitis with Irrigations of Sulphocarbolate of Zinc. By Dr. A. Scarcella, and Dr. E. Sapuppo.—The authors' experience with this mode of treatment enables them to state that irrigations of the bladder with two-per-cent. solutions of sulphocarbolate of zinc constitute a very efficient therapeutic measure in purulent cystitis, because this salt is an energetic antiseptic, and yet is well tolerated by the system. These irrigations were sufficient, without any other treatment, to combat the most obstinate cases of cystitis. The authors give the histories of nine cases and mention twelve other cases of purulent cystitis in which a complete cure was accomplished in a comparatively short time by means of injections of sulphocarbolate of zinc. They used a double-current catheter with continuous flow or an irrigator of Cantani's pattern, and employed a litre or more of the solution at each irrigation. They recommend that the urethra be flushed out with the sulphocarbolate solution before the sterilized catheter is introduced, in order to remove the pus that may have adhered to the urethral wall. On the second or third day, the local symptoms usually disappeared, and the introduction of the catheter was no longer painful. The urine of the patients was examined daily in order to observe the manner in which the inflammatory process receded. At first, the globules of pus disappeared from the urine; then followed the crystals of triple phosphate; the epithelial cells, however, persisted until after the patient had been discharged cured. In some cases the crystals of triple phosphate disappeared before the pus globules.

Gazzetta degli ospedali e delle cliniche, November 18, 1900.

Concerning Intestinal Obstruction Due to the Diverticulum of Meckel. By Dr. R. Caminiti.—Cases of this kind are comparatively rare, and Provera collected only thirty-eight cases of intestinal obstruction due to this cause in which operations were performed. [Bérard and Delore (De l'occlusion intestinale par le diverticule de Meckel, *Revue de chirurgie*, Paris, 1899, Nos. 5 and 6)

state that the diverticulum of Meckel persists in one person out of fifty-five.] The author reports the history of a case of obstruction due to Meckel's diverticulum which he operated on in 1897.

The patient was a man aged thirty-six years who had been suffering from digestive disturbances for a considerable length of time. In May, 1897, he was seized with an abdominal pain after an imprudence in diet. The pain grew steadily worse, and on the second day there was complete absence of defæcation in spite of all possible remedies. Tympanites, borborygmi and increased peristaltic movements were observed, and it was noticed that the pain seemed to radiate from the right iliac fossa through the rest of the abdomen. In this region there was also felt a resistant mass of the size of a foetal head, but without distinct outlines. Vomiting of food began on the fourth day and became speedily fæcal in character. Then operation was decided upon. When the abdomen had been opened, it was found that a band as thick as an ordinary quill extended from a loop of small intestine, beginning at the side farthest away from the mesenteric attachment and extending to the umbilicus. This band was provided with a mesentery near its attachment to the small intestine. The portion of intestines to the right of the band was free, but a loop, shaped like a horseshoe, was found adherent to the abdominal parietes. This loop was from twelve to thirteen centimetres in length, and was adherent for a distance of from five to six centimetres in front and behind by means of old and firm adhesions. Under this loop, which was thus held down by adhesions and by the band above described, a larger loop of small intestine had "insinuated itself" and had become strangulated. The band was cut at the umbilicus and at the intestinal attachment, and as it was found to be a pervious diverticulum, the gap in the intestine was sutured by Lembert sutures. The adhesions were next separated, and the large loop of intestines was freed. It was found to be about forty centimetres in length, congested, and dark red in color. The intestines were replaced and the incision united by three rows of sutures. The patient died on the fourth day after the operation, probably from an intestinal toxæmia. The author cites several similar cases in which death occurred apparently from toxæmia after the operation (Pearce Gould and others in the London Clinical Society, December, 1897). On histologic examination it was found that the band was Meckel's diverticulum and was pervious for about one half its length. Its mucosa contained numerous follicles of Lieberkühn. A statistical review of forty-six cases of this kind is also given. Of these cases, thirty-six proved fatal after operation. Only three occurred in women, and all the rest were in men under fifty-one years of age, except one, who was sixty-two years of age.

Concerning a Case of Quincke's Disease. By Dr. B. Zamboni.—The author reports a case of angeioneurotic œdema, which he observed in his clinic in January, 1897. The patient was a man aged thirty years, who presented the typical symptoms of what Senator called *hydrops articulorum intermittens*, but, in addition, there was œdema of the face, the scrotum, the buttocks, and of the glottis, giving rise to the phenomena of suffocation. The same condition was found in the patient's father and brother.

December 2, 1900.

Skin-grafting with Pieces of Skin Obtained from Hens. By Dr. Emilio Bianchi and Dr. P. L. Fiorani.—The authors report a satisfactory result obtained by skin-grafting with hen's skin according to the method sug-

gested by DeFrancesco. In this case the defect in the skin was very large, and, although a part of the ulcer was covered with skin-grafts from a child, it was impossible to obtain sufficient skin to cover the remainder. A young hen was obtained and a portion of skin was thoroughly cleaned, deprived of feathers, and disinfected. Fourteen strips of epidermis and derma, about one square centimetre each, were removed from the lateral portion of the chest of this hen, and were put in position on the wounded surface so soon as they were cut off, one by one. These strips were disposed in three parallel lines on the defective surface; the lateral lines were one centimetre distant from the respective margins, and the middle line was two centimetres distant from the lateral lines on either side. The wound was dressed with sterilized gauze and with sterile cotton. The surface was washed with sterile water on the seventeenth day, when the grafts were all found adherent and in good condition. On the nineteenth day, the grafts were observed to increase in size, and in a short time the surface was completely covered. The author adds that the new skin does not "show any signs that would excite the fear of a growth of feathers," and presents a smooth, normally colored surface resembling in all respects human skin.

Concerning a very Rare Case of Complete Occlusion of the Œsophagus. By Dr. A. File-Bonazzola.—The patient was three years old, and, when first seen by the author, he had been unable to swallow any food or liquid for ten days previously. He was given a cup of water to drink, and drank it with avidity, but after a few swallows, rejected the water, mixed with mucus. The mother stated that these attacks had been recurring at intervals for two years. During these attacks the child could not swallow any food and retain it for any length of time. On examination it was found that there was a complete stenosis of the Œsophagus, so that the smallest sound could not enter. The child was too exhausted when brought to the hospital to permit of surgical interference, and died during the first night after admission. On autopsy, a scar was found on the posterior portion of the tongue and the Œsophagus was greatly dilated at its upper end. A fibrous ring was found in the Œsophageal wall at the lower pole of the fusiform dilatation, and about five centimetres and one half from the upper end of the gullet. In this ring a mass of bread crumbs was found tightly wedged. On the removal of the crumbs a No. 12 sound passed through the ring. On incising the fibrous ring, the author found an ulcer of the Œsophageal wall about one centimetre in diameter, and round in shape, with hard, prominent margins. It is probable that the whole trouble arose from the swallowing of some caustic substance. In all probability this substance was lye, for such cases are not uncommon in Rome. Œsophagotomy performed in time would have probably saved the child.

A Case of Otitis Media Purulenta with Mastoiditis and Symptoms of Diffuse Meningitis. By Dr. Salvatore Satullo.

Scottish Medical and Surgical Journal, December, 1900.

The Invention and Evolution of the Midwifery Forceps. By Dr. A. R. Simpson.—An inaugural address.

Organotherapeutics, Especially in Relation to Mental Diseases. By Dr. C. C. Easterbrook.—General conclusions. Brown-Séguard's generalization, that "all glands and all tissues have an internal secretion, all injected subcutaneously have a tonic effect," undoubtedly

requires modification. The animal extracts, consisting mainly of simple proteids (albumin and globulin) and albuminoids, merely have a dietetic value; but those which are rich in nucleins and nucleoproteids produce, when given by the stomach and in sufficiently large doses, a temporary stimulation of cell-catabolism with a subsequent anabolic reaction, this being evidenced by the common increase of the water, total solids, urea and phosphoric acid of the urine, by the general tendency to a sub-febrile pyrexia, and, perhaps, most important of all, by the initial loss in weight followed by a gain. These substances may thus be termed "metabolic tonics." Apart from the general tonic effect upon cell metabolism, it is extremely doubtful whether each organ possesses a specific internal secretion. Some organs do, as witness the thyroid and suprarenal glands. Thyroid extract stands far above all the others in the stimulation of catabolism or tissue oxidation, and, when it is administered in large doses, the anabolic reaction never sets in until after the cessation of the use of the drug. Whereas, in the case of all the other "metabolic" extracts, an anabolic rebound generally sets in during the continuance of the administration of the drug.

Four Cases with Affections of Multiple Abdominal Organs. By Dr. R. C. Buist.—The cases here reported were as follows:

1. *Medullary cancer of both ovaries; pelvic cyst.* The operation itself was successful, but the growth soon recurred and death took place in a few weeks.

2. *Left ovarian cyst; right hydrosalpinx; encysted appendix vermiformis.* Operation followed by recovery.

3. *Gall-stones; cystic left ovary; retroflexion of uterus; right femoral hernia.* Operation followed by recovery.

4. *Malignant deciduoma of uterus and right ovary.*

Angina Ludovici; a Favorable Case. By J. T. Fox, M. R. C. S.—The author reports a case of the above-mentioned affection occurring in a boy aged fifteen years, following exposure. Onset sudden. The whole sub-maxillary region seemed involved in a tender, elastic, resistant swelling, almost symmetrical, similar to that of mumps, but the parotids were not affected. On the third day, the floor of the mouth was coated with a thick, white, false membrane. The swelling of the neck localized itself on the left side, and on the seventh day suppuration took place. The pus escaped by an incision on the floor of the mouth near the canine tooth. Examination of the pus showed many micro-organisms, principally staphylococci and streptococci. Convalescence was established in a fortnight.

Difficulties in Labor Due to Shoulders. By Dr. R. G. M'Kerron.—The author reports two cases of difficult labor due solely to the size of the child's shoulders. In one case, the child was still-born: in the other it became necessary to eviscerate the infant. In one case, pregnancy had been unduly prolonged. He reviews shortly the conditions in which the shoulders may be arrested and the various methods of overcoming the difficulty, and closes by agreeing with Hirst, who recommends it as a good rule of practice to allow no woman to exceed the normal duration of pregnancy by more than two weeks.

American Journal of the Medical Sciences, December, 1900.

A Case of Malaria Presenting the Symptoms of Disseminated Sclerosis, with Necropsy. By Dr. William G. Spiller.—The case reported was one with the symptom—complex of disseminated sclerosis—largely unilateral. A

few cases of disseminated sclerosis attributed to malaria are reported, but none with necropsy. This report is of great interest. Unfortunately, a brief quotation or abstract cannot do it justice, and the perusal of the original is commended.

The Cortical Localization of Sight and Hearing. Report of a Case of Blindness (Slight Light-perception Remaining) and Deafness Due to Cerebral Lesions. By Dr. Clarence A. Good.—The author points out the several steps of progress we have already taken in the direction of cortical localization, and the works of Ferrier, Schäfer, Von Monakow, Henschen, and others, are referred to. His own observation follows in minute detail. His general conclusion is that destruction of the cortical visual areas will lead to a degeneration of the cells in the geniculate ganglia, and the corpora quadrigemina, and to a degeneration of the nerve fibres of the optic tracts and nerves. The macula lutea of one eye is in connection with the opposite angular gyrus.

The Leucocyte Count in Serous Pleurisy. By Dr. John Lovett Morse.—Serous pleurisy is only exceptionally accompanied by an increase in the number of white corpuscles, and then only intermittently so. The white count is of value in two ways in the diagnosis of serous pleurisy: If the physical signs are doubtful and there is no leucocytosis, the condition is almost certainly not pneumonia or empyema, but serous pleurisy. If there is a serous pleurisy and a continuous leucocytosis, some complication is present. The white count in serous pleurisy affords no information as to the duration of the process, the amount of the fluid, and its increase or diminution. The number of white cells is not influenced by the presence of blood or microscopical pus in the fluid or by the degree of fever.

The Operative Treatment of Cirrhosis of the Liver. Report of a Successful Case. By Dr. Charles H. Frazier.—Though the operation for the relief of ascites due to cirrhosis of the liver was suggested some years ago, it is only recently that it seems to have attracted the attention it deserves. Suffice it to say that the author's case was typical. As to the operation, it was commenced under local anæsthesia, but after opening the peritoneal cavity, the manipulation elicited so much pain that it was necessary to finish the operation under ether narcosis. The parietal peritonæum of the abdominal wall on either side of the incision was rubbed quite vigorously with a gauze pad, and the very much thickened and contracted omentum was sutured to the parietal peritonæum and to the margins of the wound. The fluid contents of the abdominal cavity were evacuated and the incision closed without drainage. Convalescence was uninterrupted; the patient suffered no ill effects from the operation: the wound healed throughout by first intention. Three months have elapsed since the operation. On the thirteenth day, 328 fluid ounces were withdrawn: on the thirty-sixth day only 96 ounces were withdrawn. There has been no further accumulation of fluid; the patient is no longer bedridden, but goes out daily, and receives no medication other than enough citrate of magnesium to insure a daily evacuation of the bowel. A table of all the previous operations is given.

These cases are so hopeless, the technique so simple, the dangers so trivial and the outlook so promising, that the prospects of this mode of treatment becoming an established one seem bright.

Report of a Case of Extensive Dissecting Aneurysm of the Aorta. By Dr. Herbert Swift Carter.—The special points of interest in the author's case are: (1) The

generally dilated condition of the arteries throughout the body. (2) The presence of an accompanying sacculated aneurysm. (3) The fusiform dilatation of the dissecting aneurysm above the origin of the cœliac axis, partially filled with laminated clot. (4) The dissection taking place anteriorly. (5) The complete transplantation of two branches of the aorta. (6) The original opening of the inferior mesenteric artery shown closed by a fibrous nodule.

On the So-called "Irritable Bladder" in the Female. By Dr. Frederic Bierhoff.—The term "vesical hyperæsthesia," or "irritable bladder," is in almost every case in the female erroneously applied. As a true *neurosis*, vesical hyperæsthesia rarely occurs. Where vesical hyperæsthesia exists, it does so only as a symptom. The diagnosis of the causative factor must rest upon a thorough examination, not only of the bladder, but also of the urethra, genital and pelvic organs as well. The treatment must be directed against the local changes and the causative factors.

Brooklyn Medical Journal, December, 1900.

Artificial Illumination. By Dr. L. A. W. Alleman.—A very interesting and readable article on the various methods of lighting both streets and houses. The author speaks highly of the incandescent gas burner. Of acetylene the author says that it "is a light source with which we are destined to become more familiar should it ever be allowed a fair competition on its merits. It should be one of the least expensive of all light producers. It can be made perfectly safe, despite the outcry against its danger, and is a light of superior quality. It is said to give the nearest approach of any artificial illuminant to true sunlight color values, which would highly recommend it in industrial plants and shops where the colors are important. It is a highly concentrated light, and should, on this account, never be used save with proper diffusion."

Vacuum tube lighting is discussed as "one of the startling promises which Tesla has given to the world," though the author is reserved as regards its becoming a "commercial possibility." The author considers that "the whole problem is one of approximating daylight conditions, and to this end there are two essentials: The concealing of the light source, and the diffusion obtained by making the walls, ceilings and furnishings all act as light distributors." "When a reading or a working light is desired in any part of the room an individual light may be added for this purpose." The author's main thesis is that the lights should be covered by reflectors which protect the eye from the light source and direct the light against the wall and ceiling, to effect which purpose a special shade is described. The following remarks upon a reading light are worthy of reproduction and commendation:

"When a room is sufficiently lighted by the indirect method, reading is possible in all parts of the room, but where this ideal condition is not obtainable the best arrangement for reading is an overhead light, preferably screened by a reflector underneath, and a desk or table light with an opaque shade which will protect the eyes and throw the light down upon the book.

"It is a common error to read by a single light which is thrown upon the book while the room is in nearly total darkness. The brilliancy of the page is supposed to be all that is necessary. A momentary consideration of a well-known fact of retinal physiology will show the reason for the discomfort thus occasioned.

"Retinal sensibility increases rapidly in the dark; on entering a comparatively dark room nothing is seen, but in a moment objects begin to be visible. The sensibility increases most rapidly at the moment of entering the dark room, and proceeds more and more slowly until the limit of sensibility is reached.

"When reading by a single light the room presents practically the dark-room condition; all the retina which does not receive the image of the paper is attuned to darkness. When we look up for a moment, the eye instantly makes the adjustment to the room lighting, and when the brilliant page is again looked at it is almost as dazzling as the sun, the contrast is so striking. No one would think of reading in the direct glare of sunlight. We all appreciate that diffused daylight is far preferable; yet from the frequency with which I find this condition reproduced by a reading light, the fallacy must be widely held, and I would lay especial stress upon this point. An insufficient reading light is less harmful than the extreme contrast of a too bright light in a dark room. If only one light can be had, it is better to use a translucent shade and let the light shine in the eyes; it will do less harm than the green reflector delusion.

"With a proper quantity and location of light for reading, the quality of the light must be determined by individual necessities. In practice, I advise those with sensitive eyes to procure a skeleton shade, and cover it experimentally with a succession of tissue papers in delicate tints, till the one is found which proves most acceptable, which is usually a yellow-green."

Historical and Critical Observations upon the Surgery of the Liver and Biliary Passages. By Dr. George Ryerson Fowler.—An interesting historical article, but unsuited for abstract.

Abscess of the Liver. By Dr. Walter C. Wood.—The avenues of infection are: (1) Traumatism; (2) parasites; (3) direct continuation from adjacent suppurative processes; (4) pyæmia. The portal vein constitutes a septic channel from ulcerations of, and operations on, the rectum; dysenteric ulcers of the colon; appendiceal abscesses; typhoid patches; gastro-intestinal catarrh; septic inflammations of the umbilicus; ulcerations of the stomach and duodenum, etc. The hepatic artery is a channel for septic incursion from distant points, as head injuries, osteomyelitis, gangrene of the lung, purulent bronchitis, septic endocarditis, etc. The inferior vena cava is also a possible channel. Such abscesses are usually multiple, but the tropical single, or so-called "idiopathic" abscess is considered probably pyæmic due to some intestinal lesion, and has been preceded, according to local observers, in from seventy-five to eighty-five per cent. of cases, by dysentery. A parallel is to be found in "facial erysipelas, formerly considered to be idiopathic, but now known to arise from a minute abrasion about the nose or ear." Prompt drainage is the only rational plan of treatment. "Waiting for adhesions to form or for pus to approach the surface of the liver or abdominal wall is more dangerous than early operation. Delay is dangerous in three ways, from septic absorption, from the increase in the extent of liver tissue involved and the number of abscesses, and from rupture." The accepted operation to-day is drainage at one sitting; the best results are reported by those who incise the liver with the cautery. "The usual *abdominal operation* is as follows: A vertical incision four inches in length, commencing at the border of the rib, is made over the most prominent part of the swelling. The peritonæum is incised through

the entire length of the incision. The general cavity is then packed off with gauze. An aspirator is used to locate the abscess and draw off as much of the fluid as possible. The needle must be large, as the pus is usually thick. An incision, one or two inches long, is now made through the liver tissue into the abscess, with the cautery knife, and the cavity sponged out. Its interior is then explored to locate any abscess admitting of drainage through the first one. It is well to curette a chronic abscess, but probably not an acute one. The use of tincture of iodine to swab out the cavity aids the disinfection. The margins of the liver tissue are then united to the skin with half a dozen sutures, using a round needle; a short drainage-tube and moderately firm packing are then inserted."

The Intra-thoracic Operation.—An incision is made parallel to one of the lower ribs adjacent to the abscess. It is wise to excise at least four inches of the rib so as to permit the introduction of the hand. The costal pleura is then opened for the full length. The pleura covering the diaphragm is next incised for two inches and with the diaphragm is stitched to the costal pleura, thus shutting off the pleural cavity. Waring and other authorities advise this precaution. In the only case of this kind that the author has done, he avoided an empyema and obtained a successful result by packing off the pleura as one usually does the abdominal cavity. An aspirator was then inserted into the abscess and the procedure from this point was the same as in the abdominal operation.

Tumors of the Liver. By Dr. Russell S. Fowler.—A useful article of a text-book character.

Letters to the Editor.

CLAY-EATING.

WINSTON, N. C., December 15, 1900.

To the Editor of the *New York Medical Journal*:

SIR: Allow me to ask for information on a subject of which I have seen very little mention in medical literature, viz., clay-eating. This is a practice quite common among adults in certain districts in the South, and not infrequently we are consulted by parents about children who "eat dirt."

Now, is this a habit pure and simple, is it a gratification of a morbid appetite, or is it Nature's demand for some inorganic material not supplied in the individual's dietary? If the latter, what is this material?

Light on the subject of ætiology and treatment is what I would ask of you directly, and of others, through the columns of the *New York Medical Journal*.

THOMAS W. DAVIS, M. D.

**A perverted or depraved appetite is not uncommon among the insane, and is evidenced especially by anæmic or chlorotic girls, women in the early months of pregnancy, and children. According to the *Reference Handbook of the Medical Sciences*, Vol. i, p. 296, under Appetite, the subjects may be divided into those who eat substances unused as food but containing nutritive principles, and those eating objects not assimilable. The first condition is termed malacia; the second, pica. Geophagia, clay-eating, or dirt-eating, is said to be common among certain races of native Africans, and instances occasionally occur among civilized peoples. Geophagy is supposed by some to be possibly hereditary. A neurosis of digestion, bad and insufficient food, chloro-anæmia, in-

flammation of the mesentery and ankylostoma duodenale are also given as causes. The principal therapeutic indication is to seek out and remove the cause. For more detailed information our correspondent is referred to the before-mentioned article.

Book Notices.

Life and Letters of Thomas Henry Huxley. By his Son, LEONARD HUXLEY. In Two Volumes. With Portraits and Illustrations. New York: D. Appleton and Company. [Price, \$5.00.]

HUXLEY was intended for a medical career, and it has been a subject of speculation with many as to the possible influence he might have exerted on medical science had he pursued the study to the end. According to the custom in vogue at the time he began his studies, he was apprenticed to a medical man, a practical preliminary to walking the hospitals and obtaining a medical degree in London. While preparing for the matriculation examination of the University of London, he attended lectures at the Sydenham College, and it was here he won his first prize—the silver medal of the Pharmaceutical Society of Great Britain, awarded in open competition for proficiency in botany. His first scientific paper, published in the *Medical Gazette* in 1845, when he was nineteen years old, announced his first anatomical discovery, that of the existence of a membrane in the root of the human hair, which still bears the name of Huxley's layer. As a student he was successful in all branches of study, winning honors in chemistry, anatomy, and physiology. In 1845 he passed the first M. B. examination at London University and carried off the gold medal for anatomy and physiology.

Huxley, however, cared little for purely medical studies; his great desire was to be a mechanical engineer. The only part of his professional course which really and deeply interested him was physiology, and that because he regarded it as "the mechanical engineering of living machines." Paradoxical as it may seem, his divorce from medicine as the art of healing dates almost from the moment he received his M. B. degree; for soon after graduating, on the recommendation of Sir Joseph Fayrer (the present eminent physician), he applied for and received a commission in the medical service of the navy. After a sojourn of several months at Haslar Hospital, he was appointed assistant surgeon to the *Rattlesnake*, a twenty-eight-gun frigate, which was fitted out for a surveying expedition to New Guinea. His almost complete alienation from purely medical studies after his appointment to the *Rattlesnake* is shown in the fact that the cruise resulted in no contribution to medical science, and we search in vain through the letters for any allusions to his medical work on board ship. Zoology claimed him thereafter, and one of his earliest pieces of research work in biological science was an account of *Physalia*, or the Portuguese man-of-war, as it is called, which was noticed in the *Proceedings of the Linnaean Society*. The cruise of the *Rattlesnake* lasted four years, and, as Professor Virchow has said, made of Huxley a perfect zoologist and a keen-sighted ethnologist:

"How this was possible any one will readily understand who knows from his own experience how great the value of personal observation is for the development of independent and unprejudiced thought. For a young man who, besides collecting a rich treasure of positive

knowledge, has practical dissection and the exercise of a critical judgment, a long sea voyage and a peaceful sojourn among entirely new surroundings afford an invaluable opportunity for original work and deep reflection. Freed from the formalism of the schools, thrown upon the use of his own intellect, compelled to test each single object as regards properties and history, he soon forgets the dogmas of the prevailing system and becomes first a skeptic and then an investigator. This change, which did not fail to affect Huxley, is no unknown occurrence to one who is acquainted with the history, not only of knowledge, but also of scholars."

His work on the *Rattlesnake* received almost immediate recognition. On his return to England, his leadership in science was readily acknowledged, and he was honored in various ways. He was elected a fellow of the Royal Society, being at the time the youngest fellow on record, and membership in learned societies and election to positions of responsibility in scientific bodies, besides appointment to various important government commissions, came in quick succession. The turning point in his career was reached in 1854, when he obtained a permanent lectureship in London. In the same year he was appointed naturalist of the Geological Survey, and closely following this he was offered a lectureship on comparative anatomy at St. Thomas's Hospital, and in September he was asked to lecture for the science and art department at Marlborough House. Up to 1854 Huxley's work had been almost entirely morphological, dealing with the invertebrates. Palæontology and administrative work then began to claim more of his attention, and his essay on Palæontology, published in 1856, was the first of a long series of papers dealing with fossils, the description of which fell to him as naturalist to the Geological Survey.

By his services in expounding the principles of evolution promulgated by Darwin in his *Origin of Species*, he earned for himself the title of the "Great Apostle of Evolution," and his widest renown was probably derived from the matchless skill in controversy which he exhibited in making the discoveries of Darwin clear to the comprehension of the public and giving them the sanction of exact demonstration. Popularly and with many persons of real culture and education, too, Darwin's explanation of the cause of evolution was regarded as a "cupricious and antitheological assertion that men are descended from monkeys." At the Oxford meeting of the British Association in 1860, Huxley made a notable effort to extort a fair hearing for Darwin's ideas. Darwin's theory of evolution was discussed by Bishop Wilberforce in what was considered an unfair and unbecoming way. Bishop Wilberforce attempted to cast ridicule upon both Darwin and Huxley, rallying the latter on his descent from a monkey. "In a light, scoffing tone, florid and fluent," according to an auditor who lately recorded his impressions of the speech in *Macmillan's Magazine*, "he assured us that there was nothing in the idea of evolution; rock-pigeons were what rock-pigeons had always been. Then, turning to his antagonist with a smiling insolence, he begged to know was it through his grandfather or his grandmother that he claimed his descent from a monkey?" This descent to personalities gave Huxley a tactical advantage which he immediately seized upon. Turning to his neighbor, he exclaimed: "The Lord hath delivered him into mine hands." Perhaps the most accurate account of Mr. Huxley's reply (the exact words have been variously reported) is that of Mr. J. R. Green, as follows:

"I asserted—and I repeat—that a man has no reason to be ashamed of having an ape for his grandfather. If there were an ancestor whom I should feel shame in recalling, it would rather be a man—a man of restless and versatile intellect—who, not content with an equivocal success in his own sphere of activity, plunges into scientific questions with which he has no real acquaintance, only to obscure them by a nameless rhetoric, and distract the attention of his hearers from the real point at issue by eloquent digressions and skilled appeals to religious prejudice."

Huxley was a lover of truth and sincerity, and his letters to colleagues in science reveal this salient feature of his mental character. The story of his life is fully narrated in the letters and his conversation, and the biography is thus to a great extent autobiographical. The author lets his father speak for himself, only supplying so much biographical matter as is needed to make a connected narrative and likely to lead to our better understanding of the man.

Almost every subject of human interest claimed the attention of Thomas Henry Huxley; and it would require the most profound expert analysis to give a fitting exposition of his researches into Nature and philosophy. His published works include twelve volumes of collected essays, six text-books still in constant use, and about 150 articles contributed to scientific periodicals, besides many reviews. All who are interested in the history of scientific inquiry in the nineteenth century will be amply repaid by a perusal of these letters and reminiscences compiled by the son of the gifted scientist.

Studies of American Fungi. Mushrooms, Edible, Poisonous, etc. By GEORGE FRANCIS ATKINSON, Professor of Botany in Cornell University and Botanist of the Cornell University Agricultural Experiment Station; Author of *Studies and Illustrations of Mushrooms, Biology of Ferns, Elementary Botany, Lessons in Botany*. With a Chapter on Recipes for Cooking Mushrooms, by Mrs. SARAH TYSON RORER; on the Chemistry and Toxicology of Mushrooms, by J. F. CLARK; and on the Structural Characters of Mushrooms, by H. HASSELBRING. With Two Hundred Photographs by the Author, and Colored Plates by F. R. RATHBUN. Ithica, N. Y.: Andrus and Church, 1900. [Price, \$3.00.]

WHILE the number of people in the United States who are interested in the collection of mushrooms is small as compared with the number of Europeans who have some knowledge of the subject, there has been a remarkable increase of interest in the study of the edible fungi throughout the Eastern United States during the past few years. One of the best indications of the growing interest in mycology is furnished by the appearance of several works on the subject by American authors within a comparatively short space of time, including Gibson's, Taylor's, Peck's, and McIlvaine's, all of which have been published within the past five years. The latest addition to this list is the work of Professor Atkinson, which is devoted especially to the study of the various genera of agarics found in the United States. The most striking feature of the work is the wealth of original illustrations, made in excellent half-tones from photographs, showing numerous typical specimens of each of the varieties described. There are, in all, some 222 figures in the volume, a large majority of which consist of unusually fine photographic plates. There are also some five excellent

colored plates in which the natural colors are reproduced with a very satisfactory degree of accuracy. The descriptions are accurate and are sufficiently broad to embrace the various slight modifications which the type sometimes undergoes, which modifications have been ignored by some popular writers on the subject, to the great confusion of the self-taught student.

As the book is intended for popular purposes, the author has very wisely included a chapter giving recipes for cooking mushrooms, by Mrs. Sarah Tyson Rorer, and also a brief summary of the chemistry and toxicology of mushrooms from the pen of Professor J. F. Clark. This latter chapter will be found of particular interest by physicians who may be called upon to treat suspected cases of mushroom poisoning.

The book will undoubtedly prove of great value to those who are interested in the study of mushrooms from the practical point of view, and to even the trained scientific observer the excellent photographs will be of great interest.

BOOKS, ETC., RECEIVED.

Diseases of the Nervous System. A Text-book for Students and Practitioners of Medicine. By H. Oppenheim, M. D., Professor at the University of Berlin. Authorized Translation by Edward E. Mayer, A. M., M. D., of Pittsburg. First American from the Second Revised and Enlarged German Edition. With Two Hundred and Ninety-three Illustrations. Pp. 5 to 899. Philadelphia and London: J. B. Lippincott Company, 1900.

Medical Electricity. A Practical Handbook for Students and Practitioners. By H. Lewis Jones, M. A., M. D., Medical Officer in Charge of the Electrical Department in St. Bartholomew's Hospital, etc. Third Edition. With Illustrations. Pp. xv-532. London: H. K. Lewis. Philadelphia: P. Blakiston's Son & Company, 1900. [Price, \$3.00.]

The Treatment of Fractures. By W. L. Estes, A. M., M. D., Physician and Surgeon-in-Chief of St. Luke's Hospital, South Bethlehem, Pa. Pp. 216. New York: International Journal of Surgery Company, 1900.

Disinfection and Disinfectants. A Treatise upon the Best-known Disinfectants, their Use in the Destruction of Disease Germs, with Special Instruction for their Application in the Commonly Recognized Infectious and Contagious Diseases. By H. M. Bracken, M. D., Professor of Materia Medica and Therapeutics, University of Minnesota, etc. Pp. 85. Chicago: The Trade Periodical Company, 1900.

A Compend of Diseases of the Skin. By Jay F. Schamberg, A. B., M. D., Professor of Diseases of the Skin, Philadelphia Polyclinic and College for Graduates in Medicine, etc. Second Edition, Revised and Enlarged. With 105 Illustrations. Pp. xv-9 to 291. Philadelphia: P. Blakiston's Son & Company, 1900. [Price, 80 cents.]

Food and the Principles of Dietetics. By Robert Hutchison, M. D. Edin., M. R. C. P., Assistant Physician to the London Hospital, etc. With Plates and Diagrams. Pp. xviii-548. New York: William Wood & Company, 1900.

Proceedings of the Eighth Annual Meeting of the Association of Military Surgeons of the United States, Held in Kansas City, Missouri, September 27, 28, and 29, 1899. Volume VIII.

Abstract of Report on the Origin and Spread of Typhoid Fever in United States Military Camps During the Spanish War of 1898. By Walter Reed, Major and

Surgeon, U. S. Army; Victor C. Vaughan, Major and Division Surgeon, U. S. Volunteers, and Edward O. Shakespeare, Major and Brigade Surgeon, U. S. Volunteers.

Transactions of the Obstetrical Society of London. Volume XLII. Parts I, II, and III.

The Good Nurse. By James H. McBride, M. D., of Los Angeles, California. (Reprinted from the *Chicago Medical Recorder*.)

Some Observations in Dietetics. By Martin H. Thelberg, M. D. (Reprinted from the *Western Medical Review*.)

Röntgen Rays in the Treatment of Skin Diseases and for the Removal of Hair. By William A. Pusey, M. D., of Chicago. (Reprinted from the *Chicago Medical Recorder*.)

Orthopædic Surgery. A Handbook. By Charles Bell Keetley, F. R. C. S., Surgeon to the West London Hospital, etc. Pp. xvii-539. London: Smith, Elder & Company, 1900. [Price, \$5.50.]

Progressive Medicine. A Quarterly Digest of Advances, Discoveries, and Improvements in the Medical and Surgical Sciences. Edited by Hobart Amory Hare, M. D., Professor of Therapeutics and Materia Medica in the Jefferson Medical College of Philadelphia, etc. Assisted by H. R. M. Landis, M. D., Assistant Physician to the Out-patient Medical Department of the Jefferson Medical College Hospital. Volume IV, December, 1900. Pp. vi-18 to 428. Philadelphia and New York: Lea Brothers & Company, 1900.

Thomas Sydenham. By Joseph Frank Payne, M. D. Oxon., Fellow and Harveian Librarian of the Royal College of Physicians, etc. Pp. xvi-1 to 264. New York: Longmans, Green & Company, 1900.

The Medical Examination for Life Insurance and its Associated Clinical Methods, with Chapters on the Insurance of Substandard Lives and Accident Insurance. By Charles Lyman Greene, M. D., Clinical Professor of Medicine and Physical Diagnosis in the University of Minnesota. With Ninety-nine Illustrations. Pp. xiv-9 to 426. Philadelphia: P. Blakiston's Son & Company, 1900. [Price, \$4.00.]

Comparative Physiology of the Brain and Comparative Psychology. By Jaques Loeb, M. D., Professor of Physiology in the University of Chicago. Illustrated. Pp. x-309. New York: G. P. Putnam's Sons, 1900.

A Practical Treatise on Materia Medica and Therapeutics, with Especial Reference to the Clinical Application of Drugs. By John V. Shoemaker, M. D., LL. D., Professor of Materia Medica, Pharmacology, Therapeutics, and Clinical Medicine in the Medico-Chirurgical College of Philadelphia, etc. Fifth Edition, thoroughly Revised. Pp. vii-766. Philadelphia, New York, and Chicago: The F. A. Davis Company, 1900. [Price, \$4.00.]

Sanity of Mind. A Study of its Conditions, and of the Means to its Development and Preservation. By David F. Lincoln, M. D. Pp. vi-177. New York and London: G. P. Putnam's Sons, 1900.

Prehistoric Implements. A Reference Book. A Description of the Ornaments, Utensils, and Implements of Pre-Columbian Man in America. By Warren K. Moorehead. Six Hundred and Twenty-one Figures, showing Three Thousand Specimens. Pp. xv-17 to 431. Cincinnati: The Robert Clarke Company, 1900.

A Manual of Surgical Treatment. By W. Watson Cheyne, M. B., F. R. C. S., F. R. S., Professor of Surgery in King's College, London, etc., and F. F. Burghard,

M. D., and M. S. (Lond.), F. R. C. S., Surgeon to King's College Hospital, etc. In Seven Volumes. Volume V. The Treatment of the Surgical Affections of the Joints (Including Excisions) and the Spine. Pp. xx-370. Philadelphia and New York: Lea Brothers & Company, 1900.

The American Girl of To-day. By George J. Engelmann, M. D., of Boston. (Reprinted from the *Transactions of the American Gynecological Society*.)

Miscellany.

An Analysis of the Symptoms Observed in Cases of Tuberculous Meningitis at the Babies' Hospital.—At a meeting of the New York Neurological Society, held on December 4th, Dr. C. A. Herter read a paper with this title. There had been twenty-four cases of tuberculous meningitis, and in fifteen of them there had been autopsies. In these fifteen cases, six patients were of the age of eight months; seven were a year old or under. In the nine cases without autopsy, six patients were five months old. These figures showed that tuberculous meningitis was not so rare in the first year of life as had been supposed by some writers. Nineteen of the cases had run their course in less than a month. The fontanelle had been decidedly distended in seven of the twenty-four cases, and in three there had been a marked excess of fluid found at the autopsy. In one case the fontanelle had been depressed—the child had been sick for four or five months. In six cases there had been a delay in the closure of the fontanelle. Vomiting had been noted in nineteen of the twenty-four cases, and had been the first symptom in fourteen. In five of the cases where there had been vomiting, the autopsy showed nothing different from the findings in cases that had presented no vomiting. In eleven cases there had been marked constipation. In cases coming to autopsy there had also been tuberculous lesions in the intestine. In several of the cases there were tuberculous ulcers of the colon, and yet constipation instead of diarrhœa had been present. The pupils were unequal in twelve of the twenty-four cases and dilated in the others. The pupils were contracted in only two cases. Nystagmus was observed in four cases, and strabismus in ten cases. In the cases showing strabismus there were marked lesions at the base and in the interpeduncular space. There were general convulsions in fifty per cent. There was no case which did not present either rigidity or convulsions. In cases without meningitis, but with tubercles in the brain, convulsions were not so common. Paralysis was noted in ten of the twenty-four cases, and was monoplegic in a number. The variability of these palsies was a rather notable feature. In the cases without meningitis, but with tubercles in the brain, no paralyses were noted. The *tache cérébrale* was noted in seven cases and flushing of the face in ten. All the cases of tuberculous meningitis with autopsy had presented stupor, or coma, or more or less irregularity of respiration, while these had not been observed in any of the cases with tubercles, but without meningitis. Hyperæsthesia had been noted in only one case, and in only one had there been a well-developed cephalic cry. Retraction of the abdomen had been noted to a greater or less degree in fifteen of the cases of tuberculous meningitis, but not at all in the other cases. The fever had not been high in the uncomplicated cases, and the pulse had shown nothing distinctive. In the cases without meningitis

marked opisthotonos and convulsions had been the rule, and early vomiting had been much less frequent than where meningitis was present. Only two or three of the cases had presented solitary tubercles. In all the autopsy cases the cerebral tuberculosis had been clearly secondary. The intestine was the seat of tuberculous lesions in eleven of the thirteen cases in which the intestine was examined. The knee-jerk was increased in a large proportion of cases, and absent in only two. An interesting feature was that at times the knee-jerk would be alternately exaggerated and absent.

The Indian and Colonial Addendum to the New British Pharmacopœia.—According to the *Lancet* for December 15th, the following is the list of substances and preparations contained in the *Addendum*:

Acaciæ cortex	Kaladanæ resina
Acalypha	Kavæ rhizoma
Acetum mylabridis	Kino eucalypti
Acetum urginæ	Liquor andrographidis concentra-
Adhatoda	tratus
Agropyrum	Liquor aristolochiæ concentra-
Alstonia	tus
Andrographis	Liquor berberidis concentratus
Aristolochia	Liquor coccini concentratus
Arnica flores	Liquor epispasticus mylabridis
Aurantii cortex indicus	Liquor tinosporæ concentratus
Azadirachta indica	Liquor toddaliæ concentratus
Belæ fructus	Mucilago gummi indicî
Berberis	Mylabris
Betel	Myrobalanum
Buteæ gummi	Oleum ajowan
Buteæ semina	Oleum arachis
Calotropis	Oleum gaultheriæ
Cambogia indica	Oleum graminis citrati
Catechu nigrum	Oleum gynocardiæ
Cissampelos	Oleum sesami
Coccinium	Oliveri cortex
Cucurbitæ semina præparata	Oxymel urginæ
Daturæ folia	Picrorrhiza
Daturæ semina	Pilula ipecacuanhæ cum urginæ
Decoctum acaciæ corticis	Pilula urginæ composita
Decoctum agropyri	Podophylli indicî resina
Decoctum cissampeli	Podophylli indicî rhizoma
Decoctum gossypii radicis cor-	Pulvis buteæ seminum
ticis	Pulvis kaladanæ compositus
Decoctum hygrophilæ	Sappan
Decoctum isphagulæ	Succus acalyphæ
Decoctum sappan	Succus adhatodæ
Embelia	Syrupus urginæ
Emplastrum calefaciens myla-	Tinctura adhatodæ
bridis	Tinctura alstoniæ
Emplastrum mylabridis	Tinctura andrographidis
Extractum acalyphæ liquidum	Tinctura aristolochiæ
Extractum adhatodæ liquidum	Tinctura arnicae florum
Extractum agropyri liquidum	Tinctura azadirachtæ indicæ
Extractum belæ liquidum	Tinctura berberidis
Extractum cissampeli liquidum	Tinctura calotropis
Extractum glycyrrhizæ spiri-	Tinctura coccini
tuosum	Tinctura daturæ seminum
Extractum gossypii radicis cor-	Tinctura jalapæ composita
ticis liquidum	Tinctura kaladanæ
Extractum grindeliæ liquidum	Tinctura oliveri corticis
Extractum kavæ liquidum	Tinctura picrorrhizæ
Extractum picrorrhizæ liqui-	Tinctura podophylli indicî
dum	Tinctura tinosporæ
Extractum viburni prunifolii	Tinctura urginæ
liquidum	Tinctura valerianæ indicæ am-
Gossypii radicis cortex	moniata
Grindelia	Tinospora
Gummi indicum	Toddalia
Hirudo australis	Turpethum
Hygrophila	Tylophoræ folia
Infusum alstoniæ	Unguentum gynocardiæ
Infusum andrographidis	Unguentum mylabridis
Infusum azadirachtæ indicæ	Unguentum myrobalani
Infusum coccini	Unguentum myrobalani cum
Infusum tinosporæ	opio
Infusum toddaliæ	Urginæ
Ispagulæ	Valerianæ indicæ rhizoma
Kaladana	Viburnum.

The Rule of the Road.—The following editorial remarks from the *Lancet* for December 1st will apply with equally trenchant force to other cities besides London and other countries besides England:

"Weak, nervous, and elderly people are often made

very uncomfortable by the overcrowding of the London pavements in the more frequented parts, while busy men are driven to despair by the obstacles to direct walking. Of late the inconvenience experienced has been increased by the fact that the people of London are, on the whole, less orderly and well-mannered than those of a previous generation. The deterioration of public manners of the men, and especially of the boys, in the street is a subject of constant remark among those whose memory carries them back only ten or fifteen years. Formerly the observant Londoner on visiting a country town was often struck by the fact that in the provinces the people, as a rule, walked about without any regard to rule, and he noticed that, although the pavements or 'sidewalks,' to use a convenient Americanism, were less crowded there was much more trouble in avoiding collisions with foot passengers than was the case at that time in any part of London. We regret to say that London is now as bad as, or worse than, any country town. The unwritten rule of the pavement—that a pedestrian should walk on the right side—is a most valuable one, and has not only convenience, but some prestige of antiquity, to support it. It does not, however, date back beyond the last century, and it is not, so far as we know, possible to determine the origin of the rule. It probably came slowly into general use in London. Dr. Johnson, while at breakfast in the Highlands one morning, told Boswell that when his mother lived in London there were two sets of people, 'those who gave the wall and those who took it,' and that when he returned from London to Lichfield his mother had asked him to which set he belonged. 'Now it is fixed that every man keeps to the right,' said Dr. Johnson, 'or if one is taking the wall another yields it and it is never a dispute.' This, according to Dr. Johnson, was the state of things in 1772. All well-behaved and peaceable people took the right side, but the rule was not absolutely established at that date, for some few people still 'took the wall.' Why it was a sign of pride and of a quarrelsome disposition to 'take the wall' when to 'go to the wall' was synonymous with misfortune is a question for philologists; we are concerned only to insist that in the present crowded state of the streets of London order and method should be duly observed by pedestrians."

We would suggest, among other New Year's resolutions, one to "keep to the right" in walking along our crowded thoroughfares.

The Effect of City Life upon the Eyesight.—The *Lancet* for November 17th, commenting on the Boer eyesight, says:

"There will be nothing strange or new to ophthalmologists in General Sir Redvers Buller's remarks regarding the eyesight of the Boers. He says:

"Many of our men are city born, and England is not a very large country. We went out to a region where the principal number of our enemies were born in a very open country, a very large country, and it is not untrue to say that practically the vision, the ordinary sight, of our enemy was two miles at least further than the average sight of the English who were fighting against them. That is a matter of actual fact. An ordinary Dutchman or African can see a man coming toward him two miles before the man approaching can detect him."

"If we recollect aright," continues the *Lancet*, "Lord Wolseley has also stated that when he was in South Africa he was impressed with the same fact, and we have heard it remarked that the Boers are not so much better shots as better judges of distance than our own soldiers."

It is well known, and it can be easily accounted for, that savage or less civilized races living in the open air do not suffer from the imperfect vision resulting from defective accommodation of the eye which often obtains among more highly civilized and educated races whose vision has been accustomed and adapted to more and more limited ranges."

The Proposed Change in the Government of Bellevue Hospital.—The following statement regarding the proposed change in the method of managing Bellevue Hospital, which we print by request, is not a complete "brief" of the case, but represents the point of view taken by physicians who have been for many years connected with this hospital:

"The objects which we desire to obtain by a transfer of Bellevue to the care of a governing board are in general these:

"1. The removal of this institution (which is by far the most important one of its kind in the city) from political control.

"2. The establishment of a stable and permanent method of management, by which its interests can be looked after in connection with more carefully studied and systematic policy.

"First. As regards the desirability of the first point, it does not seem that much argument is needed. It happens sometimes that that hospital falls under the control, as it is at present, of an efficient and intelligent commissioner; but there is no assurance that such wise control will be continued for more than one term of office; and, even if any equally efficient man succeeds him, he must again learn the duties of the place, and his interests and activities may develop another kind of policy. Besides, it seems impossible, however efficient the commissioner, that under our political system he can do all that is necessary to secure a well-disciplined and thoroughly organized service. An inspection of the hospital and a comparison of it with other hospitals managed by responsible boards of governors, not subject to outside influences, will show how wide the differences are between the two methods.

"It may be claimed that the plan proposed will not have the effect desired. To this it can only be said that it has been most carefully studied out with the help of the best advice and largest experience obtainable, and it is confidently believed that it will be effective and practicable.

"Second. As to the question of the advisability of having a permanent board of managing officers, it seems also that no argument is needed to maintain the general proposition. It is in this way that all large non-municipal hospitals are managed throughout this country and in England, and they are usually managed well. On the other hand, the city hospitals of our large cities have the same defects, due to politics and changing policies. That the board hospitals are well run, and the city hospitals badly run, is a perfectly well established fact for America. Furthermore, in Boston and Cincinnati, where the method we propose has been tried for many years, it has worked successfully, so that this is not a purely experimental scheme.

"The history of the growth of Bellevue is the damning evidence of the evils of the present policy of its government. Successive administrations have added, changed, rebuilt, and patched up Bellevue until it is now a congeries of buildings, badly and often extravagantly built, unsuitable for effective work, unharmonious and re-

pulsive architecturally. It might be a wise and economical policy to tear everything down and start afresh on a carefully drawn plan. The buildings consist now of

- "1. The Original Hospital.
- "2. Sturgis Pavilion.
- "3. Marquand Pavilion.
- "4. Alcohol Cells.
- "5. Insane Pavilion.
- "6. Emergency Hospital.
- "7. Tuberculosis Hospital.
- "8. Infectious Diseases Pavilion.
- "9. Morgue Building.
- "10. Special Gynæcological Ward.
- "11. Special Gynæcological Cottage.
- "12. Erysipelas Pavilion.
- "13. Drug House.
- "14. Protestant Chapel.
- "15. Catholic Chapel.
- "16. Boiler Building.
- "17. Dispensary Building.
- "18. Porter's Lodge.

"There are, thus, seventeen different buildings, put up at different periods during the last twenty years and arranged without any consistent purpose or in accordance with any wise foresight. Each administration has apparently aimed to do something to distinguish its policy.

"Objections of various kinds can and have been made: 1. That a non-political board cannot be obtained. 2. That the institution can be better run under one head. 3. That it will split up the work of municipal charity and that friction will occur between the board hospital and the other hospitals under the care of the commissioner.

"These objections are matters of opinion and cannot be argued to advantage here. The question must be decided by the judgment of the commission, enlightened by the experience of the present method and of that of other methods. This at least can be said: That, if the great central hospital like Bellevue is organized and run upon the highest possible scale of efficiency, it will surely have a good effect upon the rest of the city hospitals, just as the streets of Brooklyn grew better after New York's were improved."

Discovery of a Statue of Æsculapius in the Roman Forum.—The Roman correspondent of the *Lancet* for December 15th states that among the recent interesting finds in the Roman Forum is a statue of Æsculapius. It was lying face downward under the central niche of the large arched space surrounding the Well of Juturna, which has lately been excavated under the direction of Professor Boni. The head of the figure and the middle of the right arm are wanting, but the other parts are well preserved. It represents the god with a *volumen* (or roll of paper or parchment on a stick) in the left hand, leaning on his staff, round which is coiled the serpent, the symbol of prudence and renovation. Close to the staff is a child, supposed to be Camillus or Telesphorus, the genius of recovery, in the act of bringing the offering of a cock in his left hand and holding in his right hand a small knife with a pointed blade. The well enjoyed a reputation for the salubrity of its water, and this fact explains, no doubt, the presence in its precincts of the statue of the god of medicine, under whose special protection such wells were placed. The worship of Æsculapius is said to have been introduced into Rome from Epidaurus about 293 B. C., but this statue, which is of indifferent workmanship, belongs to a much later period, probably the first or second century of the Christian Era.

Original Communications.

PREVENTION AND MANAGEMENT OF INFECTION OF THE BREAST DURING LACTATION.*

By C. S. BACON, M. D.,

CHICAGO,

PROFESSOR OF OBSTETRICS, CHICAGO POLICLINIC, ETC.

IT is almost unnecessary to refer to the importance of this subject. The facts that the majority of nursing women have wounds of the nipple of greater or less extent, that these wounds result in much suffering, that they frequently become infected, that the infection often extends to the breast and causes abscesses, and, not infrequently, long-continued suppuration, show that the management of the breast is one of the most important obstetrical questions. Moreover, the fact that the disturbance of the breast is the cause of much sickness and mortality among infants, makes this an important subject of pædiatrics.

At the beginning, I wish to call your attention to the distinction between infection of the breast and simple hyperæmia or congestion of the breast. This distinction is necessary, for it is important that the difference between the two conditions should be kept in mind. The establishment of the milk secretion is always attended with more or less painful congestion of the breast, and, later, the breasts are liable to become painfully distended whenever the interval between nursings is unusually prolonged. Infection of the breast, on the other hand, is generally attended with fever, and while it is often confounded with simple congestion, it is entirely a distinct process.

Formerly we heard much of the so-called "milk fever" that comes on during the first week of child-bed, about the time of the swelling of the breasts, and was attributed to the establishment of the milk secretion. It is now well proved that this fever is due to genital wound infection. While the secretion of milk, like the secretion of other glands, is attended with a very slight local rise in temperature, this increase in heat amounts only to a few hundredths of a degree, can be measured only by a delicate thermometer, and cannot properly be called fever. Hence the term "milk fever" should entirely be abandoned. If there is no infection, there is no fever. We have, therefore, to consider only the nature, cause, and the diagnosis of infection of the breast, as a basis for the study of its prophylaxis and treatment.

It has been found that the *Staphylococcus pyogenes aureus*, the *Staphylococcus pyogenes albus*, and in some cases the *Streptococcus pyogenes*, are the infecting germs. It is well known that the staphylococci always, and the streptococci frequently, are found on the skin and in the ducts of the cutaneous glands. They are found, not only around the nipple, but also in the milk channels, and in the milk drawn from sterilized nipples. While it is doubt-

ful if the *Streptococcus albus* found in the milk is the cause of infection, even if there is an abrasion of the lining membrane of the milk ducts, there can be no doubt that the bacteria found in great numbers on uncleaned nipples are a source of danger. Various sources of contamination are the clothing, the fingers of the mother and nurse, and the face and hands of the child. The mother's nightgown, the child's dress and bib, often soiled with overflow milk, are frequently contaminating agents. The fingers of the mother or nurse, perhaps soiled by coming in contact with lochial or fæcal discharges, when used to draw out the nipple, or cause its erection for a better application of the child, are a common source of infection. Perhaps one of the most dangerous infecting agents is the head or hand of the child. For several years I have noticed that severe infection generally occurs in patients whose babies have boils or pustules on the body, or sore eyes. The pustules open spontaneously, and the pus, smeared over the face of the baby, is rubbed into the nipple when the child is put to breast.

There is some dispute between those who hold that germs enter the breast only through the nipple by way of the lymphatics and those who believe that the milk passages are also routes for infection. The general presence of an abrasion in the epithelial layer of the nipple in cases of infection, and the direct route from the erosion to the depth of the breast furnished by the lymphatic channels, which are favorable routes of most pathogenic bacteria, favor the now generally accepted conclusion that the latter is the route of breast infection.

The diagnosis between infection of the breast and simple congestion, on one hand, and genital wound infection on the other hand, is very important. Simple congestion of the breast is generally important, as a disturbing factor, only during the first days of lactation. While it is often attended with the tenderness which is characteristic of an infection, other symptoms, namely, chills, fever, etc., are absent. As soon as these symptoms develop, all doubt concerning the diagnosis between congestion and infection of the breast must cease.

The diagnosis between genital wound infection and breast infection must be made by a study of the predominant local symptoms. The greatest difficulty is experienced when symptoms of infection coincide with pelvic tenderness, distention of the breast, and soreness of the nipples. In such a case the determination may require some delay.

An important point in diagnosis is the determination of the question whether the infectious process has resulted in the formation of an abscess or not. The centre of the infection and abscess formation is often quite deep, and the determination of fluctuation is difficult. The use of diagnostic aspiration with the large hypodermic needle is in such cases the proper procedure. If fever or local pains continue for more than two or three days in spite of proper treatment, the diagnostic puncture should be made.

*Paper prepared for the meeting of the Mississippi Valley Medical Association, at Asheville, N. C., October 9-11, 1900.

Coming now to the subject of the paper, the prevention and treatment of breast infection, we first have to ask, What, if anything, can be done to prevent infection before lactation begins? The laity, as well as the profession, quite universally believe in various local applications, sometimes astringents and sometimes ointments to the nipple. To develop a retracted nipple, some kind of a suction apparatus is frequently used. The latter I believe to be of very doubtful value, and not to be commended. Fatty substances on the nipple serve as bacteria catchers and so are of questionable propriety. The tanning of the skin of the nipple by astringents will not last long after nursing begins. I believe all that need be done is to give attention to cleanliness during pregnancy, and especially careful washing of the nipple with soap and water. In this way the skin of the nipple is made healthy and resistant, and there will be no accumulation of bacteria when the child is first put to breast.

In this connection it is important to remember that a person in good health resists infection better than one with poor digestion, poor circulation, and poor excretion. Every one has observed how differently infection develops in different patients, and we may conclude that these differences are due to variations in the resisting powers of the patients. If two women have similar wounds, contaminated with bacteria from the same source, one will become infected, and the other remain unharmed, because the tissues of one immediately resist the invasion of the germs, and the tissues of the other do not. It is also a common clinical observation that in one patient an infection may begin in the breast, and in a few hours may disappear completely, while in another patient an infection of the same kind may persist, apparently disappear for a few days, reappear, and eventually terminate in an abscess. Such differences in the progress of breast infections, like similar differences in infection of other parts of the body, must be explained by differences in the resistance of different individuals.

It therefore follows that all measures tending to the improvement of the general health, both before and after confinement, are most important in the prevention of breast, as well as all other, infections.

In child-bed or after nursing begins the two principles of prophylaxis are to avoid contamination with bacteria, and to avoid or heal as quickly as possible the nipple wounds. To meet the first indication, it is necessary to remember the most important sources of infection. The common practice of nurses and patients of taking hold of the nipple with the fingers to draw it out for the child to grasp, is quite unnecessary and should be forbidden. When the nipple is not erected spontaneously, a little pressure on the breast outside of the areola is generally sufficient. If it should seem necessary to take hold of a retracted or flat nipple, the finger should be protected by sterilized gauze.

The danger from the child is from pus escaping from boils, pustules, or sore eyes. The pustular eruption on the

neck and face of the child resulting from the easy inoculation of its tender skin with pus germs, is a source of great danger; for the unobserved rupture of a single pustule, and the scattering of its bacteria, is the most common source of infection of the nipple. The management consists in the careful opening of each pustule when it is ripe, the surrounding skin having been thoroughly washed with alcohol, and the evacuation of the matter, leaving the open pustule for some time covered with cotton saturated in alcohol. If the open pustule is on the face, it may be closed with a small drop of collodium. When the face has been contaminated with matter from sore eyes it should be carefully washed before nursing. If one is uncertain how well the washing is done, it is safer to use a nipple shield until the danger is past.

Suppuration in the glands of Montgomery, while not very common, is, while it exists, an important source of danger. Some mechanical injury produced by the nursing child, or by a badly fitting nipple shield, may set up an infectious process. The proximity of the nipple makes such a suppurating gland dangerous. It should be opened like the pustule on a child, and should then be sealed with collodium during nursing.

The general precautions consist in washing the nipples with clean water before nursing, and washing them after nursing with 75 per cent. alcohol, to protect the nipple abrasions from accidental infections from the mouth or skin of the child, and in covering the nipple always with sterilized gauze laid over the breast or attached to the shirt, to prevent contamination with soiled garments or bedclothes. As a disinfectant, alcohol is chosen because it is harmless to the child, and at the same time fairly efficient. Other disinfectants, like carbolic acid or sublimate, cannot be used on account of the danger of poisoning the child. The popular boric acid is of very little disinfectant value, and is practically worth no more than water.

The liability of the nipple to abrasions and wounds depends considerably upon its shape, size, and formation. The most serious wounds, like the deep transverse and perpendicular fissures, are due to malformation of the nipple.

When a nipple is small and not easily grasped, or when, because of the small size of the openings of the ducts, the milk flows slowly, the child must pull very hard on the nipple, and the chances for the production of abrasions are increased.

The length of time that the child is at breast is also important. If the child is nursed for half an hour, or one hour, or lies at the breast practically all night long, the nipple is, of course, macerated, and wounds are easily made and infected.

For the prevention of wounds of the nipple, as well as for their cure, the nipple shield is of very great importance. Properly made and used, it not only saves the mother from much suffering, but also protects her from the dangers of infection. Many of the shields on

the market are improperly made. Frequently they are too short, and the nipple cavity ends in a small opening, into which the nipple is drawn and pinched. Frequently the shields are too small and the nipple is painfully constricted at the base. The flange is often too narrow and improperly formed. The rubber shield does not afford sufficient protection. The flange should be smooth, flat, and nearly at right angles to the bowl, and large enough to cover the areola. The bowl or nipple cavity should be so large that the nipple is not constricted, cylindrical in shape, and deep enough so that the nipple is not pulled too firmly against the end. It may open into a small bulb which serves as a milk reservoir. Such a shield may be used temporarily or intermittently as the case may require, during the first four weeks of lactation. Attention should be given to its care, that it may not become a source of danger. The nipple should be removed and thoroughly washed after each nursing. After washing its outside, it should be turned wrong side out, and the inside thoroughly washed. Then it should be dried with clean gauze and placed, together with the shield, which has also been thoroughly washed with running water or boiled, in a piece of clean gauze. The common practice of putting the shield unwashed into a cup of boric-acid solution and letting it stand for hours is an abomination that should not be tolerated.

When nipple wounds become infected, but before there are any symptoms of general infection or involvement of the deeper breast, the local wounds may be treated like similar wounds in other parts of the body. The application of cotton saturated with alcohol is generally efficient. Nursing through a shield may be allowed.

The appearance of the symptoms of chills and fever generally indicates a deep infection of the breast. When this appears, nursing from the affected breast should be entirely stopped, and the breast should be supported and put at rest by a proper bandage. Treated in this way, from eighty to ninety per cent. of all breast infections will terminate without abscesses. The nipples will heal, and the infective process will be localized and controlled by Nature's inflammatory reaction. Should an abscess form under this plan of treatment, which will happen very rarely, it will be small and confined to one lobe, or part of a lobe.

For supporting the breast and putting it at rest, the simplest form of bandage will often suffice. This is a plain piece of muslin six or seven inches wide, encircling the chest. Its mode of application is very simple, but important. The nurse should distinctly understand that the breast is to be raised and supported, not compressed; with the patient lying on her back, the bandage under her, the nurse takes hold of one end of the bandage with one hand, and of the corresponding breast with the other, and draws the breast up to the middle of the chest, holding it there with the bandage; the patient is then directed to hold the breast in this position with the hand of the same side, the fingers being extended. Then the other breast is raised

and held in the same way, after which the bandage is fastened by several safety pins, the lower border being drawn more tightly than the upper. If the bandage tends to slip down because the patient moves around more or less, strips of bandage over the shoulders may be used to hold it in place.

The double Y bandage holds the breast better than the circular bandage just described. It is made of strong cotton cloth, and consists of a back piece four or five inches wide, and fourteen to twenty inches long. To each end of it are strongly sewed two diverging strips, each from four to five inches wide, and about thirteen inches long. The lower limbs of the Y's which go under the breast are fastened together in front with safety pins, then the upper limbs in the same manner. The upper and lower limbs of the Y's in front may be fastened together with safety pins, to support better the inside of the breasts. With this bandage the nipple of the sound side may be left free, so that the nursing of the child will not necessitate the unfastening of the bandage. If the circular bandage is used, it must be unfastened every time the child is nursed from the healthy side, or an opening must be made over the nipple. In case such an opening is made to allow the child to be nursed, it will be necessary to protect the nipple and areola by a pad of gauze inserted under the bandage.

Another form of bandage that may be used with very good results, especially in cases of infection of both breasts where nursing must be entirely stopped, is that recommended by the late Dr. P. A. Harris. It is a roller bandage, and its mode of application is somewhat difficult to describe, although quite easily understood when one sees it applied. This bandage might also be used to enclose only one breast. I will first describe its mode of application when only one breast is affected, and when the sound one is left exposed for the nursing of the child. A roller three inches wide, and from ten to twelve yards long, is required. Both breasts are covered with absorbent cotton, and a small pad of cotton to protect the shoulder is in readiness. Beginning outside of, and below the affected breast, the bandage is carried twice around the chest, passing first across the front, then it is carried under the affected breast, over the opposite shoulder, and again around the chest, once more under the affected breast, and the second time over the shoulder. Then it passes again under the breast, the lower half of which is now nearly covered, and around the chest above the sound breast. The next turn comes directly over the nipple of the inflamed breast, and above the sound breast. Two or three more turns, then cover the remainder of the affected breast. If any bandage remains, a firmer support to the breast will be given by making a turn again under the breast and over the shoulder, and still another under the affected breast, and above the healthy one, finishing with an extra turn over both breasts. The bandage must then be well fastened with from twelve to twenty safety pins placed in front, at back, and at the sides. The cotton over

the sound breast may be removed or an opening made to nurse the child.

When both breasts are to be enclosed, five or six yards more of bandage will be required. Begin with two turns around the body, and one turn under the first breast, and over the opposite shoulder as before. The bandage is then carried under the second breast, and over the back, across the shoulder opposite the second breast, down in front and under the breast again. Then it goes around the body, under the first breast, across the front part of the chest over the shoulder, under both breasts again and across the back, then over the shoulder opposite the second breast, and again under the second breast. This turn may be repeated the third time if necessary. Then the bandage is brought under the first breast, now nearly half covered, above the second breast, across the back, above the first breast and under the second breast, thus forming a figure of eight around the breasts. This may be repeated if necessary, and then the bandage is fastened with two turns of bandage around the chest over both breasts. This breast bandage must also be fastened with numerous pins. It is convenient to make the first turn with the patient on her back, and have her to sit while applying the rest. Much care should be taken in applying the bandage to make it just tight enough, and, on this account, the patient should be asked frequently if it is comfortable. If the bandage is too tight it may draw heavily upon the shoulders and become unbearable.

A very valuable adjuvant to the treatment of breast infection is the application of cold by means of the ice-bag. This not only has great influence in relieving the pain, but also modifies favorably the infective process. It can be applied satisfactorily only when the patient remains in bed. It is indeed desirable that the patient should always keep in bed for at least two or three days. The ice-bag is used in connection with the Y or circular bandage. The thick layer of cotton which is employed in connection with the roller bandage interferes with the action of the ice. The large-sized round bag is best. The ice should be broken quite fine, and the bag made to conform to the contour of the breast. If the infected lobe is on the outside, the bag is placed against the affected spot and supported by pillows or blankets. When the infected region is in the upper or inner side of the breast, the bag may be laid upon the chest.

Under this plan of treatment we shall find, in almost every case, that the pain has largely disappeared in twenty-four hours, and at the end of from forty-eight to seventy-two hours that the local tenderness has disappeared, and the nipple is healed. The ice may now be removed and nursing resumed, the child being allowed to stay at the breast not more than four or five minutes. If nursing increases the pain it must of course be stopped for one or two days more.

If, in spite of this treatment, some tenderness continues or reappears after a few days, and if suspicion of fluctuation exists, with perhaps a slight increase in tem-

perature, we must suspect the presence of pus. As was previously stated, this question can be easily and safely determined by the use of a proper hypodermic needle. If an abscess is present, however small, it should be opened at once. If we are in doubt as to the presence of an abscess, a continuance of the bandage support and the ice-bag can do no harm, and this is the best possible method of limiting the abscess formation and controlling the symptoms of pain and tenderness, until the diagnosis, and the need of an operation, can be definitely established.

Under the treatment of poultices, which was formerly so prevalent, it was frequently advised to allow the abscess to develop until a considerable portion of the breast was broken down before opening it. This unsurgical procedure resulted from the unfortunate experience that so many had had with the continued development of abscesses in the lobes surrounding those first attacked. The obstetrician could not assure his patient that one operation would be sufficient unless he waited until a very large abscess cavity was formed. The operation of opening an inflamed breast was very much dreaded; without an anæsthetic, it was very painful, and if an anæsthetic was used, a big operation requiring assistance was necessary. The method of infiltration anæsthesia has been of very great value to patients having abscesses of the breast, for by its use an abscess may be opened without pain, and so may be opened early. If a second or third abscess develops, it may likewise be attended to with little trouble and expense. The manner of using the infiltration anæsthesia is very simple. After a careful disinfection of the skin a few drops of Schleich's solution No. 2, applied with any ordinary hypodermic syringe that has been rendered aseptic, makes the short line of incision anæsthetic. After the incision, the pus is washed out with sterilized water, and a few sterile or iodoform threads are introduced for drainage. A strict antiseptic dressing is applied, and the breast bandaged very firmly. In twenty-four hours the drainage is removed. The wound is kept open by irrigation for a day or two longer, when it will generally close of itself.

By this management we shall not see the extensive destruction of the breast, the long-continued suppuration, the fistulæ, eczematous skin, worn-out mother, and puny child. If we come across these neglected cases we must, of course, treat them according to the rules of surgical procedure which apply to such cases. These rules are too well known to require any further description.

THE QUESTION OF OPERATION IN APPENDICITIS.*

By FORBES HAWKES, M. D.,

NEW YORK,

ADJUNCT PROFESSOR OF ANATOMY AND OPERATIVE SURGERY,
NEW YORK POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL;
ASSISTANT SURGEON, PRESBYTERIAN HOSPITAL; AT-
TENDING SURGEON, TRINITY HOSPITAL.

If we consider the question of operative intervention in appendicitis, we find that the opinions on the subject, both of the general practitioner and of the surgeon, have undergone many changes in the last few years, the over-radical surgeon and the over-cautious medical practitioner coming closer together in this time. Even at the present day, however, widely divergent views are held on this matter, so that the physician is very apt to call in consultation in his cases of appendicitis that surgeon whose opinions on the subject are entirely or nearly in accord with his own.

What cases of appendicitis demand operation? At what time of the disease shall we operate?

The opinions held on this subject may be briefly classified as follows:

I. Operate immediately; as soon, in fact, as the diagnosis is made, in each and every case of appendicitis.

II. Operate in all cases, except in those mild cases in which the patients are very distinctly recovering when first seen by the practitioner, and have no bad symptoms whatever at that time—and operate in these later, in the interval.

III. Let these mild cases wait for a second attack (which may never come).

IV. Wait for several attacks (three or more) before operating.

V. Do not operate at all unless alarming symptoms develop during an attack.

VI. Use medical treatment alone for all cases.

This last opinion is mentioned because every now and then reports are published of a certain number of cases treated in that way (by symptomatic treatment) with recovery, associated sometimes with perforation into the bowel, bladder, etc.

My own views are not the radical ones expressed in the first division, that is, to operate in each and every case of appendicitis on sight, but rather those expressed in the second, namely, that we should operate in all cases of acute appendicitis (and, roughly, within twelve hours; sometimes, of course, sooner), except in those cases of a mild type which exhibit no "bad signs or symptoms" whatever when first seen, and the patients are evidently recovering from their attack—and that we should operate in these cases later, in the interval.

To have this opinion well defined, it is necessary to indicate exactly what is meant by the expression "bad signs or symptoms." Briefly, these may be stated as follows:

A rectal temperature of over 102° F. A pulse of over 100 (if the patient is not distinctly neurotic or hysterical), or a *poor pulse* of any frequency whatever—and especially a pulse in which there is any *tension*. A thoracic respiration of over 34 (if the patient is not distinctly neurotic or hysterical). A sick appearance of the patient at any time. Continued vomiting at any time. More than moderate abdominal pain. More than slight rigidity. Any distention whatever. Marked sweating. A chill. The slightest dilated condition, not previously present, of the superficial abdominal veins on the right side of the umbilicus, or the slightest pitting of the skin in this region on pressure. Marked increase in frequency of micturition (indicating usually a long appendix reaching into the bladder region. Such an appendix will almost always be found markedly inflamed). The slightest jaundice. Constipation not relievable by enemata. Hiccough. A sudden drop of temperature or of pulse rate in a patient who has been sick for twenty-four hours or more (this usually means perforation with beginning general septic peritonitis). An increasing leucocytosis.

Any one of these signs or symptoms I consider "bad," and we should not wait till we get two or more of them, but the presence of any one of these should point the way. We may have a serious condition in or around the appendix revealed to us by only one of these signs or symptoms at first and for some time after, several being added later on in quick succession when the case is perhaps beyond our control. Many cases of general septic peritonitis have developed, as we all know, from the appendix as a starting point without an elevation of pulse rate or of temperature beyond the limits mentioned, and without other bad symptoms than a sick appearance of the patient. Many cases apparently mild will have a rapid pulse as the only indication of a severe grade of inflammation in a small area of the appendix, which may progress later to a perforation at that spot.

I hold firmly to the opinion, however, that in every acute case, except of the mild catarrhal type, we shall have at least one bad sign or symptom to put us on our guard if we examine the patient carefully. We may remove or advise removal, every now and then, of an appendix which we believe might possibly never have given trouble, or which might have been the seat of several attacks before a dangerous condition developed in it, but we should all feel, I am sure, that it is better that a few appendices of this kind should be removed while in this state than that a single gangrenous one should be taken out a little too late from a patient whose temperature was perhaps never above 102° F., whose pulse, of fair quality, was not over 90 at any time, and whose only bad symptom may have been marked rigidity on the right side until the symptoms of general septic peritonitis developed suddenly in their entirety. Numbers of such cases have been reported.

I have said that I advise operation in all acute cases except those mild ones that are first seen at a time when

*A paper read before the Lenox Medical and Surgical Society November 14, 1900.

the patients are very evidently recovering and there are no bad signs or symptoms whatever at that time. We are all aware that many mild cases, especially in the first attack, show during the first twelve hours symptoms out of all proportion to the lesion existing. Is there any way of ascertaining in each instance of this kind whether such a case will subside in twelve hours or so, or will go on to a critical condition in from twenty-four to thirty-six hours? I wish there were, for these are just the cases that one sees in private practice. The surgeon is called in early, nowadays, often within a few hours of the onset of the pain, and a "complex" of symptoms exists; advice is eagerly sought and much may depend upon it.

Suppose the advice is given to wait in such a case, in which the diagnosis of appendicitis is pretty sure. An ice-bag is applied to the right side, an enema given, and possibly a hypodermic injection of morphine. Five or six hours later, distinct improvement may be found, which progresses until complete recovery is reached. You congratulate yourself and your patient and think perhaps that after all it is just as well to have waited; recovery has followed this attack; there may never be another, and if the patient desires the appendix to be taken out, it can be done in the interval.

Suppose, however, that notwithstanding this distinct improvement, which starts in a few hours after you have seen your patient, you are called up in the early morning hours to find that the vomiting has started up again, the pain has distinctly increased, and your patient looks distinctly more sick than when first seen. You are again worried and seek a consultation; several hours are spent before you can get the surgeon you want, another hour or so is taken up in the preparation for the operation, and, when the peritonæum is opened, you may find a beginning general septic peritonitis, pus perhaps free around the appendix, the coils of intestine beginning to be injected and some lymph scattered over them, and your patient may either die or make a slow convalescence with an open wound for necessary drainage. Such cases occur every now and then, and, if we except the mild forms of catarrhal appendicitis, we can never be sure that any patient may not suddenly have these symptoms and run this course.

Will you satisfy yourself by saying that it was impossible to tell how things were going at the start? I hardly think so. Your patient's family certainly will not in these days of popular knowledge on the subject, and you are lucky if you escape their censure for not advising an immediate operation in the case, when you were first called. My own practice, therefore, in these cases, when I see them for the first time in the first few hours while the acute symptoms are present, is always to advise operation immediately and to have the patient or the family accept the responsibility of nonintervention themselves, if that is their decision, after explaining matters to them.

If I see a similar case, however, for the first time after every one of these so-called "bad symptoms" has entirely

subsided (usually from twelve to twenty-four hours after onset in a case that is going to do well), I am then willing to let such a patient go on to recovery without operation, having a leucocyte count made at intervals, and watching the condition very closely with a careful nurse who will report any change in any of the symptoms or signs immediately, so that the appendix may be got at within a few hours of the possible onset of any bad symptom. I have personally never lost a case by doing this, where every one of these bad symptoms had entirely subsided, nor have I seen such a case, after the entire subsidence of every bad symptom, go wrong and require immediate operation. I affirm that in every case where a dangerous condition exists there will be some one bad sign or symptom at least to guide us; there may be but one, but this one should be enough.

Should every patient with appendicitis that has recovered from a first attack be operated on before a possible second, or should we advise waiting for this second attack before operating?

My own opinion used to be that, if the patient stayed within easy access of a good surgeon, it was allowable to wait for a second attack that might never come. This precluded, however, any travelling, except along the beaten paths and the larger cities. Travelling in Europe was interdicted on account of the views held in the past by many there on this subject. My experience with several such cases in the last few years has led me to change my views, and I now advise all patients who have had a distinct attack of appendicitis to have the organ removed before a possible or probable second attack. I have seen perforation occur within twenty-four hours of the onset of a patient's second attack, and I prefer that the responsibility of carrying around a once inflamed appendix with its possibilities should be shouldered by the patient if he prefers to wait; I always state that it is impossible to know the exact condition in which the inflammation has left the appendix, and that, while a certain number (twenty-three per cent.) of patients never have any trouble or any second attack afterward, others, and the majority (seventy-seven per cent.), do have recurrences, and that any one of these recurrences may be distinctly dangerous, possibly fatal, even with quick operation.

Should the patient be the subject of distinct cardiac, renal, pulmonary, or tuberculous disease, or be handicapped by the presence of much fatty deposit about the abdomen, the dangers of a general anæsthetic should be considered and advice given accordingly.

We were formerly justified, in some cases, in allowing a second attack to manifest itself before operation, for the danger of another possible or probable attack could very properly be balanced in the surgeon's or practitioner's mind against a not unheard-of postoperative sepsis or a possible hernia or both. But now that we do practically all our abdominal work either with sterile rubber gloves or with hands as aseptic as the human skin can be made, and have at our disposal the more than excellent

intermuscular method of Dr. McBurney, we are getting far different results, and are justified, in my opinion, in shaping our practice according to the opinions laid down in this paper. It comes down to this: Does a patient run a greater risk of a possible postoperative sepsis* or of a probable second attack with possible early pus formation, or gangrene with perforation and general septic peritonitis?

The old idea about there being a time in the course of an appendicitis attack when operative procedures were in themselves more dangerous, and more likely to spread the infection than to curtail it, has been thoroughly proved to be an erroneous one in every way. It was not the time in the course of the attack that made the difference, but the operator's methods in these cases. These have been perfected, and the danger recognized to be where it really is, due allowance being made for the various grades of infection as seen by the cultures obtained from many cases. There is no time in an appendicitis attack when operation is contraindicated *per se*. When we are brought face to face with alarming symptoms of appendicitis in a patient suffering from marked cardiac, pulmonary, renal, tuberculous, or other disease, and are loath to use a general anæsthetic, we have at our disposal our sterilizable β eucaine solutions. Under them the discomfort is comparatively slight in my experience.

I am not referring, of course, in what I have said to those not infrequent cases where the diagnosis is in doubt. These naturally stand apart, the diagnosis being at times impossible early in the trouble; this may happen on account of the location of the pain, which may be felt in another part of the abdomen at first, before it has localized itself to the right iliac fossa. In others, it is hard to distinguish between appendicitis, some forms of cholecystitis, and biliary calculi associated possibly with a movable right kidney; in still others, the distinction between an inflammatory condition in a dependent appendix and that in the right ovary and tube, and occasionally in the bladder, may be hard to make until we have watched the case for a while. These conditions are apparently fraught with less danger at the start; on this account we should keep the possibility of the more dangerous condition before us continually, until we feel confident that we have ruled out the appendix in any doubtful case. Clinically, the association of appendicitis with one or more of these previously mentioned lesions is very frequent.

A mass in the right iliac fossa, following or developing during an attack of appendicitis, should always be opened as soon as possible. While such a mass is usually found to be an abscess, it may prove to be made up in part or entirely of rolled-up and adherent omentum, the appendix being at or near the centre. If so, the contained appendix has in every case that I have seen been markedly diseased and fit for removal.

*Personally I have not lost an interval case or obtained wound infection in any of these cases beyond a drop or two of pus around a skin suture (and this latter was before the rubber glove period).

While many a pyosalpinx may be found sterile by the cultures, an appendix abscess is practically never so (that is, I have not seen a report of such a case), and while the rupture of such an appendix abscess into one of the hollow viscera, intestine or bladder, has been followed in some cases, it is stated, by permanent recovery, all agree that it is unwise to have a patient run the risks attendant upon a recovery by this route.

As to the length of time that it is safe to wait after an attack has subsided, before operating in the interval, my own preference is for not more than ten days after the pulse and temperature have apparently reached normal. It is rare to have another attack within two weeks after the complete subsidence of all symptoms. They will, however, recur occasionally in two or three weeks.

Another reason for not waiting much longer is that it is possible for an attack to subside entirely, so far as symptoms are concerned, leaving a small localized pus collection in or adjacent to the appendix; a distinct danger which cannot be foretold. That the patient should be made to assume the responsibility of a nonintervention, after a calm and impartial *exposé* on the part of his physician of the dangers which may attend the carrying around of a once inflamed appendix, I consider perfectly proper and wise, and while I never persistently urge patients who have had only one mild attack of catarrhal appendicitis to have the organ removed, I do distinctly advise them to do so unless there are offsetting contraindications in the way of renal, cardiac, pulmonary, tuberculous, or other disease.

We all know that hospital patients, that is, the usual run of ward patients, have to be dealt with somewhat differently from one's private patients. It is certainly a good plan to operate on all such cases of appendicitis (unless some of the previously mentioned contraindications are present), soon after admission, at any rate. The mild cases rarely enter the hospital wards, and even in these the degree of intelligence exhibited by the patients usually precludes their proper understanding of the conditions liable to arise, if they are allowed to take their once inflamed appendices home with them in their abdomen.

As to the non-surgical treatment of those mild cases of catarrhal appendicitis which are first seen when they are very evidently recovering without any bad symptoms whatever, I would say that my own practice has simply been: Ice bag to the right iliac region, enemata for the bowels, fluid diet without milk, total abstinence from opium in any form, and the use of the rectal tube for gas formation.

Personally, I prefer not to give any calomel (except in the general septic peritonitis cases, after operation) for fear of over-action. That enemata are sufficient to clear out the large intestine, has been proved to my satisfaction, for I have never been able in such cases, after opening the peritonæum, to feel any fæcal matter whatever, in either the caput coli or the large intestine. And

in the other cases that are about to be operated on, the therapeutic measures employed while waiting for the operation have been: Washing out the stomach for persistent vomiting; morphine hypodermatically for the pain; rhythmical tongue traction (Laborde's method) for hic-cough; cold coil over the abdomen and rectal tube for gas distention; strychnine hypodermatically, with or without atropine, and hot-water colon irrigation, as heart stimulants; copious rectal enemata for the constipation.

The more cases of appendicitis one sees, the more conservative one becomes, but I am here using the word conservative in its proper sense, as opposed to that turn of mind which allows patients to drift along in a channel where soundings are impossible, and where at any time, suddenly and with little or no warning, the rocks may be struck and a total wreck result; for I maintain that, by following out the rules herein mentioned, the careful and painstaking surgeon will without question "conserve," that is, "save" more of his appendicitis patients than by any other method with which I am acquainted.

That, in the course of years, a few appendices will have been removed that might never have given further trouble is quite true, but it is even more true that a certain number of patients will be saved from abdominal suppuration or from perforation with a rapidly developing general septic peritonitis.

42 EAST TWENTY-SIXTH STREET.

THE GENERAL PRINCIPLES OF INFANT FEEDING, WITH A SIMPLE METHOD OF HOME MODIFICATION OF COW'S MILK.*

BY L. EMMETT HOLT, M. D.,

NEW YORK.

THE nutrition of infants is easy only on paper. At the bedside or in the nursery, even when conditions are simplest, nutrition is successfully carried on only by care and constant watchfulness. At times it becomes one of the most difficult problems in medicine. All methods of feeding have their successes and all have their failures. What we want to know is the best method of feeding most infants.

Maternal nursing, as now carried on, has as large a proportion of failures chargeable to its account as any method with which I am familiar. The proportion of successes among women of the better class in New York is, in my experience, hardly twenty per cent. Wet-nursing also, as it is, can hardly be considered to boast of much better results. It is usually my fortune to have three or four, and sometimes ten or twelve, failures with different women before a suitable one is found. Let us bear these facts in mind when we think of the difficulties and failures with artificial or substitute feeding.

When properly begun and intelligently continued,

artificial feeding with the average child I believe to be more successful than the two other methods mentioned, as they are usually carried on. When improperly begun and ignorantly carried on, it is the cause of more deaths than all the contagious diseases combined. Not that I would discourage maternal nursing; by all means should every effort in that direction be seconded by the physician; but at the same time we must insist that all such cases be watched with the closest attention, in order to determine at the earliest possible moment whether such nursing is advantageous, and, if not, to discontinue and begin with something better before the digestive organs have been seriously upset or so much weight has been lost that grave malnutrition exists.

We may assume without discussion the truth of certain propositions:

1. That good breast milk not only is the best food, it is the ideal food; all substitutes must resemble it in furnishing certain proportions of fat, sugar, proteids, and salts which Nature has ordained to be the requirements in the young infant for normal development.

2. That the nearest approach to these elements is found in fresh cow's milk.

3. That, although containing all the elements needed, they are not in cow's milk furnished in their proper proportions; furthermore, that the elements themselves are not identical in their composition with those of breast milk; and therefore that cow's milk cannot be fed to most infants without some modification.

Fresh cow's milk, properly modified, nearly the whole scientific world to-day agrees to be our best substitute for the breast. The main question for discussion, then, is, What constitutes proper modification, and how can it be most easily accomplished? We sometimes speak of modified milk as if it were a new thing, but the late product is only the evolution of a very old idea. The earliest milk modification was simply dilution with water and the addition of cane sugar to make it taste like breast milk. Later, when the composition of breast milk came to be better understood, it was thought that all that was necessary in a modified milk was to secure the same proportions of fat, sugar, and proteids as existed in breast milk, and we should then have the best possible substitute, a food suited to the great majority of healthy infants. Out of this idea grew the various mixtures of milk, cream, sugar, etc., which aimed to reproduce, according to the views of different writers, the most exact breast-milk proportions. This represented a great advance, in that some proper relation between the different food constituents was maintained; and, while such formulas succeeded admirably with many infants, they failed with many more. Although the food was the same, the child was not always the same. Again, the difference in the digestibility of some of the elements, especially the proteids, was not sufficiently taken into account. Experience has shown that no single formula can be made to do general duty. Careful students of the problem have

*Read before the New York Academy of Medicine, October 18, 1900.

stopped trying to discover a *food*, and gradually there has been evolved in the place of it a *method of feeding* known in this country as the percentage method. The central thought of this is to consider the different elements of the milk separately, and to adapt their proportions in the food to the digestion of the child. In other words, it aims to discover the proper proportions of fat, sugar, and proteids and the best method of gradational increase for healthy infants with normal digestion; and for those with abnormal or feeble digestion, the combinations best suited to the individual conditions. Where difficulty is found in the digestion of cow's milk, instead of discarding it and turning to proprietary substitutes of the manufacturer, the aim is to try to discover with which of the elements of cow's milk the difficulty lies, and to modify our proportions accordingly until those best suited to the existing condition are secured. Milk indigestion is not one thing; sometimes it is fat indigestion, in other cases proteid indigestion, and in still others sugar indigestion. By the modern method of feeding, an attempt is made to separate these conditions, and, instead of treating them all in the same way, by simply diluting the food and thus reducing the proportions of all of the elements, the aim is to reduce only the one that is causing the trouble.

Such is the theory upon which the modern modification of milk is based; somewhat more complex possibly than the method it has superseded, but not nearly so much so as might at first appear. In practical results, however, it is a very great step in advance, in the opinion of nearly every one who has taken the trouble to master the method. The percentages are simply a method of statement of what we do. At first it may be somewhat difficult to think in percentages, but with a little study this is easily mastered, and it is the only scientific and accurate way yet proposed of recording our observations for the guidance of others and for a comparison of results with them.

To the milk laboratories the medical profession owes the development of this principle of feeding. They have taught us to approach the problem from what, to my mind, is the only scientific standpoint, working not for the discovery of the food, but for the elaboration of a correct principle of feeding, based upon accuracy and definiteness, without which all is chaos, confusion, and haphazard experimentation. By this I do not wish to imply that we have solved this difficult and perplexing problem. What I do mean to say is that we have made a beginning, and if this problem is ever entirely solved I believe it will be by working along the lines upon which we have now begun.

I shall not now consider the milk laboratories in their relation to the modern method of feeding, but will say only this regarding them, that I believe in the milk laboratories, and that during the past few years I have fed 215 infants, including two of my own, on modified milk prepared by them. My results have steadily improved as with increased experience I have learned better and better

how to prescribe milk. The purpose of the present paper, however, is to consider how the main advantages of the laboratory method may be secured when milk is prepared by the mother or nurse. There are four essentials to success in infant feeding with milk modified at home:

1. The best raw materials, the cleanest and freshest milk and from healthy cows.

2. Intelligent and careful cooperation on the part of the mother or nurse.

3. Definite and minute directions, generally in writing, of exactly how the food is to be prepared, the quantity for each feeding, the hours of feeding, etc.

4. The physician must see that what he orders is carried out. In order to do this, occasional visits must be made to the child and every detail of nursery routine carefully scrutinized. Regular reports should be rendered, at least once a week, of the child's progress as to weight, condition of its appetite, stools, digestion, etc.

I believe that it is the physician's prerogative to direct in the matter of feeding. Too long has this responsibility been assumed by ignorant nurses and inexperienced mothers, whose only guide in many cases has been the advice of friends or the circulars of the proprietary food manufacturers, with what disastrous results to life and health is well known. If the physician assumes to direct, he must himself give more time and attention, even in minute details, to the subject than he has hitherto done. The continued complaint of patients is the attitude of indifference of most physicians to these details of infant feeding; but there is no success to be had without them. One can never prescribe a food and turn the case loose; but week by week the progress must be watched and such changes made as are demanded by the conditions which arise.

In practice we must separate normal cases, or those of healthy infants with average digestion, from the abnormal cases or those in which there is feeble digestion or more or less of indigestion. From the failure to make this distinction much confusion on the subject has arisen and many errors have crept into the subject of infant feeding. The digestion of all healthy infants is very much alike, and they may be fed in pretty much the same way; but the indigestions of unhealthy infants are endless in their variations and each one must be considered by itself. If it is only healthy infants that can be fed by rule, it is also true that, if fed from the start according to proper rules, most infants will remain healthy. It is not difficult to start right, and not very difficult with a little intelligent care to keep right, but it is exceedingly difficult when things have been going wrong to get right. In a nutshell, directions as to the right method of beginning are very simple: viz., to start with such low proportions of fat and proteids, particularly the latter, that the child's digestion is not upset; and, as soon as it has become somewhat accustomed to the food, to gradually increase the proportions of these elements. This is necessary for

the reason that the stomach of the infant was not intended to digest cow's milk, but breast milk; yet, if rightly managed, the organs of the average infant can in the great majority of cases be trained to digest a properly prepared cow's milk perfectly well.

In the home modification of milk there are two distinct problems: 1. To get the required proportions. 2. To use them after we have them. The latter is by far the more difficult. No plan of home modification yet proposed secures more than approximate accuracy in the percentages of fat, sugar, proteids, etc. Yet, if directions are carefully carried out, a degree of accuracy which is sufficient for all practical purposes can be secured. The thing desired is a method simple enough to be readily grasped by the average mother or nurse who is to carry out the physician's directions. The method here given is one which in principle I have followed for many years, and I have found no difficulty in making nurses understand how to use it.

While it is not ordinarily possible to know the exact composition, it is essential that the physician should know the approximate composition of the milk, cream, etc., ordinarily used in the home; and also that he should know how to obtain most easily the elements from which the various milk modifications are derived.

The composition of herd-milk, or the mixed milk of a number of cows, is practically constant except in the proportion of fat, this varying from 3.50 to 5.50 per cent.; in the ordinary samples used, 4 per cent. may perhaps be taken as the average, except in milk from Jersey cows. As regards the proteids, it seems certain from recent analyses that to assume 4 per cent. as the average is a mistake, and that 3.50 per cent. is much nearer the truth. Some of the foreign authorities place it as low as 3.40 per cent.; others at 3.60 or 3.70 per cent. The sugar is not far from 4.30 to 4.50 per cent. We shall therefore assume in our discussion the composition of average herd-milk to be: Fat 4, sugar 4.50, proteids 3.50 per cent.

It is necessary to know also the percentages of sugar and proteids which are present in cream containing different amounts of fat. The following table, taken from the analyses made by Adriance and others, may, I think, be assumed to represent pretty nearly the composition of creams of different density:

	I.	II.	III.	IV.	V.
Fat.	4.00	8.00	12.00	16.00	20.00
Sugar.	4.50	4.35	4.20	4.05	3.90
Proteids.	3.50	3.40	3.30	3.20	3.05
Salts.75	.70	.65	.60	.55

In most of the modifications of milk for young infants, it is required that the fat be considerably higher than the proteids. A simple plan would seem to be, first, to raise the percentage of fat to such a point that, when the milk is diluted to bring the proteids down to the required figure, the fat shall also be reduced to the percentage which we wish to use. Really, the important part of the modification consists in finding the best way of introducing the extra fat desired. It may be done by the

addition of cream or by using the *upper milk* after it has been standing for a given length of time.

If cow's milk from a mixed herd is put into bottles soon after it is drawn and rapidly cooled, it will be found that after four hours the upper fourth will contain nearly all the fat that will rise as cream, and that the upper layers will have nearly the same percentage of fat whether the milk has stood for four hours, for eight hours, or over night. This has been demonstrated in a series of experiments made for me by Messrs. Upton & Jeffers, at the Walker-Gordon Farm at Plainsboro. After it had been standing under the conditions mentioned, fat-tests were made with the Babcock apparatus of the different four-ounce layers of bottled milk, which were carefully removed with a siphon, with the following results:

	After 4 Hours, Per cent. of fat.	After 8 Hours, Per cent. of fat.	Over Night, Per cent. of fat.
Upper 4 oz. . . .	20.50	21.25	22.00
Second 4 oz. . .	6.00	6.50	6.50
Third 4 oz. . . .	1.50	1.40	1.00
Fourth 4 oz. . .	1.20	1.00	.30
Fifth 4 oz. . . .	1.00	1.00	.05

Each of these percentages represents the averages, each test having been repeated many times, 110 different tests having in all been made. It will be seen from this that after four hours the composition of the separate layers does not change very much with the period of standing. With this knowledge of the amount of fat in the different layers of milk, it becomes a comparatively simple matter to secure almost any desired percentage of fat by simply varying the number of ounces removed from the upper part of the quart. Thus, with the milk in question it will be seen that by removing

16 oz., or upper 1-2,	we secure approximately 7 per cent. of fat.
11 oz., " " 1-3,	" " " " 10 " " " "
8 oz., " " 1-4,	" " " " 13 " " " "
6 oz., " " 1-5,	" " " " 16 " " " "

The formula in each case with this milk runs slightly above the percentages given; but, as the particular milk with which the tests were made averages about 4.25 per cent. of fat, it may be assumed that these figures represent very nearly what is obtained when the 4.00-per cent. milk is used, this being what the average physician is likely to have at hand.

Instead of this milk, if Jersey milk (5.00 to 5.50 per cent. of fat) is used, from two to three ounces more may be removed of each formula. If a poor quality of milk (3.00 to 3.50 per cent. of fat), about two ounces less than the amount specified should be taken to secure the correct percentages of fat.

For all who use milk fresh from the cow, the simplest plan is, therefore, to put that which is needed for the baby into a glass quart jar or quart milk-bottle, placing the jar, covered, in ice water and letting it stand for at least four hours, after which the upper portion may be removed. The same plan can be followed and essentially the same result will be obtained when the milk has stood for eight hours, or with the usual bottled milk sold in cities and delivered on the following morning, always

provided the bottling has been done at the dairy before the cream has been allowed to rise. This upper milk should be removed with a siphon, spoon, or cream-dipper, but should not be poured off.

We have now obtained five different grades of milk having different fat percentages in which the fat is respectively five, four, three times, and twice the proteids, and in which the two are about equal. The composition of these milks in fat, proteids, and sugar is as follows:

Per cent.		Per cent.	
Fat to proteids	5 : 1 = 16	milk = fat	16. sugar 4.05 proteids 3.20
" " "	4 : 1 = 13	" = "	13. " 4.15 " 3.25
" " "	3 : 1 = 10	" = "	10. " 4.30 " 3.30
" " "	2 : 1 = 7	" = "	7. " 4.40 " 3.40
" " "	8 : 7 = 4	" = "	4. " 4.50 " 3.50

Instead of using the upper layers of bottled milk after standing, these formulas may be obtained by mixing milk and cream as follows:

The 16-per-cent. milk is the ordinary gravity cream.

The 13-per-cent. milk is obtained by mixing 1 part of milk with 3 parts of (16 per cent.) cream.

The 10-per-cent. milk is obtained by mixing 1 part of milk with 1 part of (16 per cent.) cream.

The 7-per-cent. milk is obtained by mixing 3 parts of milk with 1 part of (16 per cent.) cream.

The 4-per-cent. milk is ordinary plain milk.

These calculations have been given somewhat in detail to show how from the materials which are generally available in the home, milk fresh from the cow, bottled milk, or milk and cream, we may easily obtain milks containing a definite percentage of fat, *i. e.*, 4, 7, 10, 13, and 16 per cent., which we wish to use in our modification. These milks have been called by different names, such as "definite-percentage milk," "top milk," "superfatted milk," etc. I shall hereafter refer to them as *primary formulas* of the different series. Once the primary formula is obtained, the subsequent modifications become a comparatively simple matter.

Modification of the Fat and Proteids.—Given the primary formula in which the ratio between the fat and proteids desired is known, we may, by a process of simple dilution, derive as many secondary formulas as we wish, the ratio between the fat and proteids being of course unchanged. We may make the constant difference between the formulas as large or as small as we desire. For convenience in calculation it is easy to make this constant difference $\frac{1}{20}$ of the original formula.

Modification of the Sugar.—The range required in the modification of the milk sugar is ordinarily between 5 and 7 per cent. In estimating the quantity to be added to bring up the proportion to this amount, account must of course be taken of the sugar already present in the milk. I have found that, except for mixtures which have proteids above 2 per cent., *i. e.*, those which are more than half milk, one ounce of sugar to twenty ounces of the mixture will give very nearly the percentage required, viz., about 5 per cent. for the lower mixtures and 6.5 or 7 per cent. for the higher ones. This embraces nearly all the formulas required for the first ten months; after this

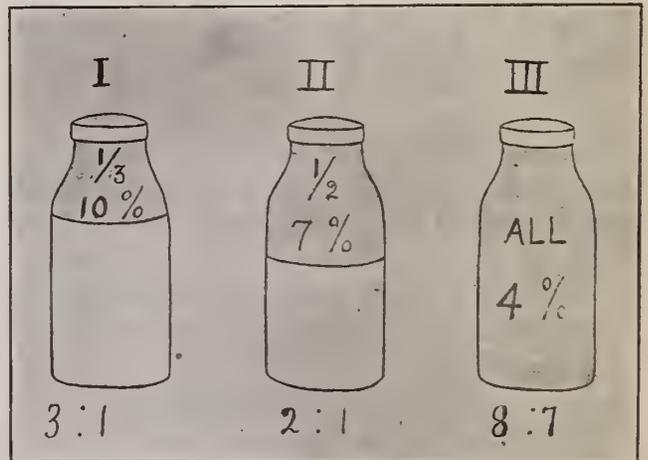

the close percentages are not so important. The amount of sugar in the primary formulas varies between 4.05 and 4.50 per cent. A mixture, for example, which contains $\frac{4}{20}$ of any primary formula will have, before any sugar has been added, .80 or .90 per cent. of sugar. If one ounce of sugar is now added to each twenty ounces of the mixture, it will now be raised to 5.8 or 5.9 per cent., according to which primary formula we use. In practice this may be considered as a 6-per-cent. sugar.

In measuring the milk sugar it is to be remembered that one ounce by volume is very nearly one ounce by weight. If the measuring is done with the tablespoon, one even tablespoonful may be calculated as three drachms, or two and a half even tablespoonfuls as one ounce. If cane sugar is used, the proportion should be about one half that which has been mentioned, *i. e.*, half an ounce to each twenty-ounce mixture, as there are few infants who will bear cane sugar in the proportion of 5 to 7 per cent. in their food.

Lime Water.—It is generally agreed that 5 per cent. of lime water produces the average alkalinity required. This is easily secured by adding one ounce of lime water to each twenty-ounce mixture. It can readily be increased when desired.

Diluent.—For my own part, I prefer boiled water as a diluent for the first months of life. But the method of modification is not affected if anything else is used. One may, if he prefers, use one half or one quarter barley water, or the dilution may be entirely with this. The sugar is, of course, to be dissolved in the diluent, whatever it may be. In all the formulas given, the water or other diluent is to be added in a sufficient quantity to make up twenty ounces, this unit being the most convenient one for calculation.

The foregoing detailed description of the different

steps of the modification may seem rather complex. However, the practical application of the results is very simple.

The three series of formulas which are most used are: 1. Those in which the fat is three times the proteids. 2. Those in which the fat is twice the proteids. 3. Those in which they are about equal. With these three the

great majority of healthy infants can be fed during the entire first year. The primary formulas from which the three series are severally derived are graphically shown in the accompanying illustration.

I have written out below a number of formulas derived from these primary ones, showing how easy it is to pass from a weaker to a stronger formula. Those given are the combinations which I have found more generally useful in my own practice. Many others may, of course, be derived in each group, but the proportion of fat to proteids will always remain the same as in the primary formula:

SERIES A.—Ratio of fat to proteids, 3 : 1.

Primary Formula.—10 per cent. milk; fat 10, sugar 4.30, proteids 3.30 per cent. Obtained (1) as upper one third of bottled milk, or (2) equal parts of milk (4 per cent.) and cream (16 per cent.).

Derived Formulas Giving Quantities for Twenty-ounce Mixtures.

Milk sugar. 1 oz.
Lime water. 1 oz.
Water, q. s. to. 20 oz.

I.

I.	With 1 oz. of 10% milk	= fat .50	sugar 5.20	proteids .17%
II.	" 2 oz. " 10% "	" = " 1.00	" 5.40	" .33%
III.	" 3 oz. " 10% "	" = " 1.50	" 5.60	" .50%
IV.	" 4 oz. " 10% "	" = " 2.00	" 5.85	" .66%
V.	" 5 oz. " 10% "	" = " 2.50	" 6.05	" .83%
VI.	" 6 oz. " 10% "	" = " 3.00	" 6.25	" 1.00%
VII.	" 7 oz. " 10% "	" = " 3.50	" 6.50	" 1.20%

If more than twenty ounces is needed, it is convenient to calculate the quantity as 25, 30, 35, 40 ounces, etc.; thus, using No. IV, we would have:

10-per-cent. milk. 4 oz.
Milk sugar. 1 oz.
Lime water. 1 oz.
Water, q. s. to. 20 oz.

II.

To make 25 oz. add ¼ more.	To make 30 oz. add ½ more.
10-per-cent. milk. 5 oz.	10-per-cent. milk. 6 oz.
Milk sugar. 1½ oz.	Milk sugar. 1½ oz.
Lime water. 1½ oz.	Lime water. 1½ oz.
Water, q. s. to. 25 oz.	Water, q. s. to. 30 oz.

SERIES B.—Ratio of fat to proteids, 2 : 1.

Primary Formula.—7 per cent. milk; fat 7, sugar 4.40, proteids 3.40 per cent. Obtained (1) by using the upper one half of bottled milk, or (2) by using three parts milk (4 per cent.) and one part cream (16 per cent.).

Derived Formulas Giving Quantities for Twenty-ounce Mixtures.

Milk sugar. 1 oz.
Lime water. 1 oz.
Water, q. s. to. 20 oz.

III.

VIII.	" 16 oz. " 4% "	" = " 3.20	" *8.50	" 2.80%

Formulas marked with an asterisk in the last two series are the only ones in which a special calculation of the sugar needs to be made. The usual amount (1 ounce to 20-ounce mixture) gives, as is seen, too high a percentage. It is seldom that infants taking the high percentages of fat and proteids of these formulas require the sugar to be even as high as 7 per cent. For the average case a good rule is to add only three quarters of an ounce of sugar to each twenty ounces for formulas containing from one half to three fourths milk, and more than that, only one half ounce to each twenty ounces.

A fourth series may be derived in a manner exactly similar to the foregoing, but using as a primary formula a 13-per-cent. milk obtained as already described. In this series the ratio of the fat to the proteids will constantly be 4 : 1.

A fifth series may be derived using the 16-per-cent. milk (cream) as the primary formula. In this the fat will be to the proteids in all the derived formulas as 5 : 1.

Such an array of figures as those given above may appear formidable to one not very familiar with the percentage method of describing a food. With closer acquaintance I do not think they will be found so. Many of these are ordinary modifications in daily use by most physicians. The percentages, however, form a useful means of statement of exactly what we are giving.

Application of These Formulas to Infant Feeding.—

We come now to the second and more difficult part of our subject, viz., how to use the formulas we have obtained. The first year may be divided into three feeding periods. The first one extends from birth to the end of the third or fourth month; the second from the end of the third or fourth month to about the end of the tenth month; the third comprises the remainder of the first year. For the first period the best results in my experience have been obtained when the proteids are three times the fat, or the ratio existing in good breast milk; for the second period when the proteids are twice the fat; and for the third period when the two are nearly equal.

With the newly born child I ordinarily begin with No. II of Series A, fat 1.00, sugar 5.40, proteids .33 per cent. The strength of the food is gradually increased up to No. VI, fat 3.00, sugar 6.25, proteids 1.00 per cent.

This is usually reached by the sixth or seventh week. From this time it is generally desirable to increase the fat more slowly so that the food is strengthened mainly in the proteids. When this is required we pass to Series B, in which the fat is nearly twice the proteids, and begin with No. VII, or No. VIII. After this time the increase in strength is made more slowly. With Nos. IX, X, and XI we can progress very well until the ninth month, the quantity only being increased with the demands of the child. After this the proteids are further increased by passing to Series C. We may begin with No. VI or No. VII, from which the child is gradually shifted to whole milk.

The combinations of low fats and low proteids are found in the first three or four formulas of Series B and C. These combinations are useful for some infants during the early months who have particular trouble with the digestion of the fat, and with many at a later period who suffer from fat indigestion.

The formulas containing relatively high fats and low proteids have not been written out in full, but they may readily be derived from the 13- or 16-per-cent milk in which the fat is respectively four times or five times the proteids. Such combinations are sometimes useful in the early months with infants who have particular trouble with the proteids, but who are able at the same time to take a relatively high fat. Such proportions are not generally advisable except for short periods, and for the great majority they are not nearly so useful as the derivatives of 10-per-cent. milk in which the fat is three times the proteids.

No schedule can be followed with absolute regularity. To follow any one too closely is to violate the central principle of percentage feeding, which is to adapt the milk to the child's digestion at the time. A schedule is to be looked upon rather as a general guide showing the method according to which the gradations of the food may best be made in health. It represents the proportions which in my experience have succeeded best with average children of normal digestion.

The principles underlying this schedule must be understood if it is to be rightly applied. In Series A the ratio of fat and proteids is that of breast milk, i. e., three to one. I think I have obtained better results with most cases by maintaining this ratio during the early months, reducing the fat as well as the proteids to low figures during the early weeks. We must start with low percentages, and I believe that 1 per cent. of fat and 0.33 per cent. of proteids are not too low for the first days of life. The next point is the gradual increase; at first this is made every few days, as the child becomes accustomed to cow's milk and has power to digest it, the increase always being very carefully made lest we go ahead so fast that we derange the functions of digestion, after which all progress is difficult. The usual indications for an increase are an unsatisfied child who is digesting well. The rapidity with which the percentages are raised will thus

vary much with different children; but the gradational steps of the increase may be advantageously followed with nearly all.

Except to start with too high a percentage of proteids, no greater mistake can be made in infant feeding than to continue long with a low percentage of proteids. Every day we see infants pale, anæmic, and exhibiting all the signs of malnutrition who have been kept too long on a low percentage of proteids, often 0.5 per cent., until they are three or four months old, or 1 per cent. until eight or nine months old. This in most cases is a serious mistake. We increase the power of digestion by gradually increasing the work the organs are given to do, not by giving them hardly any work to do. In effect the latter is like the continued use of predigested foods. Because of the slight discomfort or disturbance which is apt to follow an increase in the proteids, the physician is oftentimes inclined to go back to the weaker formula; while, if the stronger is continued, the child very soon becomes accustomed to it and quite equal to digesting it; the only essential is that the increase is not made too rapidly. Properly managed, the organs of an average infant can be trained to digest 1.5 per cent. proteids at the end of three months and 2 per cent. at five or six months.

During the first two or three weeks progress in infant feeding is not best measured by the scales. While the child is upon the low percentages advised, it is seldom that any material gain in weight occurs. However, if there is no vomiting or colic, if the child is comfortable and sleeps most of the time, and if the stools are gradually assuming a healthy color and normal odor, conditions may be considered to be entirely satisfactory. The food can be steadily strengthened with the demands of the child's appetite, and soon the increase in weight will begin, and when once begun it will be continuous. But nothing is easier than to derange the organs during the first weeks by too high percentages, and such disturbances, even though they appear trivial, often continue for many weeks.

I have dwelt so long on the first weeks for the reason that everything depends upon them. Close attention until the child is well started, and subsequent progress is a simple matter. Nothing has been said about quantity and frequency of feeding, not because these are unimportant, but these matters are fully considered in most of the recent books, whose schedules in general may be followed.

After weaning, or in the case of a child who has previously had no cow's milk, one must begin, even in the case of one who seems quite well, with percentages considerably lower than the age and weight would seem to demand. At three months it is better to begin with the proportions ordinarily taken by a bottle-fed infant at three weeks; or at nine months, with those usually taken by one of two or three months; making the increase in strength just as rapidly as the condition of the digestive organ warrants.

Where changes in diet are made, as in most cases they are, because the child is not thriving or has some evident symptom of indigestion, it is often difficult to know where in the schedule to begin. In such cases we must get out of our minds the notion that food can be ordered by the child's age or even by its weight, although both must be taken into account. The essential thing is the condition of the digestive organs, and, unless this is carefully considered, failure is almost inevitable. To decide as to percentages, one must know, besides the age and weight, the previous gain or loss, character and quantity of the food which has been taken, the appetite, the number and nature of the stools, and also whether any such symptoms are present as vomiting or regurgitation, colic, constipation, fretfulness, discomfort, or disturbed sleep. Nothing but personal experience will enable one to judge aright as to the combinations best suited to the existing conditions. In any case the first prescription must be an experiment. It is always wise to begin with low percentages and watch the result, making subsequent changes according to symptoms.

Conditions are often present in the individual child which may make particular modifications necessary. I will mention only a few of the most prominent ones. The most troublesome one probably with physicians generally is constipation. In the early weeks, while they are taking the low percentages advised, constipation is not infrequently present, and is simply due to the small food residue, owing to the low total solids in the milk. Unless, however, this produces a great deal of discomfort, it seems to me better to disregard it, particularly if the color and odor of the discharges are nearly normal. By gradually raising the proportions of fat and proteids along the general lines of the schedule, in nearly all cases these symptoms soon pass away, while if drugs are used or, worse, if the fat is rapidly increased, there usually results a disturbance of both gastric and intestinal functions which often ends in greatly increasing the constipation instead of improving it. Personally, I have found that anything higher than 3 per cent. of fat during the first six or eight weeks almost always works badly, and that over 4 per cent., at any time during the first year, can seldom be long continued without disturbing the digestion. I am confident that in using modified milk from the laboratories a great deal of the indigestion which has been seen has been due to too high fat percentages ordered, especially in hot weather.

Habitual vomiting or regurgitation is almost always due to excess of fat; if not to this, to excess in quantity. For an infant with such symptoms one should never begin with any formula in which the fat is more than twice the proteids, and often equal percentages are better.

Habitual colic is nearly always from an excess of proteids. For such a condition one should not give more than one third as much proteids as fat, and usually at first low percentages like those of the first series of formulas. This condition is usually associated with the

presence of curds in the stools, which requires the same treatment.

Something should be said regarding the changes required in milk modification during very hot weather. At such times both the proteids and fat must be reduced, but particularly the latter. An infant can no more digest a high percentage of fat during hot weather than a soldier in a tropical climate can. It is seldom wise in any case, even of perfectly healthy children, to have the fat in the summer months over 3 per cent., and during short periods of excessive heat it should be reduced to 2 per cent. The reduction required in the proteids is not quite to the same degree. If we wish to reduce both fat and proteids, it is not necessary to change the formula given the mother, but simply to instruct her to dilute the whole food by taking out, according to circumstances, one fourth or one half the milk from the bottle, and replacing it with water during the short period while excessive heat lasts. Where a greater reduction in the fat than in the proteids is required, the change should be made from the first to the second series of formulas or from the second to the third. By these changes a large amount of indigestion incident to hot weather can be avoided and many severe attacks prevented.

The scope of this paper does not include a consideration of abnormal cases or those of infants with very feeble digestion, or of those who suffer from chronic indigestion, to which in many cases there is added a condition of malnutrition. Each one of these cases must be studied and treated by itself, and an adequate discussion of the subject would require a volume.

14 WEST FIFTY-FIFTH STREET.

DYSPEPTIC ASTHMA.

By FRANK H. MURDOCH, M. D.,

PITTSBURG, PA.

HEMMETER (1) writes of dyspeptic asthma as follows: "A fear of smothering, with cyanosis, cool extremities, greatly hurried pulse and dyspnoea, occurring in the sequence of gastro-intestinal disturbances, represent a clinical picture, which we can designate as asthma dyspepticum."

In the chapter on chronic gastric catarrh, Einhorn (2) says: "After meals there is a sensation of fulness in the gastric region, and the patient feels oppressed. This feeling, if present in a higher degree, sometimes gives rise to symptoms of quite an alarming nature. Thus the patients complain of palpitation of the heart, and shortness of breath (asthma dyspepticum). The oppression experienced is relieved by belching."

Ewald (3), in speaking of pneumatosis or tympanites, says: "Here the stomach is filled with gas, and may become so distended that it causes, not alone the unpleasant sensation of marked tension, but even severe nervous symptoms, by pushing the diaphragm upward, and pressing against the heart. The patients are seized with typi-

cal attacks of asthma, the asthma dyspepticum of Henoch, in which there is only the annoying feeling of being compelled to take deep inspirations, after short periods of normal breathing. At the beginning this suffices; but later it develops into an incessant dyspnoea. Now there is also palpitation of the heart, pulsation of the peripheral vessels, fulness of the head, and even the feeling of impending death or complete unconsciousness. Relief can only be afforded by bringing up some of the gas, and then the attack rapidly subsides. In Allbutt's *System of Medicine* (4) the disease is thus described: "The asthmatic attacks (asthma dyspepticum) appear suddenly after meals, and are characterized by urgent dyspnoea, cyanosis, and a slow or irregular pulse. The symptoms rapidly subside after vomiting has taken place."

The authors quoted agree pretty closely in their description of the acute form of the disease, with its sudden onset and rapid subsidence of all the alarming symptoms so soon as the stomach is emptied of gas or other offending material. But there is another form of the disease, chronic dyspeptic asthma, which I have not heretofore seen described, and which is characterized by great shortness of breath on slight exertion, the condition being not paroxysmal, but continuous; it occurs in patients suffering from gastro-intestinal diseases, without any abnormal condition of the heart, lungs, or kidneys, sufficient to account for it, and yields readily to treatment directed against the existing dyspepsia.

Patients suffering from this form of the disease, do not experience shortness of breath to any great degree after eating. Vomiting has not occurred in the cases that I have seen, and the dyspnoea has, as a rule, not been relieved by belching. The shortness of breath is constantly brought on by some trifling exertion, as walking, going up stairs, stooping over to lace the shoes, or putting the clothing on or off. One man got quite out of breath in my office from simply taking off his coat, vest and shirt, for examination. As soon as he lay or sat down he was able to breathe quietly, only to experience shortness of breath again while dressing. One patient was obliged to sit down or lean against a building three or four times in going from his home to his place of business; and another had to rest in a similar manner seven or eight times while walking from the railroad station to my office, a distance of half a mile.

In some cases, slight exertion soon after meals caused greater shortness of breath than the same amount of exertion would cause at other times of the day. Some of the patients suffered from attacks of dyspnoea during the night. One patient, when an attack came on, would rush to an open window for air; another would grasp the mantel or head of the bed and struggle for breath; while yet another was relieved by rising and moving round the room. In all three, the attacks passed off in a few minutes without vomiting or raising gas, and without the administration of medicine.

As examples of chronic dyspeptic asthma the following cases may be of interest:

CASE I.—On November 1, 1896, Mr. J. K. P., aged sixty-three years, came to me complaining that for four years past he had suffered from shortness of breath on slight exertion to such an extent that he was obliged to rest, either by sitting down, or by leaning against a building three or four times while walking from his house to his store, a distance of about a third of a mile. He also complained of bloating and belching, and had lost eighteen pounds in weight. His appetite was good, his bowels regular, and he slept well. *Physical examination:* His lungs were clear; at the apex of the heart, as well as over the aortic area, a loud systolic murmur could be heard; the liver was normal; the stomach in normal position, but distended with gas. Examination of the stomach contents after Ewald's test meal showed that free hydrochloric acid and rennet were absent; rennet zymogen was present; total acidity, 8. Treatment consisted in a regulated diet and lavage to be used three times a week. I did not see this patient again for a year, when he reported that shortly after commencing treatment he began to improve, and in four or five months the shortness of breath ceased to trouble him, he regained what he had lost in weight, and now considered himself perfectly well.

CASE II.—September 29, 1898, Mr. J. P. D. complains of shortness of breath on slight exertion, as walking or leaning over to lace his shoes, or on any excitement, as going on the witness stand, the condition having lasted for ten years. Is short of breath without any exertion for about an hour after meals, feels best when the stomach is empty. In 1892 he had bronchial asthma. In 1893 he went to Colorado, and also took iodide of potassium, which cured his asthma; but the peculiar shortness of breath continued to grow steadily worse, so that now he has to rest seven or eight times while walking from the railroad station to my office, a distance of half a mile. Occasionally during the evening, while sitting reading, or after he has lain down, he is suddenly seized with an attack of urgent dyspnoea, which lasts only a very short time, and passes off as quickly as it came without anything being done for its relief. During the paroxysm he rises and grasps the mantel or head of the bed, and remains in that position till the end of the attack. These attacks only come on when he thinks of something that worries him. Appetite good, bowels constipated, he sleeps well and has lost fifteen pounds in weight. *Physical examination:* Lungs perfectly clear; simple hypertrophy of the left side of the heart; apex beat in nipple line and two inches below; stomach normal. Colon filled with gas. Examination of stomach contents after Ewald's test meal showed absence of both free hydrochloric acid and rennet. Rennet zymogen present. Total acidity, 4. His diet was regulated and intragastric faradization was used for some weeks. The patient improved quite rapidly and in about six months the shortness of breath ceased to trouble him. I saw him a few weeks ago and he told me he was quite well, and was only short of breath if he attempted to climb stairs or walk uphill too rapidly.

CASE III.—May 18, 1899, Mr. J. H., aged fifty-four years, has complained for nine years past of great shortness of breath on making any unusual exertion, as running or walking rapidly uphill. For six months he has been short of breath on slight exertion. For instance, he can stand long enough to wash his face and hands, but

has to sit down while drying them. He has to rest after putting on each individual article of clothing, and goes through the same routine while undressing. He cannot stoop over to lace his shoes at all, and consequently wears gaiters; walking on level ground or going up one flight of stairs puts him out of breath so that he has to stop and rest frequently. Eating seems to make no difference in his case, but drinking water increases the dyspnoea. Appetite good, bowels regular. While sleeping he either talks in a mumbling sort of way, or moans as if in agony, but does not have to sit up on account of shortness of breath. *Physical examination*: Coarse râles round the base of the right lung; left lobe of the liver somewhat enlarged; heart normal. *Examination of stomach contents*: Free hydrochloric acid, rennet, and rennet zymogen, absent. Total acidity, 8. Treatment, regulated diet and lavage. I have not seen this patient since the first examination, but his son has informed me that since October, 1899, he has had no shortness of breath and sleeps quietly.

CASE IV.—February 20, 1900, Mrs. G., aged thirty-five years. Four years ago, during pregnancy, she had an attack of bronchial asthma, but for two years after the birth of the child she was free from it and felt well. Then she began to complain of shortness of breath on slight exertion, which has gradually grown worse, so that at present, walking on a windy day, walking rapidly, or going up stairs, causes so much shortness of breath that she has to stop frequently to rest. She occasionally wakes up at night gasping for breath and rushes to a window for air. The attack passes off in a few minutes. The patient looks well, has not lost flesh; the abdomen is prominent, so much so as to suggest advanced pregnancy. Appetite good, bowels regular, sleeps well when not short of breath. *Physical examination*: Lungs perfectly clear, heart normal, stomach and intestines greatly distended with gas. *Examination of stomach contents*: Free hydrochloric acid, 32; acidity, 56; urine normal. *Treatment*: Regulated diet, bismuth subgallate, and heroine to be taken if short of breath at night. March 8th, very much better, bloating nearly gone; she can walk half a mile quite rapidly without getting out of breath. May 14th, the patient feels well.

CASE V.—August 2, 1900, Mr. D. H. P., aged fifty years. Twenty years ago he had an attack of shortness of breath, which lasted three or four days, being worse at night. Ever since, he has had similar attacks once or twice a year. Two years ago, following an attack of acute bronchitis, he had an attack of acute Bright's disease with convulsions and loss of consciousness. For three or four months past he has had constant shortness of breath on slight exertion, as walking or going up stairs. He also sleeps badly and frequently has to rise and move round on account of being short of breath. He is quite corpulent, being 5 feet 8½ inches in height and weighing 180 pounds. He is much troubled with bloating and belching, and is gloomy and depressed. Appetite fair, bowels constipated. *Physical examination*: Lungs perfectly clear; heart normal; liver normal. Taking off clothing for examination causes shortness of breath. Urine contains neither sugar nor albumin. *Examination of stomach contents*: Free hydrochloric acid, 48; acidity, 60. *Treatment*: Regulated diet, bismuth subgallate and sodium bicarbonate; heroine at bedtime. August 28th, is feeling somewhat better. For the past two weeks he has not had to get up at all at night, although he has only taken the heroine occasionally. I have not seen this patient since August, and therefore do not know whether he continued to improve or not.

From the report of these cases it will be seen that three of the patients were suffering from achylia gastrica, one from hyperchlorhydria, while in one, the gastric secretions were about normal, so that chronic dyspeptic asthma is not constantly associated with any one form of stomach trouble. None of the five, however, came complaining of dyspepsia; what they did come for, was to obtain relief, if possible, from the distressing shortness of breath from which they suffered. It will also be seen that while an acute attack of dyspeptic asthma, coming on as it does after a meal, is relieved, for the time at least, only by emptying the stomach, the dyspnoea attending the chronic form of the disease, being induced by exertion, however slight, is temporarily relieved only by rest. In Case II the sudden attacks coming on at night were always the result of mental worry, and so it is fair to suppose that the attacks of a similar character experienced by Cases IV and V were also due to a disturbed condition of the nervous system. In both the acute and chronic forms of the disease, permanent relief can only come from restoring the digestive organs to a healthy condition.

SOME REMARKS UPON TUBERCULOSIS IN BONE.

BY EDMUND OWEN, M. B., F. R. C. S.,

LONDON, ENGLAND,

SURGEON TO ST. MARY'S HOSPITAL AND CONSULTING SURGEON TO
THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET.

TUBERCULOSIS, like syphilis, is very apt to attack bone. But, whereas syphilis boldly attacks, as a rule, the firm, compact part of a bone—especially the shaft of a long bone—tuberculous inflammation generally makes for the delicate growing end of a diaphysis or the spongy tissue of a small bone.

Of all the small, spongy bones none are so often the seat of the disease as the bodies of the vertebræ. But I might become unduly wearisome if, following my own inclination, I were to enter upon the discussion of the pathology and treatment of spinal caries; so I will pass it by, and will make a few remarks upon tuberculous disease of the bones of the hand and foot, and upon what I will call the ultra-conservative treatment of tuberculous of bones and joints.

Of all the bones of the foot, I think that the astragalus is the one most often the seat of primary tuberculous, the disease most often following a sprain or twist, or some other injury. At first there are dull pains in the upper tarsal region, and, later, there is some tenderness on making deep pressure, but there is no discoloration of the skin, nor is there heat or œdema.

It might be impossible to make a precise diagnosis at this stage, but, later on, as the deposit increases, the ankle-joint becomes disturbed, effusion takes place into it and it is stiff. Then, as the inflammation extends forward, the joint between astragalus and scaphoid is implicated and local swelling and tenderness become marked. Could we at this time look into the interior of the bone, we should find that all the cancellous material had been replaced by granulations and that the articular lamellæ of compact tissue had also disappeared in places, as also the incrustation cartilage; that the neighboring synovial membrane was either represented by the same unhealthy granulations, or, if less damaged, appeared thick and cedematous. At this period there is considerable puffiness about the astragalus, and if a surgeon is seeing it for the first time he at once says to himself: "Is the ankle-joint affected or not?"

If he finds a bulging beneath the tendons at the front of the ankle, and also between the back of the joint and the tendon of Achilles, and if at the same time there is a fulness about the malleoli, there is then no doubt that the ankle-joint itself is diseased. Then, if the case is allowed to drift on, the granulation tissue will undermine and traverse the skin, fluid will escape, and permanent sinuses will form, in the depths of which the probe will discover soft, spongy, carious bone.

But possibly the sinuses have now been discharging many, many months.

What is to be done? "Scrape," says one surgeon. But if the scraping is thoroughly effected, it is found at last that a very small amount of respectably healthy tarsus has been left, and more sinuses than ever are left to discharge.

I have a full clinical record of a case of this sort, which has been under the care of a first-rate practical surgeon in the provinces for ten or a dozen years. The patient is now twenty-six years of age. He was sent to me first by the surgeon last May. There were many scars about the ankle and tarsus; the ankle-joint was synostosed in good position, but there was a tuberculous ulcer over the inner side of the astragalus, which, possibly, was connected with a little patch of diseased bone beneath. The old, extensive disease was, however, apparently at an end. "What shall I do?" said the surgeon. I advised his giving it a final scraping, which he did with excellent result, at any rate as regarded the ulcer and the sinus.

Last month I saw the young fellow again (for the second and last time). The ulcer was well, but he said that the foot ached if he ever tried to walk on it.

He told me that for over ten years the annoyance caused by this foot had clouded, even if it had not spoilt, his life; and that it had recently been the cause of his having to decline the proposal in a partnership business, which offered him all that he could have desired.

I asked him in a casual sort of way if his good surgeon had ever said anything about amputation. To this

he replied that, years ago, he (the patient) had suggested amputation, but the surgeon thought that the improvement already obtained had put amputation out of the question. I reminded the patient that by his patience and skill the surgeon had been enabled to save the foot, which was in itself a matter of sincere congratulation. To this he gave a somewhat doubtful assent.

In connection with this case I am going to make the assertion that, knowing what we do about tuberculosis, we sometimes err in carrying conservative treatment too far. As a rule, the objection to radical measures comes from the patient or his friends. But in this case the patient himself had proposed the adoption of a radical treatment.

The boy felt that his foot was given him to walk on, and for ten years it had not only been useless to him, but a constant source of annoyance. He was far worse off than a certain man who had a fig tree planted in his garden, as only for "three years" had he sought fruit thereon and found none. "Cut it down," said he, the business man and proprietor; "why cumbereth it the ground?" "Give it another chance," said the husbandman. "Cut the useless foot off," said our patient. "Let it alone this year also," said the surgeon, "till I shall dig about it and dung it," or, in other words, "till I shall scrape it out and stuff it with iodoform."

I am not going to preach a sermon on this delightful parable, but I will remind the reader that the conservative dresser of the vineyard did not ask for *unlimited* time; he was going hopefully to carry out his treatment only for *twelve months*.

I do not know what reminds me of it, whether it is the Scriptural reference, the mention of serious articular tuberculosis, or my remark about it being possible for us to carry conservative surgery too far, but, as I write, the case of a clergyman recurs to my mind.

When he first came to me he was a weedy, pale-faced undergraduate at Oxford, and he showed me a knee with the ovoid enlargement of advanced tuberculous disease. I advised him, as nineteen surgeons out of twenty would have done, that he should let me excise the joint without delay. He said he thought I should advise that, but that he had a friend at college whose knee had been excised, and that his rigid limb was always in the way at church and at theatre, in train and omnibus, and that he had quite made up his mind to have amputation done and so effectively and entirely to rid himself of his disease. So, with much reluctance, I amputated in the lower third of the thigh.

Some years afterward, when I saw him as a curate, I asked if he had regretted the amputation, to which he replied: "Never for one moment!" This autumn he has proudly walked with a smart artificial leg into matrimony and a rectory, and I fully expect that by next Midsummer Day he will have christened his first pair of twins.

I do not think that a man with a resected knee-joint, and, therefore, with a stiff leg, could ever evolve into a

bishop, and possibly he was thinking of this when he decided in favor of an amputation and an artificial leg. And, personally, I am of opinion that his decision was the correct one.

No one will, I trust, from these remarks, rashly conclude that I am an advocate for radical treatment in all cases of tuberculosis. On the contrary, I think that if I make a mistake it is in the cause of conservatism in surgery. I was a student under, and a house surgeon to, Samuel Lane, himself a pupil of Brodie, and I had ample opportunity under him of seeing that, even in the latter half of the nineteenth century, Nature still retained a mighty healing power. And these old-fashioned ideas still cling to me, I am glad to say.

Nevertheless, I have, I admit, performed Syme's amputation in a very large number of cases of tuberculous disease of the tarsus in hospital work—though only once in private practice—and I have not seen reason to regret it in any one instance. But with leather splints, with lateral splints of plaster of Paris, and with Thomas's knee-splint much can be done in the way of the successful and conservative treatment of chronic tuberculous disease of the foot.

64 GREAT CUMBERLAND PLACE, HYDE PARK, W.

A CASE OF GANGRENOUS INFLAMMATION OF MECKEL'S DIVERTICULUM SIMULATING APPENDICITIS.

By LIEUTENANT C. R. DARNALL,

ASSISTANT SURGEON U. S. ARMY, HOSPITAL SHIP "RELIEF."

It is stated in the text-books that in about two per cent. of all autopsies a Meckel's diverticulum is found. Usually, however, it is very small and frequently amounts to nothing more than a mere sacculum or pouching of the ileum. In a number of instances it has been found to be the source of intestinal obstruction. Richardson (Dennis's *Surgery*) states that in some instances a diagnosis of intestinal obstruction has been erroneously made in a general peritonitis from perforation of Meckel's diverticulum, and mentions Doran's case of perforation by a pea as an instance. The same author says that he has twice made a diagnosis of acute appendicitis when the symptoms were due to obstruction caused by Meckel's diverticulum. In one of these cases the diverticulum was found to be distended and gangrenous.

I am, for want of facilities, unable to review the latest literature on this subject.

The following case was admitted to the hospital ship *Relief* on June 11, 1900:

H. M., a corporal of Company B, Twenty-eighth Infantry, U. S. Volunteers, native of New York, aged twenty-two years; admitted at Taal, Luzon, P. I., June 11, 1900, at 9.30 A. M. Diagnosis on transfer slip: "Undetermined." History: Had been on an expedition into the country a few days previous to the arrival of the *Relief* on the afternoon of June 10th. He was feeling

well until about June 8th, when he had some pain in the abdomen, and a feeling of weakness and exhaustion. He arrived at Taal on the evening of June 9th, with pain in the abdomen and vomiting. He was admitted to the battalion hospital at Taal about 11 P. M., June 9th. He had tympanites, vomiting and pain and tenderness in the abdomen. A dose of magnesium sulphate was given, which he did not retain. Morphine was administered hypodermically to relieve pain. The bowels moved spontaneously at 3 A. M. on June 10th. This was the last natural faecal evacuation. The distention and vomiting increased. Enemata were given without effect. About 3 P. M. the patient suddenly passed into a state of collapse. The surgeon states that the tympanites was very great at this time; temperature subnormal; pulse thready; surface cold, etc.

The *Relief* arrived in the harbor at 4.30 P. M.; the surgeon came on board immediately and reported the condition of the man, and stated that he considered the case one of intestinal obstruction which demanded immediate operation. Dr. Menage, acting assistant surgeon, and myself were detailed to examine the case, and saw the patient about 7 P. M.

His condition was as follows: Skin cold, pale, and clammy; features pinched and drawn; eyes sunken. He was in a condition of semi-narcotism, presumably due to the opiates which had been administered. The pupils were somewhat contracted, the respirations hurried, the pulse small and thready, 116 a minute. He vomited a yellowish green fluid at frequent intervals. There was moderate tympanites. There was tenderness all over the abdomen, most marked in the umbilical region. Temperature 100° F. Some rigidity of the abdominal muscles, rather more marked on the right than on the left side.

As the surgeon said his condition had improved considerably within the last few hours, and as the facilities for an operation were very poor, it was decided to wait until morning. On June 11th, at 7 A. M., his condition was unimproved; temperature 100.6° F., pulse 120; no bowel movement, although he had received repeated enemata. Vomiting continued at frequent intervals. The vomited matter had, at this time, a distinctly faecal odor. He was transferred to the *Relief* at 9 A. M. After a careful examination, a diagnosis of appendicitis was made and an operation decided upon. He was operated on at midday, his temperature at this time being 100.5° F. The operation was performed by Captain DeShon, assistant surgeon, U. S. Army, assisted by Dr. Menage and myself. On opening the abdominal cavity in the right iliac region, the caecum and appendix were found to be absolutely normal in appearance. There was no more than the ordinary amount of distention in the colon, and that of the ileum was rather less than normal. There was no excess of fluid in the abdominal cavity and no evidence of peritonitis. The small intestine was rapidly traced upward and presented in every part a normal appearance. The wound in the abdominal wall was closed and the usual dressings applied. During the operation about two pints of normal saline solution were injected under the skin in the left mammary region. His temperature at 4 P. M. was 99° F.; general condition good. At 7 A. M., June 12th, the temperature was 101° F.; pulse 100; no vomiting; condition good; his mental condition was normal, and he took the first nourishment he had had for three days. At 7 P. M. the temperature was 100° F.; pulse 80, full and strong. At 7 A. M., on June 13th: Temperature 99° F.; pulse 80; no vomiting; con-

dition good. At 3 P. M. his condition became suddenly worse, all his former symptoms having returned. Pulse rapid and thready; skin cold, pale, and covered with perspiration; vomiting; features pinched. At 7 P. M. his temperature was 101.2° F.; pulse 120; tympanites and tenderness were marked all over the abdomen. All the symptoms of a general peritonitis were present at this time. At 7 A. M., on June 14th, the temperature was 100° F.; condition very bad. He gradually became worse, death occurring at 11 P. M. on June 14th.

Autopsy.—Abdomen very much distended. Condition of the wound in iliac region good. On opening the abdomen a condition of intense general peritonitis was found. The peritonitis was rather less marked in the vicinity of the operation wound than elsewhere. There was in the abdominal cavity a great excess of fluid which was seropurulent in character. The vessels of the peritonæum and mesentery were extremely engorged. The intestines were much distended with gas. The cæcum and appendix were normal, barring the recent condition of peritonitis. On further examination, a Meckel's diverticulum was found springing from the ileum about 3 feet 6 inches from the ileo-cæcal valve. It was six inches in length, its distal extremity about one half the diameter of the other, being firmly attached to the abdominal wall at the umbilicus. It arose from the ileum at a right angle, and at its attachment the diameter was about two thirds that of the intestine, readily admitting the finger. It gradually diminished in diameter toward its distal extremity. It was patulous throughout its whole extent. There was no torsion nor kinking, nor was there any obstruction of the gut demonstrable at the autopsy. At its attachment to the ileum, and for about two inches from that point, the diverticulum appeared to be normal, but at the latter point began a large gangrenous patch which extended along the diverticulum for about one inch and a half, and which at its widest part measured three quarters of an inch. Near the centre was a perforation about two millimetres in diameter. The diverticulum contained about an ounce of offensively smelling fluid.

Remarks.

In considering this case a very interesting question arises, viz: Was the affection of the diverticulum primary or secondary? Was it, like acute gangrenous appendicitis, the cause of the apparent obstruction when the patient first came under observation, or did the diverticulum, acting as a band or cord, cause the obstruction, itself subsequently becoming gangrenous from pressure?

The early and constant, though not great, elevation of temperature, the evidence of severe infection, the incomplete obstruction of the bowels as shown by the small amount of tympanites, are compatible with the former view, while the fact that such marked improvement followed manipulation of the intestine at the time of the operation, might be taken as evidence that there was, at first, an obstruction caused by the diverticulum, and that the diverticulum became gangrenous in consequence of the pressure exerted upon it. When, during the operation, the obstruction was relieved, the patient's condition improved. The pressure on the diverticulum had so damaged it, however, that gangrene, progressing to perforation, ensued, and the return of the symptoms, followed quickly by death, was due to the general peritonitis following the perforation. This may be considered as

being more probable from the fact that the diverticulum, having no mesentery of its own, was unable to resist pressure on it for any considerable length of time without serious interference with its nutrition, as the greater part of its blood supply was necessarily received through its intestinal attachment.

Considering the question pro and con., however, I am inclined to favor the former view as expressed above, viz.: That the diverticulum was primarily affected and that the morbid process in it was analogous to that occurring in acute gangrenous appendicitis. This opinion is based on the reasons expressed above and also on the great similarity of the symptoms in this case to the symptomatology of that disease. The temporary abatement in the severity of the symptoms can be referred, I think to the repeated subcutaneous injections of normal saline solution the patient received during, and subsequently to, the operation; his condition remaining fairly good until perforation took place.

The specimen of the diverticulum and contiguous portion of the ileum in this case has been sent to the laboratory of the First Reserve Hospital, Manila, P. I., for shipment to the Army Medical Museum, Washington, D. C.

Therapeutical Notes.

Injections of Cod-liver Oil Emulsion in Tuberculosis.

—Zenner (*Therapeutische Monatshefte*, No. 6, 1900) reports a case of tuberculosis in which he has obtained good results from the use of rectal injections of an emulsion of cod-liver oil. The following emulsion was injected every morning in quantities varying between 60.0 and 100.0 grammes:

℞ Purified pancreatin. 5.0 grammes;
Inspissated ox-gall. 0.5 “
Sodium chloride. 1.5 “

M.

To be dissolved in fifty grammes of water and digested for two hours with 250 grammes of pale cod-liver oil; then add twelve drops of ethereal oil of eucalyptus.

The injections were well borne, and were retained in the intestine. Investigation of the fæces showed that only 24.6 grammes out of the 100 grammes introduced were again discharged before the next injection. It is not necessary to precede the nutrient enema with a cleansing injection.

For Lupus.—Beilage (*Dermatologisches Centralblatt*, June, 1900; *British Medical Journal*, December 22, 1900) recommends this formula as Unna's:

℞ Salicylic acid, }
Solution of chloride of } of each. . . . 2 parts;
antimony, }
Creosote, }
Extract of cannabis indica, } of each. . . . 4 “
Lanolin. 8 “

M.

The antimony is said to kill the bacilli, the creosote and cannabis indica to allay pain, and the salicylic acid to aid penetration. When the disease is deep the solution of chloride of antimony is applied on wooden matches, the ends of which are cut off and left *in situ* for forty-eight hours.

NEW YORK, SATURDAY, JANUARY 12, 1901.

NEW YORK'S OPPORTUNITY IN PSYCHIATRY.

THE unfortunate incident of a man's having apparently been pounded or choked to death in the lunatics' quarters in Bellevue Hospital is not a proper subject for us to discuss, for it is before the courts. It may, however, and we sincerely trust it will, pave the way to an institution which New York ought long ago to have had, a hospital for acute cases of mental disturbance. In every other branch of medicine than psychiatry New York has unexcelled facilities for teaching, and the popular mind at the present time seems to have been prepared by the sad occurrence in question to demand the establishment of an institution of the kind desired. The general practitioner of medicine is rarely called upon to struggle with the problems of chronic insanity, but the varying phases of acute mental aberration confront him frequently; hence it is with those forms of disordered function that he needs to be made familiar.

The island institutions, now that they have come under State control, are fairly creditable retreats for indigent persons who are chronically insane, but they are not favorably situated for ready access on the part of our medical students, and, taking into account the average medical man's lack of interest in chronic insanity, we may say that they are hardly worth the trouble of an occasional visit, especially as the clinical instruction provided within their walls is scanty and wide of the general practitioner's scope. Let such a hospital for cases of acute mental disturbance be established in the borough of Manhattan, under the care of the State board of lunacy and in convenient proximity to the State pathological institute, and clinical teaching in psychiatry as it appeals to the family physician will at once take its proper place in the school curriculum. It is often the direst necessity that brings forth the best result, and we trust that New York's present apparent incapacity to

deal scientifically, and consequently humanely, with persons suddenly deprived of their mental balance may prove the stimulus to such provision for the acutely insane as may be a boon to them and a precious agency in the education of coming generations of physicians. Now, when the case of supposed homicide is fresh in the public mind, is the time to strike for it.

THE BACTERIAL SELF-PURIFICATION OF STREAMS.

(*Second Article.*)

IN our last issue we gave a brief summary of Dr. Jordan's tests. No doubt the reader has been struck with the sudden and decided increase of bacteria at Wesley City, following upon a gradual and steady diminution from Chicago. This is attributable to the large amount of organic refuse that finds its way into the Illinois River with the sewage of Peoria reinforced by the waste of manufactories, distillery slop, discharges from glucose factories, and the sweepings of extensive stock yards. The Wesley City specimens of water were taken from a point about four miles below this "outpour of pollution," which is said to vary greatly at different seasons of the year and at different hours of the day, thus accounting for the great irregularities and fluctuations in the number of bacteria observed at that point. Beyond Wesley City the gradual process of self-purification goes on as before. Taking the purifying process, then, as practically continuous, we at once find ourselves interested in what Dr. Jordan has to say of the elements concerned in it. Before proceeding to present this, however, we must remark that he quite frankly points out that the observations are open to criticism on the score that the specimens of water examined were transported and for the reason that they were not taken simultaneously from the different points. It seems that the bacteria multiply when the specimens are not packed in ice, and that in ice-packed specimens they decrease in number at first, but subsequently multiply to a number exceeding in some instances the original proportion. Allowance being made for these sources of error, which in some measure probably correct each other, it is not to be doubted that the general drift of the observations and of the deductions drawn from them may be taken as correct.

Among the supposed causes of the gradual disappearance of bacteria, Dr. Jordan first considers mechanical agitation and aeration. In so sluggish a stream as the Illinois, he says, there is not sufficient agitation to prove at all injurious to bacterial life; indeed, Meltzer's experiments point to the conclusion that moderate agitation is

not detrimental to bacteria. Aeration of the water to the extent to which it takes place in a river of slow flow may also be dismissed as having little effect in promoting the destruction of micro-organisms. The immediate effect of dilution with purer water from underground sources or from tributaries must, however, be in the direction of diminishing the proportion of bacteria in a given quantity of water, and Dr. Jordan finds it difficult to understand, as we do also, why this effect is sometimes referred to as not being a "true" purification. If, he says, a sample of water contains a hundred typhoid-fever bacilli to the quart, and is diluted to twenty times its bulk with pure water, each quart will contain only five germs, and, "apart from any influence the dilution may have upon the life of the germs, a purification of the water will have occurred to just the same extent as if ninety-five per cent. of the typhoid bacteria had perished, and the danger from drinking a small quantity of such a water would be diminished in exactly the same proportion."

As regards the action of sunlight, ordinarily accounted a potent element in aerial purification, the author is not prepared to make any very definite statement, but remarks that such incidental evidences as were gathered do not warrant the attachment of great importance to it. The main bulk of a body of water, if even moderately high turbidity prevails, must, he thinks, be virtually unaffected by the sun's rays. Still, he does not affirm that they are always and entirely without effect upon the bacteria in river water, "although they certainly play an insignificant part in the case of turbid waters." The influence of the plankton, he remarks, is perhaps yet more problematical than that of sunlight, either by devouring the bacteria themselves or by consuming their means of sustenance. In the first place, he says, the albuminous substances that serve as food for bacteria cannot be so advantageously attacked by the plankton as by the bacteria; in the second place, there is ample laboratory evidence that a bacterial decrease always follows close upon a bacterial multiplication in sewage or polluted waters containing no plankton. In sedimentation Dr. Jordan finds a more potent element. When there is semi-stagnation of the water, he says, "the settling out of food substances, the entanglement of bacteria in slowly subsiding particles, and possibly the slow sinking of the bacteria themselves, all have the fullest play and must all work to diminish the number of suspended bacteria." "There can be no doubt," he adds, "that the various influences summed up by the term sedi-

mentation are sufficiently powerful to obviate the necessity for summoning another cause." Nevertheless, he thinks that due weight is not generally attributed to diminution of the substances, minute floating albuminous masses, upon which the bacteria subsist, and there is no need to assume that their diminution is wholly or even in large part due to the process of sedimentation. He makes this important statement: "I have been struck by nothing in the course of the investigation so much as by the absence of extensive deposits of the foul, black mud popularly supposed to accumulate on the bottom of sewage-polluted rivers. The bed of the Illinois between Morris and Ottawa is singularly free from any deep deposit of organic matter, although the current is very sluggish and sewage in increasing quantities has been poured into the river for thirty-five years. The solid organic matter in the sewage, therefore, is destroyed either while still in suspension or shortly after deposit. The natural effect of this shrinking of the food supply is to cause a diminution of the bacterial population dependent upon it."

The purity of drinking-water, as every physician knows, is of preeminent importance in the preservation of health, and everything that tends to promote it must claim earnest consideration on the part of the sanitarian. We must look upon Dr. Jordan's article, therefore, as of exceptional value. It may well be studied in its entirety as it appeared in the December number of the *Journal of Experimental Medicine*.

GRAINS, OUNCES, ETC., AND THE METRIC SYSTEM.

WE believe that a large proportion of American physicians would protest stubbornly against the obligatory use of the metric system of weights and measures, and evidently the last word on the subject has not yet been said in Great Britain. At a recent meeting of the Liverpool Medical Institution (*Lancet*, December 15th) Brigade Surgeon Lieutenant-colonel E. Nicholson read a paper on Medical Weights and Measures. He traced the evolution of the imperial weight from the Egyptian royal cubit through the Alexandrian talent and the Roman *libra*, and remarked that the ounce of the *British Pharmacopœia* differed from the Roman weight by only half a grain. He gave an account of the metric system and alluded to its fallacies. It was being vigorously pushed, he said, by advocates whose representation of the alleged irrationality and difficulty of the British system was due to ignorance of it. Anybody, he said, could decimalize the weights and measures for calculation or industrial

purposes, and he warned the medical profession against being lured into consent to the metric system by the plausible use of the word "scientific." He declared that even in France, after more than a century of official pressure and police action, the metric system was really disliked by the people, who merely submitted to it without accepting it, and evaded it whenever they could. If it was made compulsory in Great Britain, he went on to say, it would be really a revolutionary system, uprooting a great deal more than the weights and measures.

Dr. Karl Grossmann differed radically with Colonel Nicholson, looking upon the paper as an apology for the survival of the British system rather than an argument for its perpetuation. Whatever the ancient Egyptians had achieved, he said, their mode of measuring and weighing did not suit the present time, with its altered conditions of communication, so well as the decimal system. The relationship between the metre, the gramme, and the litre was simple and easily intelligible, and he maintained that the adoption of the metric system would do away with the useless incubus of the weights and measures in the old multiplication table and to that extent relieve the already overburdened brains of school children. The present English system did not show the survival of the fittest, but the persistence of the unfittest, and its proper place was with the cubit, in the museum among the relics of the past.

Neither disputant's contention seems to us to express much more than a personal conviction, and we do not believe that either system of weights and measures is essentially superior to the other; it is all a question of convenience. The school children of the present day, at least in the United States, are taught the metric system; to them it is familiar, and their difficulty is to reckon in grains, ounces, etc. To men and women of middle age, however, provided they have been brought up here and are not chemists or mathematicians, the metric system is a stumbling-block and must in most instances so remain. No doubt the metric system will be in universal use before many years have passed, but to the day of his death the physician who is in his prime now will shrink from the burdensome perplexity, to say nothing of the danger, of writing his prescriptions in grammes, decigrammes, centigrammes, and milligrammes; he will be apt, too, to take a humorous view of the practice of mingling the names of those weights with the word "drops" in a prescription. Hence, we think, the exclusive use of the terms of the metric system should not at present be adopted in medical writings.

THE PREVALENCE OF SMALL-POX.

WHILE cases have of late been reported from widely distant points, we still think there is practically no danger of a serious epidemic, provided, of course, the energetic course pursued by the New York city board of health is at all closely approximated in other municipalities. According to the returns to the surgeon-general of the Marine-Hospital Service for the week ending January 4th, no alarming number of cases occurred anywhere. Some of the newspapers have done their best to frighten the community, but of what consequence are eleven cases in New York compared with the 152 reported in Paris for the first week in December? Fortunately, our people appreciate the value of vaccination, and no antivaccination zealot can hoodwink any considerable portion of them.

THE MEDICAL CORPS OF THE ARMY.

ETERNAL vigilance is required to prevent Congress from impairing the efficiency of the medical corps of the army. The tendency constantly is to keep the number of medical officers below a safe minimum, and now the corps is threatened with degradation. We publish in this issue a circular to the members of the American Medical Association by its president, Dr. Reed, which sets forth this fact clearly. Though dated December 29th, Dr. Reed's circular did not reach us till this week; consequently there is no time to correct an apparent error of statement in the fourth paragraph, referring to a decrease in the grade of lieutenant-colonel "from 5.2 to 5.7 per cent." We presume this is a copyist's error, and it does not affect the general drift of Dr. Reed's statement or impair the force of his appeal. When the inducements to enter the medical corps are lowered, the efficiency of the corps is crippled and consequently the capability of the army as a whole is weakened. Dr. Reed urges every member of the medical profession to send at once to his senator and representative an emphatic protest against the proposed provisions. No time should be lost in this matter. His advice should be followed without the slightest hesitation.

THE DANGERS OF SOME UNCOOKED VEGETABLE FOODS.

IN our issue for February 10, 1900, we referred to the danger that tetanus and possibly other pathogenic bacteria might not infrequently be conveyed through the agency of celery, lettuce, radishes, strawberries, and other vegetable products that are commonly eaten uncooked. Yet other dangers arising from vegetable food products seem likely to be unmasked by the investigations of the laboratory commissioners recently undertaken in England as an outcome of the Manchester beer poisoning epidemic. It appears, according to the *Lancet* for December 22d, to have been established that plants actually take up arsenic in a soluble condition from the soil, and that such arsenic may easily accumulate in the soil in

dangerous quantities from the use of manures made by heating bone ash with commercial oil of vitriol. Cabbages and turnips gathered from fields manured with superphosphate of calcium are said to have given unmistakable evidence of the presence of arsenic. The repeated dressing of the fields with this fertilizer may cause the accumulation of the poison in the earth and its absorption in increasingly dangerous quantities by vegetables subsequently used in food. This is a condition undoubtedly deserving of serious consideration and investigation, and we trust that such investigation by competent authorities in this country will be forthcoming.

DYSTOCIA CAUSED BY RIGOR MORTIS OF THE FŒTUS.

DR. J. H. EVANS, in the *Australasian Medical Gazette* for November 20th, records two cases in which labor set in as a consequence of the death of the fœtus due to separation of the placenta. Both women were in the last month of pregnancy. Ordinary measures failing, the child was extracted in each case with the forceps, and was found to be in a state of extreme rigor mortis. While the possibility of rigor mortis as a possible cause of dystocia is not unknown, it is perhaps not sufficiently widely known. But few cases are on record, and very many textbooks do not refer to it. It is probable that rigor mortis may occur in the dead fœtus at any time after its muscles have become contractile, and will probably last longer and be more likely to prove an obstacle to parturition the nearer the gestation is to term. In both of Dr. Evans's cases the accident seems to have resulted from severe exertion, in one case thirty hours, in the other three, before labor set in.

FRAGMENTS OF GLASS FROM MILK BOTTLES.

THE bottles now in use for the delivery of milk are most ingeniously devised as regards convenience and cleanliness. Sometimes, however, they appear to be roughly handled, so that small particles of glass are chipped off from the mouth of the bottle. Falling into the milk, these minute fragments probably escape detection as a rule, but sometimes they are found by those who are careful to search for them. Doubtless their ingestion by infants occasionally accounts for a stain of blood in the stools. When once a bottle has been injured in this way, be it in never so slight a degree, its further injury is likely to be speedy. Purveyors of bottled milk should therefore be warned that every bottle with a chipped mouth should be discarded.

A NEW SPECULUM METAL.

A HIGHLY reflecting metal unaffected by air and water is, of course, a very suitable material for specula. Such a metal, according to the *British Journal of Photography*, cited in the January number of the *American Journal of Pharmacy*, is magnalium, described as a silver-white alloy of aluminum and magnesium. As it is attacked by alkalis, however, it should not be brought into contact with soap.

News Items.

Society Meetings for the Coming Week:

MONDAY, *January 14th*: New York Academy of Medicine (Section in General Surgery); New York Academy of Sciences (Section in Chemistry and Technology); New York Medico-historical Society (private); New York Ophthalmological Society (private); Lenox Medical and Surgical Society, New York (private); Harlem Medical Association of the City of New York; Gynæcological Society of Boston; Burlington, Vermont, Medical and Surgical Club; Norwalk, Connecticut, Medical Society (private).

TUESDAY, *January 15th*: New York Academy of Medicine (Section in General Medicine); Buffalo Academy of Medicine (Section in Pathology); Ogdensburg, New York, Medical Association; Syracuse, New York, Academy of Medicine; Medical Societies of the Counties of Kings (annual) and Otsego (semi-annual—Coopers-town), New York; Connecticut River Valley Medical Association (Bellows Falls, Vermont); Baltimore Academy of Medicine.

WEDNESDAY, *January 16th*: Medico-legal Society, New York; Northwestern Medical and Surgical Society of New York (private); New Jersey Academy of Medicine (Newark); Philadelphia County Medical Society.

THURSDAY, *January 17th*: New York Academy of Medicine; Brooklyn Surgical Society; New Bedford, Massachusetts, Society for Medical Improvement; Medical Society of City Hospital Alumni, St. Louis; Atlanta Society of Medicine.

FRIDAY, *January 18th*: New York Academy of Medicine (Section in Orthopædic Surgery); Clinical Society of the New York Post-graduate Medical School and Hospital; Baltimore Clinical Society; Chicago Gynæcological Society.

Army Intelligence:

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from December 22, 1900, to January 5, 1901:

ADAIR, GEORGE W., Major and Surgeon, United States Army, is detailed as a member of the retiring board appointed to meet in St. Paul, *vice* Lieutenant-Colonel Calvin De Witt, Deputy Surgeon-General, United States Army.

CLOUD, MARSHALL M., First Lieutenant and Assistant Surgeon, United States Army. The sick leave granted him is extended six months.

DRIVER, GERRY S., Acting Assistant Surgeon, United States Army, will proceed to Chicago for temporary duty as examiner of recruits.

GEORGE, WILLIAM R. S., Acting Assistant Surgeon, is assigned to duty at the post of San Juan, Puerto Rico, and will proceed there on the first transport sailing from New York.

JACKSON, THOMAS W., Acting Assistant Surgeon, United States Army, is ordered to San Francisco for duty with troops *en route* to the Philippine Islands.

PRESNELL, JAMES F., Acting Assistant Surgeon, United States Army, is assigned to duty on the transport *Thomas en route* to the Philippine Islands.

RICHARD, CHARLES, Major and Surgeon, United States Army, is detailed as an additional member of the general court-martial convened at Fort Leavenworth, Kansas.

RICHARDS, WILLIAM E., First Lieutenant and Assistant Surgeon. The leave of absence granted him is extended one month on account of sickness.

WARREN, HOBART E., Acting Assistant Surgeon, will report to Captain Richard H. Wilson, Eighth Infantry, for duty.

Naval Intelligence:

Official List of Changes in the Medical Corps of the United States Navy for the two weeks ended January 5, 1901:

BARBER, G. H., Surgeon. Commissioned surgeon from June 7, 1900.

BRADLEY, G. P., Medical Director. Commissioned medical director from May 31, 1900.

BRIINTER, J. M., Assistant Surgeon. Ordered to the *Independence*, January 13, 1901.

BURR, C. R., Assistant Surgeon. Order of December 19th revoked, and he is ordered to resume duties on the *Monongahela*.

CRANDALL, R. P., Surgeon. Detached from the *Constellation*, and ordered to temporary duty in connection with recruiting in Milwaukee, and then home to await orders.

FITZSIMMONS, P., Medical Director. Commissioned medical director from November 19, 1900.

LEDBETTER, R. E., Assistant Surgeon. Detached from the *Monongahela* and ordered to the *Constellation*.

MCCLURG, W. A., Surgeon. Detached from the *Indiana*, and ordered to the Naval Training Station, Newport, Rhode Island, to relieve Surgeon R. P. Crandall.

RODMAN, S. S., Assistant Surgeon. Appointed assistant surgeon from December 14, 1900.

Marine-Hospital Service Health Reports:

The following cases of small-pox, yellow fever, cholera and plague, were reported to the surgeon-general during the week ending January 4, 1900:

Small-pox—United States.

Washington, D. C.	Dec. 15-22	1 case.	
Jacksonville, Florida	Dec. 15-22	1 case.	
Cairo, Illinois	Dec. 15-22	3 cases.	
Chicago, Illinois	Dec. 22-29	2 cases.	
Wichita, Kansas	Dec. 22-29	2 cases.	1 death.
Decatur, Nebraska	April 1-Dec. 14	416 cases.	4 deaths
Manchester, New Hampshire	Dec. 22-29	14 cases.	
New York, New York	Dec. 22-29	11 cases.	2 deaths
Ashtabula, Ohio	Dec. 22-29	5 cases.	
Cleveland, Ohio	Dec. 22-29	20 cases.	
Central Falls, Rhode Island	Dec. 26	1 case.	
Memphis, Tennessee	Dec. 22-29	2 cases.	
Nashville, Tennessee	Dec. 22-29	1 case.	
Galveston, Texas	Dec. 17	6 cases.	
Houston, Texas	Dec. 22-29	25 cases.	1 death.
Salt Lake City, Utah	Dec. 22-29	32 cases.	
Wheeling, West Virginia	Dec. 15-22	3 cases.	
Green Bay, Wisconsin	Dec. 23-30	1 case.	

Small-pox—Foreign.

Buenos Ayres, Argentina	Oct. 1-30	22 cases.	14 deaths
Prague, Austria	Dec. 1-8	26 cases.	
Alexandria, Egypt	Nov. 26-Dec. 10	4 cases.	4 deaths
London, England	Dec. 1-15	2 cases.	
Paris, France	Nov. 24-Dec. 1	103 cases.	17 deaths
Paris, France	Dec. 1-8	152 cases.	14 deaths
Athens, Greece	Dec. 1-8	1 case.	
Bombay, India	Nov. 21-27		1 death.
Calcutta, India	Nov. 17-24		8 deaths
Madras, India	Nov. 17-23		1 death.
Licata, Italy	Dec. 8-15		1 death.
Vera Cruz, Mexico	Dec. 15-22		1 death.
Moscow, Russia	Nov. 24-Dec. 1	3 cases.	1 death.
Odessa, Russia	Dec. 1-8	23 cases.	7 deaths
St. Petersburg, Russia	Dec. 1-8	5 cases.	3 deaths
Warsaw, Russia	Dec. 1-8		15 deaths
Glasgow, Scotland	Dec. 15-21	67 cases.	3 deaths

Yellow Fever.

Havana, Cuba	Dec. 8-22	6 deaths
Vera Cruz, Mexico	Dec. 15-22	1 death.

Cholera.

Bombay, India	Nov. 21-27	2 deaths
Calcutta, India	Nov. 17-24	35 deaths
Madras, India	Nov. 17-23	1 death.

Plague.

Bombay, India	Nov. 21-27	58 deaths
Calcutta, India	Nov. 18-24	4 deaths
Osaka, Japan	Nov. 30-Dec. 4	4 cases.
Tamatave, Madagascar	Oct. 29-Nov. 18	1 case.

Marine-Hospital Service:

Official List of the Changes of Stations and Duties of Commissioned and Non-commissioned Officers of the United States Marine-Hospital Service for the Seven Days ending January 3, 1901:

AMESSE, J. W., Assistant Surgeon. On being relieved by Assistant Surgeon L. P. H. Bahrenburg, directed to proceed to Manila, Philippine Islands, and report to the chief quarantine officer for duty.

BAHRENBURG, L. P. H., Assistant Surgeon. Bureau order of December 27, 1900, directing Assistant Surgeon Bahrenburg to proceed to Manila, revoked; and directed to proceed to Honolulu, Hawaiian Islands, reporting to the chief quarantine officer for duty.

BREADY, J. E., Acting Assistant Surgeon. Granted leave of absence for four days from January 2d.

BROWN, B. W., Passed Assistant Surgeon. Relieved from duty at Cape Charles Quarantine and directed to proceed to Baltimore and assume command of the service, relieving Surgeon George Purviance.

KOLB, W. W., Hospital Steward. Granted leave of absence for thirty days from January 29th.

LLOYD, B. J., Assistant Surgeon. Granted leave of absence for eighteen days from December 11, 1900.

OLSEN, E. T., Hospital Steward. Granted leave of absence for five days.

PURVIANCE, GEORGE, Surgeon. Relieved from duty at Baltimore and directed to proceed to Washington, reporting at the Bureau for duty.

STIMPSON, W. G., Passed Assistant Surgeon. To proceed to Denver for special temporary duty.

WERTENBAKER, C. P., Passed Assistant Surgeon. To proceed to Shreveport, Louisiana, for special temporary duty.

WILLE, C. W., Assistant Surgeon. To assume temporary command of Cape Charles Quarantine, relieving Passed Assistant Surgeon B. W. Brown.

Casualty.

Acting Assistant Surgeon A. R. Booth died at Shreveport, Louisiana, December 27, 1900.

To Succeed Dr. Henry Noyes.—Dr. John E. Weeks, University of Michigan, '81, has been appointed to the professorship of ophthalmology in the New York University and Bellevue Hospital Medical College, made vacant by the death of Dr. Henry D. Noyes.

The Brooklyn Society for Neurology.—At the annual meeting of the Brooklyn Society for Neurology, held on December 27th, Dr. W. H. Haynes was elected president and Dr. B. Onif secretary for the ensuing year.

The New York Odontological Society.—The thirty-fourth anniversary of the New York Odontological Society will take place at the Academy of Medicine Tuesday, January 15th.

University of Tennessee.—Dr. W. D. Haggard, Jr., of Nashville, has been elected to fill the chair of gynecology and diseases of children, *vice* Dr. W. D. Haggard, Sr., resigned, who will become professor emeritus.

Old Officers of the Grady Hospital Reelected.—All the old officers and the staff of visiting physicians were reelected by the trustees of the Grady Hospital, Atlanta, Ga., at their annual meeting.

Epidemic of Grippe.—The grippe is reported to be prevalent at Milwaukee, and there are said to be between 300 and 400 cases of the disease in that city.

The Sing Sing Outbreak of Typhoid is stated to have been traced to a break in the prison water-supply pipe that runs through and around old-fashioned buildings having outside closets.

Chinese Practising Illegally.—Three Chinese doctors have been arrested in Kansas City, Mo., charged with practising medicine illegally.

The Eighth Pirogoff Congress will be opened in Moscow in December, 1901. Professor Bobroff has been appointed president of the committee on organization. There will be six sections: Biology, pathology, medicine, therapeutics, legal medicine, and hygiene.

Small-pox.—There appears to be no abatement to the epidemic which has struck the country, as reports come in from all points. Fortunately the disease appears to be of a mild type. In New York City but a few cases a day are reported. Other places at which the disease has broken out lately are Crawford and Cherokee counties in Kansas, Minnesota, and Kansas City, Mo. The Brook-

lyn Anti-Compulsory Vaccination League met recently in Brooklyn borough, and after changing its name to the New York City Anti-Vaccination League, Dr. Montague R. Levenson, the president, asserted that he had treated about thirty cases of small-pox without giving notice to the Board of Health, and that all his patients had recovered without a scar. For this bold admission the doctor may yet have to answer to the board, which has the case under advisement.

Gold Medals Presented to Physicians.—Dr. Francis Le Moynes, Dr. W. H. Daly and Dr. Emmerling, Sr., who now constitute the consulting staff of the West Penn Hospital at Pittsburg, Pa., were recently presented with gold medals for their services.

New York Produce Exchange Hospital Donation.—Contributions of members of the New York Produce Exchange for the benefit of the hospitals during the December collection of 1900 amounted to \$1,966.

Small-pox in St. Petersburg.—The epidemic has been successfully stamped out. The disease was fought by a special corps of physicians and students under the direction of Dr. V. O. Hubert. Over 300,000 persons were vaccinated during two months. The total expense for the campaign against small-pox was 34,000 roubles. In July the number of small-pox cases was 276, and in October only 35.

The York County Medical Society.—The York County (Pa.) Medical Society held its annual business meeting and banquet recently. Dr. W. S. Thaver, of Baltimore, gave a polyclinic lecture on lessons to be drawn from recent investigations in malarial fever. The new officers of the society are: President, Dr. Roland Jessop, York; vice-presidents, Dr. N. C. Wallace, Dover; Dr. J. C. Murphy, York Haven; secretary, Dr. R. A. Harding, York; treasurer, Dr. J. F. Klinedinst, York; censors, Dr. Laura J. Dice, Dr. A. A. Long, Dr. W. F. Bacon, York; examiners, Dr. W. C. Stick, Glenville; Dr. H. E. Leckrone and Dr. G. Holtsapple, of York.

The Pan-American Medical Congress.—The Third Pan-American Medical Congress will be held at Havana from February 4th to 8th, inclusive. Delegates can go either by the land routes, which are all via Florida, or by the water route from New York City. Full particulars, concerning these routes, excepting that of the Ward Line steamers from New York, will be found in the *Journal of the American Medical Association* for November 6th. Those coming from south of Washington and west of Pittsburg will probably select the Florida route, while those from the northeast will find the Ward Line more convenient. The steamer *Seguranca* of the Ward Line leaves New York on January 30th, arriving in Cuba on February 3d, the day before the beginning of the congress. The new Ward Line steamer *Morro Castle*, holding 135 cabin passengers, leaves Havana on February 9th, reaching New York February 11th. The round trip costs \$70.00. Any one going by this route will be absent from New York twelve days. All information regarding transportation may be had from Dr. H. L. E. Johnson, 1402 L Street, N. W., Washington, D. C.

New Officers of the Western Surgical and Gynecological Association.—Dr. A. F. Jonas, of Omaha, Neb., was recently elected president of the Western Surgical and Gynecological Association. The other officers are:

First vice-president, Dr. A. W. Abbott, of Minneapolis; second vice-president, Dr. C. E. Ruth, of Keokuk, Ia.; secretary-treasurer, Dr. George H. Simmons, of Chicago. Executive council, Dr. H. C. Crowell, of Kansas City; Dr. John P. Lord, of Omaha; Dr. James E. Moore, of Minneapolis; and Dr. M. S. Harris, of Chicago. Chicago was selected as the place for holding the next annual meeting.

Berrien County Medical Society.—At the annual meeting of the Berrien County Medical Society at Benton Harbor, Mich., recently, the following officers were elected: President, Dr. H. V. Tutton, Benton Harbor; vice-president, Dr. Robert Henderson, Buchanan; secretary, Dr. Wakeman Ryno, Benton Harbor; treasurer, Dr. Hattie Schwendener, St. Joseph.

German Medical Society of Cleveland.—The second annual meeting of the German Medical Society was held recently at Cleveland, Ohio, and the following officers were elected: Dr. C. Schmitz, president; Dr. T. Belkowsky, vice-president; Dr. M. Kahn, secretary; Dr. L. Reich, corresponding secretary; Dr. I. T. Propper, treasurer.

The New York State Medical Society.—The ninety-fifth annual convention of the New York State Medical Society will be held in Albany January 29th, 30th and 31st. Many papers will be read and a demonstration clinic will be held at the Albany Hospital under the direction of Dr. Albert Van der Veer. Dr. Willis G. MacDonald and Dr. Samuel B. Ward, with a discussion upon a paper to be presented by Dr. Charles A. L. Reed, of Cincinnati, president of the American Medical Association. Dr. J. Collins Warren, of Boston, will lead a discussion upon the Surgery of the Spleen.

St. Louis Medical Society Meeting.—The following papers were read and discussed at the recent meeting of the St. Louis Medical Society: Excision of the Intact Gasserian Ganglion, with a Report of Two Cases of Trifacial Neuralgia Successfully Treated by this Means, by Dr. Willard Bartlett, and A Report of the Microscopic Findings in the Above Cases, with a Literature Résumé on the Neuro-pathology of the Subject, by Dr. Sidney I. Schwab.

Officers of the College of Physicians at Philadelphia.—At a recent meeting of the College of Physicians of Philadelphia the following were elected officers: Dr. W. W. Keen, president; Dr. H. C. Wood, vice-president; Dr. William F. Norris, Dr. R. A. Cleemann, Dr. Arthur V. Meigs and Dr. S. Weir Mitchell, censors; Dr. Thomas R. Nelson, secretary; Dr. Richard H. Harte, treasurer; Dr. Frederick A. Taggart and Dr. Elliston J. Morris, councillors.

Richmond (Va.) Academy of Medicine and Surgery.—At the annual meeting of the Richmond Academy of Medicine and Surgery at Richmond, Va., recently, the following officers were elected: Dr. Stuart McGuire, president; Dr. W. F. Mercer, first vice-president; Dr. J. M. Winfree, second vice-president; Dr. C. R. Robins, third vice-president; Dr. Mark W. Peyser, secretary; Dr. W. F. Parker, assistant secretary; Dr. E. J. Moseley, Jr., treasurer; Dr. M. E. Nuckols, librarian; Dr. J. S. Wellford, Dr. H. H. Levy, Dr. A. C. Palones, Dr. W. S. Gordon, Dr. J. A. White, and Dr. Landon B. Edwards, judiciary committee.

A Physician Stabbed by his Patient.—Dr. John H. Kellogg, superintendent of the Battle Creek, Mich., Adventist Sanitarium, was stabbed recently by a patient who had suddenly developed homicidal mania. The wound is reported as not being severe.

Defendant Doctor Wins Damage Suit.—Judge Somerville, in the Civil District Court at New Orleans, has handed down a lengthy decision denying the damages asked by Samuel Stern from Dr. Oscar Laang. The suit arose out of an operation performed on one of Mr. Stern's eyes by Dr. Laang. It was alleged in the petition that owing to negligence and want of skill the petitioner lost the sight of the eye by the treatment prescribed by Dr. Laang. For this the action of \$10,106 damages was brought. In the ruling it is held that the loss of the sight of the eye was not proved to have resulted from any fault of Dr. Laang, and accordingly the demand for damages was denied.

Physicians Sued by a Patient's Widow.—Mrs. Mary A. Sietz, of Seattle, Wash., widow of a laboring man who died last week after undergoing a surgical operation, is suing to recover \$15,000 from Dr. John Witherspoon, Dr. G. V. Calhoun and Dr. A. B. Bailey, alleging wrongful methods of treatment. The answers made by the defendants deny the allegations concerning improper treatment and surgery.

St. Luke's Hospital, Chicago, Sued.—A suit for \$5,000 damages has been brought in the superior court at Chicago against St. Luke's hospital, and against Dr. Henry W. Cheney and Dr. Louis B. Curtis, on the ground that the death of a patient, the child of the plaintiff, was caused by tetanus due to lack of care in the treatment given him while in the institution.

A Portrait of Dr. Leidy Presented to the College of Physicians.—Through the courtesy of Mrs. Joseph Leidy, Jr., of Philadelphia, a life-size oil painting of the late Dr. Joseph Leidy, fellow of the College of Physicians, president of the Academy of Natural Sciences, and professor of comparative anatomy and biology at the University of Pennsylvania, has been presented to the College of Physicians of that city. On the occasion of the presentation an interesting letter was read which had been written to Dr. Leidy by Professor Huxley.

The Lying-in Hospital of New York.—The annual report for the year ending September 30th has just been issued. The new hospital now in course of erection, the gift of Mr. J. Pierpont Morgan, is described. It is situated at Seventeenth and Eighteenth Streets and Second Avenue. The basement will be devoted to the outdoor work, the first story to the executive offices, the second to the nurses' department, the third to the septic department, and the fourth, fifth and sixth stories to wards for patients, consisting of about two hundred beds. The seventh story contains the operating room, laboratory, kitchen and laundry, while the eighth story is a continuation of the laboratory, with additional amphitheatre seats for the operating room.

The number of births in the Borough of Manhattan for the preceding year is stated as 50,472. The number of applicants to the institution were 3,018, of whom 2,162 were cared for, with only eight deaths. The Ladies' Auxiliary has rendered important service in supplying nurses, etc.

A Grateful Physician Remembers his Nurse.—The late Dr. F. B. Smith, of Philadelphia, in his will has bequeathed to Miss Margaret Coyne, of North Scranton, Pa., half of his \$80,000 estate. Miss Coyne is a graduate of the Training School for Nurses attached to the University Hospital. Her first patient was Dr. F. B. Smith. The case was one demanding skill and unremitting attention. Day and night Miss Coyne tended the sufferer, and after four months Dr. Smith recovered.

Medical Inspectors of Schools Organize.—The Philadelphia Association of Medical Inspectors of Schools recently effected permanent organization. The officers of the association are: President, Dr. J. H. McKee; secretary and treasurer, Dr. Frank C. Hammond. The executive committee consists of Dr. Charles A. E. Codman, chairman, with Dr. Charles A. Ayres, Dr. Truman Auge, Dr. George W. Bowen, Dr. William E. Robertson and Dr. Howard B. Martin. Meetings of the association will be held at least once a month, at which papers will be read and topics discussed having relation to school hygiene.

The Bertillon System for Classifying Diseases.—In adopting a report submitted by Dr. Roger S. Tracey, Register of Records, the New York City Board of Health decided recently to use the Bertillon system in classifying the causes of deaths in the Bureau of Records, after January 1. The Bertillon system adopted is not the Bertillon system of measurements as used by the police, but a system for the classification of diseases. It is intended to facilitate the gathering of statistics on diseases and causes of death so that they may be uniform all over the world. The system is now in general use abroad.

Eye Malady Epidemic in Chicago.—A new disease which attacks the eyes and in many respects resembles "pink eye" was recently reported epidemic in Chicago. It is infectious and is not confined to any particular part of the city or class of people. One explanation offered for the origin of the malady is that it is due to the clouds of dust driven about the streets since the windy season set in. The streets have been notoriously dirty, and even people not attacked by the disease have had reason to complain of the discomforts suffered by having their eyes filled with dirt. These dust particles are supposed to have caused inflammation which has developed an infectious affliction.

Baltimore's Sanitary Condition Said to have Caused Typhoid Fever Epidemic.—In eleven months 783 people have died of typhoid fever in Baltimore. The health commissioner blames the drinking water and lack of a sewage system for the prevalence of the disease, and he does not think conditions will improve until the city has a filtration system for the water supply. Other physicians say the sanitary conditions of Baltimore were never worse. Alleys all over the city are in a filthy state.

Medical Students Rebel.—Students of the Saginaw Valley Medical College, at Saginaw, Mich., recently held a mass meeting and decided not to attend lectures in consequence of a small-pox patient being confined in the college hospital. This decision was reached in the face of the announcement by the faculty that the lectures would be resumed.

Cuba Fairly Free from Contagious Diseases.—General Leonard Wood has written the following letter to the

adjutant general of the army regarding the sanitary condition of Cuba: "I desire to invite your attention to the sanitary situation now existing in Cuba in order that general public opinion in the United States may be corrected. The island is, as a whole, free from epidemic or contagious diseases at present, with the sole exception of Havana, where there still remain a few cases of yellow fever, though not enough to receive serious consideration.

The Death Rate in New York City.—The death rate of New York City in 1900 was 20.53 to the thousand, as against 19.47 in 1899, the increase being due to the epidemic of influenza in the spring and deaths from heat in the summer. During the first five months of the year the deaths were 4,987 more than in the corresponding period for 1899. There were 298 deaths from sunstroke, against 141 the year before, an increase of 50 per cent. in deaths from measles, 25 per cent. from typhoid fever, and 10 per cent. from diphtheria and croup, these later variations being regarded as normal. There were only twelve deaths from small-pox, against eighteen in 1899.

Report of New York State Health Board for 1900.—Dr. Baxter T. Smelzer, secretary of the State board of health, in his latest report, says that the work of the laboratory connected with the board has been of a larger volume than usual by reason of the great number of cases of typhoid fever. The disease in many instances was traced to the use of well water which had become contaminated. It is the hope of the board that in the near future the legislature will make a sufficient appropriation to warrant equipment with the necessary appliances of a modern laboratory and the employment of a sufficient force therein to do the work. The number of candidates who passed the State examination entitling them to operate as undertakers in 1900 was 121. During the past few years numerous complaints have been received by the State board of health concerning insanitary conditions existing at summer resorts, alleged to have caused typhoid fever and other diseases. In view of the results of the several investigations made, the board says that there is warrant for the recommendation that a general inspection of summer resorts be made by representatives of the board. During the year 160,000 certificates of births, marriages and deaths have been received for record and filing. There seems to be a laxity, says the board, on the part of clergymen and physicians, in reporting marriages and deaths to the boards of health of the municipalities in which the events occur. An increase over the \$35,000 appropriated for the expenses of the board is asked for.

The Bellevue Hospital Investigation.—As a result of the Bellevue Hospital investigations, Dr. George Taylor Stewart has been placed in charge of Bellevue, Gouverneur, Harlem and Fordham hospitals by the Commissioner of Charities. William B. O'Rourke, formerly superintendent of Bellevue, has been made deputy superintendent of that institution, and the present deputy has been transferred to Gouverneur Hospital. Dr. Stewart was born in New Milford, Conn., in 1855 and took his medical degree at the Hahnemann Medical College, in Philadelphia, in 1882. He was for a time connected with the Ward's Island Hospital, later studied abroad, and engaged in private practice in Mexico and California and returned to New York City in 1890. He has been at the Metropolitan Hospital, Blackwell's Island, since 1894, and has established the reputation of being a strict disciplinarian. A year ago he reprimanded an interne at the

Metropolitan Hospital, and, his associates siding with the physician reprimanded, he suspended the entire house staff consisting of twelve internes, who were subsequently discharged by the Commissioner of Charities. The appointment of Dr. Stewart was first submitted to the medical board of Bellevue and approved of by them. He is given ample authority over all employees of the department who are engaged at the hospitals under his charge. The Commissioner of Charities has discharged several additional nurses and twelve more have threatened to resign, making a total of forty-one nurses discharged or resigned from Bellevue since the beginning of the investigation out of the original number of seventy-two. The inspector detailed by the State board of charities to investigate the condition of Bellevue Hospital has reported to that body, condemning severely the general condition of affairs found at the institution, and concluding his report as follows: "Nothing, save a complete change throughout the staff of employees, will be satisfactory, for, with a few notable exceptions, inefficiency, callousness, and idleness characterize those who are employed to do the work of the hospital. The tests of efficiency and zeal, of character and sobriety, have not been applied, and it is by these that the new superintendent can make Bellevue what it should be—a model hospital. New buildings are needed, but a new spirit and motive far more." Commissioner Keller said of the inspector's report: "The report is all right. I am afraid that what he says is true, but it will now be remedied. That is all I have to say."

Changes at Bellevue Hospital.—A new ward, known as the tuberculosis pavilion, large enough for two hundred patients, was opened recently at Bellevue Hospital. Three graduate nurses will be in charge. Eight house doctors, each at the head of their division, completed their two years' practice at Bellevue on January 1st. The men who leave the hospital are Dr. Frank L. Christian, Dr. R. T. Joy, Dr. E. Sturge, Dr. J. R. Swanick, Dr. H. H. Pelton, Dr. L. C. Rice, Dr. C. G. Dougherty and Dr. G. F. Varhart.

A Dewey Sanitarium for the Consumptive Poor.—In a communication to the New York papers Dr. S. A. Knopf recently made the suggestion that the money which was collected for the purpose of erecting a permanent Dewey arch be used instead in the building of "The Dewey Sanitarium for the Consumptive Poor of the City of New York," such sanitarium to be situated in or near the city.

Columbia University Hospital.—The need of additional facilities for Columbia University Hospital, Washington, D. C., was strongly emphasized at the annual meeting. Officers were elected as follows: Dr. F. A. King, president; Rev. Dr. S. H. Greene, vice-president; Mr. S. W. Woodward, treasurer, and Dr. E. A. De Schweinitz, secretary.

State Consumption Hospital.—Dr. Willis G. MacDonald, of the board of trustees of the State Hospital for Treatment of Incipient Pulmonary Tuberculosis, has been designated to confer with State Architect Heins regarding the buildings to be erected in the Adirondacks, probably at Ray Brook. It is likely that the structure will be two-story, instead of one, as first proposed, and it will cost at least \$100,000. Its construction will be frame with a veneer of brick. An appropriation of \$100,000 more will be asked of the legislature this win-

ter. The cost of patients is estimated at \$7 each a week. The hospital is to have a capacity of 200.

A Proposed New Children's Ward at Randall's Island.—At a recent meeting of the health board a resolution that a new children's ward be established on Randall's Island, to be used solely for children afflicted with contagious diseases, was approved, and Dr. Jenkins, Dr. Cosby, and Dr. Roberts were appointed a committee to call on Commissioner of Charities Keller and confer with him.

The New Cornell Medical College.—The contract for the building of the new Cornell Medical College has been awarded by the board of trustees of Cornell University to Driscoll Brothers, of New York. The building, which will be situated on the campus, is to cost \$125,000. It will be situated next to the law college and will nearly complete the quadrangle. It is to be ready by the fall of 1902.

A New Hospital at Chicago is to be established under the auspices of the Sisters of Charity of St. Nicholas' German Catholic Church. The old Kirk homestead, at Ridge Avenue and Oakton Street, has been purchased by the Sisters for \$35,000 and will be remodeled for hospital purposes. The hospital will be the second in Evanston and situated in the opposite end of the city from the present hospital. The Kirk mansion was built at a cost of \$25,000.

Hospital Buildings and Endowments.—An effort has been made to secure from France an appropriation of \$50,000 for the French Hospital in New York City. Changes are contemplated that will cost about \$200,000. The plans will not be fully decided upon until enough money to go to work on the changes has been collected. The French Hospital now accommodates sixty patients. —The Beahan Hospital, of Canandaigua, N. Y. (a private institution), has been incorporated at Albany, with a capital of \$10,000. The directors are A. L. Beahan, M. R. Corson and O. J. Hallenbeck, of Canandaigua. —The State Board of Health and the Forest Preserve Board recently held a joint meeting at Albany to consider the selection of a site in the Adirondacks for the proposed State hospital for consumptives. The trustees have selected a second site at Raybrook, between Saranac Lake and Lake Placid, and not far from the Lake Clear site, which the trustees first selected and which developed such opposition that the Forestry Preserve Board and the State Board of Health did not approve of it. —In the will of Theodore D. Barnum, of Buffalo, N. Y., a bequest of \$500 is made to the Homœopathic Hospital of that city. —Dr. C. L. Bard and his brother, United States Senator Thomas R. Bard, are to erect a hospital at Ventura, Cal., in memory of their mother. The hospital will be a three-story structure and when completed will cost about \$15,000. It will be open to all regular physicians and surgeons and will eventually be presented to the city. —Funds for enlarging the St. John's Hospital in Woods Run, Pittsburg, Pa., have been raised by private subscription. A bid has been made for the purchase of property adjoining the present building, to cost \$9,000. When the new addition is completed there will be room for forty more patients, thus increasing the capacity to one hundred patients. —Work on the Herman D. Cable memorial addition to the Evanston Hospital at Chicago will shortly be begun. The money for the edifice—\$50,000—was given by Mrs. Herman D. Cable, widow of a piano manufacturer. —The Hospital of St. Vincent de Paul, at Norfolk, Va., which was partly

destroyed by fire in September, 1899, and has been reconstructed at a cost of about \$100,000, will be formally opened in January. —William C. Schermerhorn, second vice-president of the New York Eye and Ear Infirmary, at Second Avenue and Thirteenth Street, has presented to that institution \$75,000 to constitute a fund for the construction of a pavilion for patients afflicted with diseases of the ear. In the last five months the hospital surgeons have performed two hundred mastoid operations for intercranial diseases. It is for these cases especially that Mr. Schermerhorn intends the new pavilion. It will be the first of its kind. The structure will be of brick, five stories high.

Births, Marriages and Deaths.

Born.

CLOUD.—In Fort Sill, Oklahoma Territory, on Sunday, November 18, 1900, to Dr. M. N. Cloud, United States Army, and Mrs. Cloud, a daughter.

Married.

BUSHNELL—NEWLAND.—In Springfield, Illinois, on Wednesday, December 26, 1900, Dr. William K. Bushnell, of East St. Louis, and Mrs. Annie Newland.

CLARKE—BURDEN.—In New York, on Wednesday, January 2d, Dr. Alexander S. Clarke, of Paris, and Mrs. Daisy McCoy Burden.

ELAM—MYERS.—In Chicago, on Thursday, December 27, 1900, Dr. W. T. Elam, of St. Joseph, Missouri, and Miss Alice B. Myers.

HAYES—COLWELL.—In Providence, Rhode Island, on Tuesday, January 1st, Dr. Albert Edwin Hayes and Miss Fannie A. Colwell.

MASSIE—BECHTOLD.—In St. Louis, on Monday, December 31, 1900, Dr. J. G. Massie, of Belleville, Illinois, and Miss Adele F. Bechtold.

NORTHROP—WAGENSELLER.—In Kansas City, Kansas, on Wednesday, December 26, 1900, Dr. John F. Northrop and Miss Clara L. Wagenseller.

POPE—WIGHTMAN.—In San Francisco, on Tuesday, December 25, 1900, Dr. Saxton T. Pope and Dr. Emma Wightman.

RASIN—COBLENZ.—In Baltimore, on Tuesday, January 1st, Dr. Robert Cooper Rasin and Miss Anna Elizabeth Coblenz.

ROSS—FESSENDEN.—In Cherokee, Kansas, on Monday, December 31, 1900, Dr. Robert M. Ross, of St. Louis, and Miss Daisy Fessenden.

ROSWELL—READ.—In Woonsocket, Rhode Island, on Tuesday, January 1st, Dr. Joseph T. Roswell and Miss Harriet Read.

STEVENSON—SUNDERLIN.—In Dundee, New York, on Wednesday, December 26, 1900, Dr. George Stevenson, of Buffalo, and Miss Louise Sunderlin.

VAN ARSDALL—MAY.—In Kansas City, Kansas, on Wednesday, December 26, 1900, Dr. Alexander La Vere Van Arsdall and Miss Elizabeth Wolf May.

Died.

CLEMENTS.—In Chicago, on Thursday, December 27, 1900, Dr. H. C. Clements, aged fifty-two years.

COREY.—In Fort Scott, Kansas, on Tuesday, January 1st, Dr. Jay Corey.

HOWLAND.—In Flint, Michigan, on Thursday, December 27, 1900, Dr. George W. L. Howland.

JONES.—In Grass Valley, California, on Friday, December 28, 1900, Dr. William C. Jones, in the sixty-eighth year of his age.

NELLES.—In Thornhill, Ontario, Canada, on Saturday, December 29, 1900, Dr. David A. Nelles, in the forty-sixth year of his age.

RANKIN.—In Shields, Pennsylvania, on Tuesday, January 1st, Dr. David Nevin Rankin, of Pittsburg.

SCHNEIDER.—In Williamsport, Pennsylvania, on Saturday, December 29, 1900, Dr. Louis Schneider, in the fifty-sixth year of his age.

TARBELL.—In Boston, on Friday, December 28, 1900, Dr. George G. Tarbell.

Pith of Current Literature.

Medical News, January 5, 1901.

A Study of Eighty-one Cases Operated upon under Analgesia Obtained by Subarachnoid Spinal Cocainization. By Dr. George Ryerson Fowler.—Though the author's experiences with spinal cocainization have been generally favorable, he holds to the proposition that the ideal anæsthetic is one which, with absolute safety, will render the patient entirely oblivious, not only to the pain of the operative procedure, but to each and all of its disagreeable features as well. This is particularly desirable in surgical cases. In obstetrical practice, however, the patient is more or less prepared, by long looking forward, for not only painful, but disagreeable, and what under any circumstances cannot but be disgusting, features of the event.

The History, Aim and Purpose of the Medical Societies of the State and Counties of New York. By Dr. Frank Van Fleet.—Every member should have a feeling for his society and its constitution, second only to the reverence and admiration he feels for the United States of America and its constitution. The latter stands for the protection of the rights of man, while the former stands for the protection of the public health. Referring to the New York State Medical Association and its county branches, the author asserts that this organization has done, and is doing, its utmost to overthrow the Medical Society of the State of New York and its county branches. It represents a principle which is antagonistic to the medical laws of the State of New York, as well as to the spirit of the constitution of this State and of the United States. No more important subject will ever be brought before the people of this country than the subject of the proper regulation of the practice of medicine and the protection of the public health. The State of New York has placed this matter in the hands of the medical profession, and in accepting this trust the Medical Society of the State of New York and its county branches aim to so conduct themselves as to merit the approbation of all good citizens.

Pneumonia: Its Ætiology and Treatment. By Dr. D. L. Burnett.—The less often the word pneumonia is spoken in the sick room, the better will be the patient's chance of ultimate recovery. Though treatment does not shorten its course, the outcome of pneumonia is emphatically dependent on the treatment received. While lobar pneumonia is caused by the pneumococcus of Friedländer and the diplococcus of Fraenkel, bronchopneumonia is not thought to be so caused, but may be of a specific nature. As to treatment; an initial dose of a mild cathartic is indicated in ninety per cent. of all cases. After the bowels are thoroughly unloaded, the patient should be put well under opium for two or three days until the sudden shock to the nervous system is somewhat expended. Excessive fever should be controlled by cold sponging. The chief organ to watch is the heart, and a very serviceable combination is nitroglycerine, sulphate of strychnine, spirit of camphor, aromatic spirit of ammonia, and *spiritus vini gallici*, to which may be added an opiate if needed. Strychnine is often used with too much timidity. The patient should never be allowed to rise on his elbow to take nourishment or to cough. Insomnia should be met without a direct recourse to opium. One one-hundredth of a grain of hyoscyamine will often have the desired effect, especially if there is a tendency to delirium. Poultices properly made, and carefully at-

tended to, are of great comfort in the first stages and when there are sharp pleuritic pains or a harsh, annoying cough. Lime-water and milk is an old and valuable means of nourishment. During convalescence the keynote of the treatment is tonics.

On the Prognosis of Hysteria: A Contribution to the Question of Fatal Hysteria. By Dr. Joseph Fraenkel.—The author believes that when death occurs in hysteria it is due to irritation or paralysis of splanchnic or vegetative functions, and that a case of hysteria with more or less constant splanchnic or vegetative symptoms is from a prognostic standpoint, both as regards health and life, to be adjudged very cautiously.

Boston Medical and Surgical Journal, January 3, 1901.

Experiment and Experience with the Rifle. By Dr. Henry G. Beyer.—The author has written a very interesting and instructive article on this subject. When we consider that, at the battle of Colenso, in the Anglo-Boer War, 97.5 per cent. of all the wounds were due to rifle fire, the necessity for an intimate study of, and acquaintance with the work done by this wonderful piece of machinery should be evident to the surgeon. Much use is made of the work of Kocher on the subject, and the author points out that it was he [Kocher] who first proved by experiment and observation that every increase in the frontage or the cross area of the attacking surface of a projectile was followed by diminished penetration and increased explosive effect. The penetrative power of a bullet is primarily dependent on its velocity, next on its specific gravity, and, thirdly, upon its hardness or consistency.

In the heart, liver, intestines and bladder, the hydraulic effect begins to appear with velocities of about two hundred and fifty metres, and it depends upon the quantity of fluids which the tissues contain. As regards the benign character of abdominal wounds occurring in South Africa, Sir William MacCormac says, "I can only explain this considerable immunity by the frequently empty state of the intestinal tract at the time of the injury."

Clinical Notes and Comments: Degenerative Disease of the Spinal Cord Associated with Anæmia. By Dr. Robert T. Edes.—Certain cases showing fairly definite spinal symptoms on the one hand, and conditions of malnutrition of the blood on the other, were at first spoken of as spinal degeneration, dependent upon pernicious anæmia. The present tendency, according to the author, is to put the anæmia more or less into the background, and to speak rather of a toxæmia which may be the common cause of both conditions. The presence of such a toxæmia is rendered very probable by the sequence of the condition spoken of upon quite a number of infectious diseases. Which set of symptoms has existed at first cannot always be known, though the nerve symptoms are the first to attract attention. The early sensory symptoms are numbness in the extremities, inability to use the hands for fine work, and a sense of extreme coldness in the feet. The motor symptoms are those of general weakness of motion and coordination rather than of distinct paralysis of any group of muscles or special movements. Illustrative cases follow.

The Differential Diagnosis of Intestinal Obstruction. By Dr. Z. Boylston Adams.—The most important distinction from the point of view of treatment lies between strangulation and impaction or closure of the intestines occluding the lumen, whether from within or from without. When palpation under ether fails to disclose the nature of the tumor, the anamnesis is of importance.

The family tendency, the fact of injury or of surgical operations, of previous attacks, of hernias, of the ingestion of indigestible substances, should be inquired into. The clinical history should be carefully considered. Examination *per rectum* should never be omitted. The employment of purgatives or opium is unadvisable. Whenever the diagnosis of intestinal obstruction is made, a surgeon should be called to the case. The operation of coeliotomy, in experienced hands, is comparatively safe, and may be the means of saving many lives. The fatal result usually comes from overdistention of the gut above the seat of obstruction.

A Physiological Solvent in the Treatment of Pus Cases. By Dr. Carl E. Munger.

Journal of the American Medical Association, January 5, 1901.

Specialties and Specialists. By Dr. Joseph Zeisler.—The author asserts that specialties are the legitimate result of increased medical knowledge. While an enumeration of the present existing specialties may be starting, the general practitioner will always keep the management of acute diseases, and should be the trusted medical counselor of the household in everything pertaining to hygiene, sanitation, development of children, etc. The author insists that the specialist should not only have a most thorough preliminary education, and a broad, comprehensive medical training in college and hospital, particularly in pathology, but should also have devoted from two to four years to his special studies. He should never lose the intimate contact with general medicine. The author devotes some space to the consideration of the specialty of dermatology, its scientific and practical importance, and what it has done for medical science, and he asserts that there is need of more thorough instruction in medical schools in this particular branch.

Ætiology of Dysentery. By Dr. Simon Flexner.—The author is disposed to view tropical dysentery as consisting of a bacillary and amœbic form, separable in their early and later stages by their clinical histories, their ætiology and pathological anatomy. The view expressed by Shiga, to the effect that the bacillus isolated by him is the cause of the epidemic disease occurring in Japan, may be followed by the establishment of the same organism as the cause of other epidemics. The author's observations prove the wide distribution and pathologic activities of the organism as well as its relation with a certain class of dysenteries.

Notes on Tropical Dysentery. By Dr. John Herr Musser.

Case of Malignant Endocarditis, with Recovery. By Dr. N. S. Davis.—A hard and fast line cannot be drawn between simple and malignant endocarditis. Anatomically, they are identical. Those cases in which high fever seems to originate from endocarditis are usually called malignant. In the author's case there were none of the usual sources of infection, and he believes that the chronic gastritis present may have made infection possible. The patient in this case recovered. Recovery is very rare. Not much is known of treatment; though, in those patients who have recovered, the majority were treated with remedies believed to have some specific value in combating streptococous or staphylococous infection.

External Drainage of Lung Cavities. By Dr. Le Moynes Wills.—The author details two cases in which this procedure has been resorted to, and, while the results are

encouraging, further work along this line is necessary before we can come to a decision as to its availability.

Surgical Errors in Skiagraphy. By Dr. Carl Beck.—That skiagraphs are not always conclusive in estimating functional disability, and that some injuries require the greatest care and experience for their interpretation, are demonstrated by the author.

Walled Off. By Dr. John B. Deaver.—Pus is an avoidable complication in the treatment of appendicular inflammation, and the patient's welfare is best preserved by avoiding any of the complications incident to pus formation. The walled-off abscess is an evil to be avoided by prompt surgical intervention so soon as the symptoms of inflammation manifest themselves. Operation on cases of walled-off pus imperils the patient's chances for recovery, on account of liability to infection of the peritoneal cavity. Fæcal fistula as a result of a walled-off appendicular abscess is an avoidable sequel to appendicular inflammation and it should not be permitted to occur. The latter statement is true of all complications and sequelæ of appendicitis due to pus formation.

The Army Surgeon in the Philippines. By Dr. William J. Lyster.

A Normal Acoumeter. By Dr. E. Amberg.—The principle of this apparatus is an old one. A steel ball of a certain weight falls through a certain distance on a metallic block. Such an instrument, according to the author, excludes errors to a greater extent than Politzer's acoumeter does.

Amblyopia Following the Intoxicating Use of Jamaica Ginger. Subsequent Recovery of Vision. By Dr. Edward Steiren.

The Douche in the Treatment of Ophthalmia Neonatorum. By Dr. E. E. Holt.

Medical Record, January 5, 1901.

The Prevention and Relief of Postoperative Intestinal Obstruction. By Dr. Clement Cleveland.—The protection that the Trendelenburg position affords to serous surfaces is referred to. After operation there should be no raw surfaces; every stump or particle of raw tissue should be cauterized or covered with peritonæum. To leave the abdominal cavity half filled with decinormal salt solution on closing the incision is good practice. In addition to other advantages, the presence of the solution may lessen the amount of plastic lymph thrown out, and thus lessen the amount of adhesions. The author has been much impressed with the importance of the insufflation of oxygen gas as an agent of relief in this form of obstruction, and his results in several cases are given to illustrate.

A Case of Æstivo-autumnal Fever with Unusual Symptoms. By Dr. George L. Peabody.—The puzzling question in this case is as to the exact condition of the patient's spleen. It was absolutely immovable for several weeks, being always distinctly palpable, and temporarily imposing upon several who examined the patient, to the extent of causing them to consider it a tumor of the kidney. At present it offers nothing unusual to palpation in regard to its size, position and mobility. The presence of this form of malarial fever in this immediate vicinity is of interest.

Intestinal Indigestion. By Dr. A. P. Stoner.—The author combats the impression that disturbances of digestion in the intestinal tract invariably lead to catarrh and diarrhœa. Among the most prominent local symptoms

are a feeling of distress and an abnormal fulness referred to the hypogastric or gastric region, but without tenderness except upon deep pressure. There is a constant desire to eructate gas. Each case is largely a problem in itself, and must be treated individually. Most cases are caused by abnormal fermentation; therefore starches, sugars, and fats, should be interdicted, and proteids in the form of lean meats given. However, excessive amount of proteids may be the cause of the disorder, in which case all albuminous substances should be expunged from the diet list and some form of carbohydrates substituted. The author does not place much dependence upon predigested foods and artificially prepared enzymes.

On the Effect of Topical Applications of Excessive Strength and Improper Diet and Hygiene in Prolonging and Causing Skin Diseases in Infants and Young Children. By Dr. S. Sherwell.—As the gist of his experience, the author would recommend the milder measures, and the necessity of considering the individual case as to diathesis, etc., these all having a direct bearing on the treatment of any particular case. In internal treatment, not only in the subjects of skin diseases, but in all those in whom perverted metabolism and its results occur from abnormalities of secretion in the *primæ viæ*, the author prefers mercury with chalk in fractional or other doses. In any case, the remedy acts as mild stimulant of, and aid to, proper secretion in the glands and guts, and is as certainly to a large extent disinfectant and antiseptic.

The Clinical Value of the Heart Reflex. By Dr. Albert Abrams.—This reflex can be observed only with the aid of the Röntgen rays and is best produced by friction of the skin of the præcordial region by means of a rubber. The author regards the heart reflex test as pathognomonic and far exceeding all other methods yet recommended in distinguishing a dilatation of the heart from pericardial effusion. If, in a given case of cardiac dulness, we vigorously rub the skin of the præcordial region by means of a rubber, and note, after two minutes, a reduction in cardiac dulness, we are justified in concluding that we are dealing with cardiac dilatation and not with a pericardial effusion.

A Case of Perforating Gastric Ulcer. By Dr. A. B. Atherton.

Philadelphia Medical Journal, January 5, 1901.

A Physician's Holiday at Karlsbad. By Dr. James Tyson.—On the whole the life at Karlsbad is an ideal one, with just sufficient amusement, exercise and treatment to occupy the time pleasantly. The purposes of the treatment are: 1. To prevent the injurious consequences of a sedentary mode of living, or of one-sided muscular action. 2. Ailments and disorders of the "organs of movement." 3. Dilatation of the stomach and bowels, chronic constipation, enlargement of the liver, hæmorrhoids, neuralgia, writer's cramp and similar affections, chorea, cases of paralysis and weakness of various kinds. 4. Obstructions to the circulation of the blood, diseases of the heart and their attendant consequences. 5. Diabetes mellitus, uric-acid diathesis, gout, adiposity and chronic metal poisoning. The most suitable and the most popular months for visiting are June and July.

Primary Branchiogenic Carcinoma. By Dr. Fredrick Shimançk.—This is an extremely rare affection. Radical operations are impossible in many cases, treatment being limited to palliation and symptomatic treatment, curettement, chloride of zinc and cauterization.

The Resources of Modern Minor Gynæcology. By Dr. Augustin H. Goelet.—The author enters a protest against gynæcology becoming a surgical specialty, and asserts that there is much that we can accomplish by minor gynæcology, and that there are many gynæcological disorders that are curable by office treatment. Among our diagnostic resources he enumerates the microscope, uterine endoscope, cystoscope, the use of steel dilators, anæsthesia, and, finally, exploratory abdominal and vaginal section. The therapeutic resources are by no means limited, and he regards uterine irrigation as being one of the most important, because it is the only reliable method of cleansing the uterine cavity, and it affords the most effective method of application to the surface of the endometrium. Under the head of internal medication, he mentions a combination of bromide and potassium iodide as being particularly beneficial as a sedative for painful conditions in the pelvis, and for promoting absorption of inflammatory exudates.

The Home Modification of Milk for Infant Feeding. By Dr. L. Emmet Holt.

A Criticism of the Diagnosis "Composite Teratoma of the Ovary" Made in the "Pathological Report" of Dr. E. A. Jones. By Dr. S. W. Bandler.

Some Cases of Tetany in Infancy. By Dr. John Lovett Morse.—In every case but one [there are seven cases detailed], conditions were present evidently capable of causing toxic products, absorption of which into the circulation, with the resulting action on the nervous system, seemed to offer the most reasonable explanation as to the cause of the disease. The conclusion seems warranted that tetany is due to the action of the toxic products of many diseased conditions on the nervous system.

The Relation of State and Local Boards of Health to Outbreaks of Diphtheria. By Dr. G. E. Tyler.—Competent bacteriologic facilities should be offered free of charge to every citizen. Free antitoxine should be provided. If Pasteur's aphorism, "It is in the power of man to cause all parasitic diseases to disappear from the world," is true, there is need of greater ability in applying our present knowledge concerning this one. In small communities it is quite out of the question to maintain a public laboratory, and it then becomes the duty of the State board of health to supplement the local board by furnishing the necessary facilities.

Lancet, December 29, 1900.

The Association of Inguinal Hernia with the Descent of the Testis. By J. Langton, F. R. C. S.—The descent of the testis is a developmental process which exerts a dominant influence as a cause of hernia in infants, an influence, however, less powerful as age advances. The journey of the testicle from its original site of development below the kidney to its ultimate destination in the scrotum materially weakens the lower abdominal walls, and thus contributes in no small extent to the extrusion of some of the abdominal viscera, especially if associated with a congenitally elongated mesentery. Thus want of parietal integrity is chiefly manifested in the early periods of life, but the weakness left by the passage of the testis exists to a greater or less degree throughout life and thus acts as a predisposing factor of hernia at all ages. Inguinal hernia occurs eleven times more often in boys than in girls under the age of twelve months. Of 3,505 infants with hernia, 3,215 were boys and 290 girls. These numbers refer to the date of the first application of the patients for relief, and not to the date of the first discovery of the lesion. Inguinal hernia

in infant boys is three times more frequent on the right side than on the left, whereas in infant girls the two sides are nearly equal. This may be accounted for, firstly, in the structural weakness in the abdominal walls caused by the passage of the testis through them during intra-uterine life, whereby the walls are unable effectually to resist the constant pressure from within, and, secondly, to the failure in the perfect occlusion at birth of the processus vaginalis. Children born prematurely are very liable to hernia at birth, most frequently on both sides. Herniæ are largely associated with testes which fail to descend to their normal position in the scrotum (retained, partially descended, and ectopic testes), but instances frequently occur of testes permanently retained in the canal without a hernia. The author does not believe that such retained testes are specially liable to become the seat of malignant disease in later years. Misplaced testes should be classified as follows: (a) Complete retention within the abdomen; (b) retention within the inguinal canal; (c) placed outside the external abdominal ring; (d) situated high up in the scrotum, in the inguino-scrotal region; (e) placed in a skin pouch in the cleft between the scrotum and the thigh without any dartos tissue (cruro-scrotal testes, so-called); and (f) ectopic testes placed in unusual positions by the action of an errant gubernaculum in the thigh, perinæum or peno-pubal regions.

Congenital herniæ are classified as follows: 1. Herniæ into the cavity of the tunica vaginalis testis, which strictly includes the majority of so-called interstitial herniæ. 2. Herniæ into the funicular process which descend into the enclosed funicular process of the vaginal peritonæum. 3. Herniæ into a post-tunica vaginal sac, commonly known as infantile hernia, in which the protrusion is situated behind a dilated tunica vaginalis extending as high as the internal abdominal ring. The author discusses the anatomy and the relative occurrence of the above-mentioned three varieties of congenital herniæ, giving tables and diagrams. He pays special attention to interstitial herniæ, which he classifies as follows: 1. The hernia may ascend and separate the aponeurosis of the external oblique from the muscular internal oblique. This is the common interparietal or intermuscular form. 2. The hernia may split the aponeurosis of the external oblique from the outer ring to a variable distance, or it may pass through the external ring and take various directions. This is the pre-parietal or pre-aponeurotic variety. 3. The hernia may pass between the abdominal peritonæum and the fascia transversalis, lying in the sub-peritoneal fascia. This is the post-parietal, or post-muscular, variety.

In women interstitial hernia is probably due to distention of the abdominal muscles during pregnancy. Most of the cases are mothers of large families.

The Causation, Prevention, and Treatment of Post-partum Hæmorrhage. By Dr. G. F. Blacker.—The causes of post-partum hæmorrhage may be classified as follows: 1. Febleness, exhaustion or malnutrition of the patient. 2. Over-distention of the uterus and undue stretching of the uterine muscle, such as occurs in cases of hydramnios or multiple pregnancies. 3. Exhaustion of the uterine muscle from frequent child-bearing and prolonged labor. One of the commonest causes of post-partum hæmorrhage is the application of forceps and the delivery of the child when pains are absent and the uterus is exhausted—the so-called “temporary uterine inertia.” 4. Pathological conditions of the uterine wall, such as fibroid tumors, fatty degeneration of the uterine muscle,

etc. 5. Some mechanical hindrance to the contraction and retraction of the uterus, such as the retention of the placenta, or the presence of adhesions. 6. Too rapid emptying of the uterus, either by forceps or by version. 7. Extreme nervous depression and shock, such as follow the birth of a dead child. 8. The administration of chloroform has often been regarded as a cause of uterine inertia. 9. Deficient coagulability of the blood, as occurs in cases of septic infection and hæmophilia.

Prevention.—All patients should enter upon labor in as favorable a condition of health as possible, and attention should always be paid to the general health. Women with a history of hæmophilia should be given calcium chloride, in ten-drop doses, three times a day for the last weeks of labor. Medical attendance should be sent for the moment labor begins. Where hæmorrhage subsequent to delivery is feared, it is often wise to rupture the membranes even before the cervix is fully dilated. Uterine inertia, secondary to fatigue, should be recognized and the use of forceps avoided. Where the pains are feeble, large doses of ergot should be given. Post-partum hæmorrhage too often occurs as a sequel of hasty and premature attempts to deliver the placenta. No such attempt should be made until from twenty to thirty minutes after the completion of the second stage of labor. When post-partum hæmorrhage does occur the author recommends the following line of treatment. If the placenta is retained it must be at once expressed, or if this is impossible, removed by the hand. A hypodermic injection of ergotin may be given, and the uterus kneaded through the abdominal wall, while the nurse prepares a hot douche. If the hæmorrhage is profuse, bimanual compression may be necessary, until the hot douche is ready. In the small number of cases where the douche fails to excite contraction, recourse must be had to continued bimanual compression, to plugging the uterus with gauze, or the application of a styptic. As regards the hot douche, the water must be used in large quantities and at a temperature of not less than 117° F. to 120° F. The uterine tube should be carried up to the fundus; this is facilitated by drawing down the uterus with a volsella, which manœuvre alone sometimes serves to check the hæmorrhage.

Calcium Iodate as an Iodoform Substitute and Gastro-intestinal Antiseptic. By Dr. W. Mackie.—Calcium iodate is an iodine compound containing 51 per cent. of iodine and in addition 16 per cent. of available oxygen. On contact with putrescible organic matter, whether in acid or alkaline media, like other iodates, it slowly liberates iodine. It acts more as a destroyer of the products of bacterial life than as a bactericide of any decided degree of potency. But it does inhibit bacterial growth. It is prepared by mixing solutions of iodine and bleaching powder, when it crystallizes out as a white powder, which is both tasteless and odorless. The author gives the results of experiments to determine its potency, and also cites several surgical cases in which it was successfully used as a substitute for iodoform.

Circumcision as a Preventive of Syphilis and other Disorders. By E. H. Freeland.—The author holds that if it were possible to secure the efficient circumcision of every male in infancy, not only would many of the disorders incidental to the genito-urinary organs in childhood, adolescence, and adult life, be prevented, but also syphilis would be materially diminished. To bring this about it is necessary to show (1) that the operation is free from risk; (2) that the deprivation of the structure will not inflict any physical disability on the individual,

and (3) that the benefits which are likely to accrue are substantial and commensurate with the sacrifice. These questions the author answers *seriatim* and most conclusively.

On a New Method in the Dissection of Soft Cataracts. By P. Dunn, F. R. C. S.

A Case of Hydatids Primarily Affecting the Lung. By Julius Cæsar, F. R. C. S.—Hydatids primarily affecting the lung are very rare. The author reports such a case; his belief that the hydatids originated in the lung is based upon the following facts: (1) the liver was of normal size; (2) the hydatids could not have originated in the pleura, as there was no fusion of the costal and the pulmonary pleura; (3) there was no discoverable communication between the abdominal and pleural cavities; (4) the growth sprang from or was attached to the base of the lung. There was nothing in the history of the patient to suggest the source of the infection. Among the points of interest as regards diagnosis, were the following: (1) the very low temperature, which was never above 100° F., up to within a couple of days before death; (2) the character of the expectoration, with the well-defined streak of blood; (3) the intermittent and severe dyspnoea; (4) the diarrhoea; (5) the fact of the patient having years before suffered from drinking foul water.

Rhachitis and Ancient Medicine. By M. Armand Delpuech.—A historical paper.

Culture of the Germ of Soft Chancre.—M. F. Benzançon, M. V. Griffon, and M. L. Le Sourd report the successful culture of the bacillus of the soft chancre in gelatinized blood. The cultures appear in chains of different forms according as they are developed upon different media. Cultures from the pus of chancroid buboes can thus always be employed to settle a difficult or doubtful diagnosis.

Gazette hebdomadaire de médecine et de chirurgie, December 9, 13 and 16, 1900.

Herniated Appendicitis, Simulating Intestinal Strangulation.—M. Monchet reports such a case in which the vermiform appendix was found in a hernial sac. The symptoms were those of intestinal strangulation. Recovery followed the operation.

Abdominal Urticaria in Symmetrical and Segmented Bands.—M. Charles Achard reports two cases, one of the condition stated, the other of erythema of the thorax appearing in segments together with a pleurisy. The author thinks these cases prove the spinal influence of origin in these particular cases.

Purulent Rhinitis in the Course of Scarlatina.—M. Chausserie-Laprée speaks of different varieties of purulent rhinitis that may develop during scarlet fever, and suggests thorough irrigation of the nose in all scarlatinal cases as a prophylactic measure.

Tuberculosis of the Optic Thalamus. By M. Louis Spillmann and M. L. Nilus.

Progrès médical, December 8, 1900.

Chronic, Rheumatic, Suboccipital Arthritis.—M. Paul Coudray reports such a case which resulted in a permanent torticollis. The author advises in such cases *redressement forcé* under chloroform narcosis, to be followed by immobilization. Extension by the patient is then to be practised. The results in this case of this treatment were satisfactory.

Lyon médical, December 9, 1900.

Gastric Syndrome in Nurslings.—M. E. Weill and M. Péhu record two observations of a form of chronic dyspepsia in infants, characterized by regular, easy vomiting. The vomitus has no odor, no evidence of fermentation, and appears in from half an hour to an hour after feeding. No gastric dilatation or diarrhoea are present. The appetite is normal or exaggerated. No abdominal lesions can be demonstrated. There is a hyperacidity demonstrated by the vomited matter. The authors think a self-intoxication may be the basic ætiologic factor. They advise that alkalies be added to the milk.

Intestinal Ulcerations in Arteriosclerosis. By M. F. Mouisset.

Indépendance médicale, December 19, 1900.

A Case of Coxalgia. By M. Tillaux.

Treatment of Strictures by Linear Electrolysis.—M. J. A. Fort condenses in a short article the details of his treatment of urethral stricture by means of linear electrolysis by apparatus of his own devising. The patient is cured in three days, he says. The first day is devoted to the operation, the second and third days to antiseptic lavage and catheterization.

Wiener klinische Rundschau, December 16, 1900.

Questions in Light Therapy.—Dr. H. Strebel says that from a study of 324 cases of leucoplakia, the disease is principally found among men. It is caused mainly by syphilis and tobacco, and when luetic in its nature, is a parasymphilitic disease. About thirty per cent. of the cases become cancerous and the disease is exceedingly refractory to antisymphilitic treatment. The prognosis among syphilitics is bad, as many of them die of buccal cancer following leucoplakia.

Ætiology of Early Ulcerating Syphilide. By Dr. Jaroslav Bukovsky. (*Continued article.*)

On Aspirin. By Dr. Ludwig Müller.

Wiener klinische Wochenschrift, December 6, 1900.

Treatment of Peptic Ulcer of the Stomach.—Professor Anton Gluzinski, in an elaborate article, considers the various methods of treatment. He speaks of the difficulty of exact diagnosis as to whether hæmorrhage comes from an ulcer or from an eroded artery. Some cases should be treated prophylactically, so far as bleeding is concerned; one or two years' careful internal treatment subsequently, achieves excellent results. Cases with disturbed gastric motility usually represent the later stages of the disease, and are due, not to atony, but to pyloric stenosis. These cases must be treated by diet, by efforts to rid the stomach of its contents and by attempts at reduction of acidity. If the stenosis is not functional, but actually cicatricial, surgical measures constitute the treatment. Even after the relief of the stenosis, treatment must be vigorously continued. Perforation of an ulcer demands immediate surgical intervention, even though the result may be doubtful on account of the usual posterior location of the ulcer and the usual severe hæmorrhage.

Blood Pressure in Relation to Lymph Circulation.

—Dr. Friedrich Friedmann reports a case of lymphæmia with cardiac insufficiency, in which after prolonged administration of digitalis, the hugely enlarged lymphatic glands in the neck became very small, while those in the axilla and other parts of the body lost the greater part of their increase in size. At the same time, the lymphocytes in the blood increased. The author attributes these phenomena to the increased blood pressure caused by the digitalis.

Phlegmonous Appendicitis as a Sequel to Tonsillitis.—Dr. R. Kretz reports such a case.

Remarks on Ureteral Fistulæ. By Dr. K. Büdinger.

Wiener medicinische Blätter, December 20, 1900.

Treatment of Persistent Dropsy.—Dr. Alfred Roth considers the various phases of treatment in dropsy due to heart or kidney disease. Withdrawal of unnecessary fluids, and diaphoresis and diuresis constitute the main

elements of treatment. Diuretin, caffeine, sparteine, strophanthus, calomel, squills and digitalis are the drugs recommended for diuresis, while hot-air baths and pilocarpine, sometimes Nauheim baths, are advocated to bring about diaphoresis.

Pathological Anatomy and Clinical Varieties of Myocarditis (*continued article*). By Dr. J. Wahringier.

St. Petersburger medicinische Wochenschrift, December 8, 1900.

Spontaneous Cure of Ectopic Gestation.—Dr. A. Kupffer reports the case of a woman with a typical history who refused operation. Some months later, a foetal bone was passed by way of the rectum and at this time the gestation sac could be plainly felt behind the symphysis. At various times foetal bones passed away by the rectum and at one time considerable purulent fluid escaped by the same route. Three years later, the patient was perfectly well. Bimanual examination disclosed several sears in the fornices, and a tumor, sensitive to pressure, could still be detected behind the symphysis pubis.

Schneider's Dry Hæmatogene. By Dr. E. Sommer.

Centralblatt für Bakteriologie, Parasitenkunde und Infektionskrankheiten, November 30, 1900.

Ætiology of Tropical Dysentery. Dr. Simon Flexner concludes from his studies in Manila that tropical dysentery is a bacillary and probably an amebic form of the disease. The disease may be acute or chronic, the latter presenting a different pathological picture from the variety hitherto known as "amebic" dysentery. The bacillary disease offers a micro-organism which is morphologically, culturally, and pathogenetically like that held by Shiga responsible for the epidemic dysentery of Japan. They are probably identical, and the bacillus dysenteriae has undoubtedly a wide distribution in Nature.

Diphtheria in the Horse.—Dr. Louis Cobbett believes from his studies and experiments that horses are susceptible to diphtheria and may help to spread the disease.

New Form of Infectious Pulmonary Disease in Guinea-pigs. By Dr. F. Strada and Dr. R. Traina.

Changes in Anthrax Bacilli in Putrescent Cow's Blood.—Dr. E. Berndt has placed cultures of anthrax bacilli in cow's blood, which, after removal from the body, was allowed to putrify at room temperature. Bacilli could be demonstrated for thirteen days. Their death seems to begin in the centre, losing the staining power first.

Blood Filariae Transmitted Entirely by Insect Bites.—Professor Grassi and Dr. Noè show experimentally, in a preliminary communication, that the filariæ the embryos of which circulate in the human blood, are deposited there invariably by insect bites, just as the plasmodium malariae is deposited by the mosquito.

Three New Cestodia from New Guinea. By Dr. St. von Ratz.

Berliner klinische Wochenschrift, December 10, 1900.

Scrofula and Tuberculosis in their Relation to Con-junctival Tuberculosis. By Dr. W. Uhthoff.

Functional Ability of the Fatty Heart with Aortic Insufficiency.—Dr. Arthur Hasenfeld has performed a number of experiments to determine this point. He employed phosphorus to induce acute fatty degeneration and hypertrophy of the cardiac muscle. His studies

show that animals so poisoned, can withstand aortic insufficiency much more poorly than normal animals. He also finds that a hypertrophic heart with aortic insufficiency is somewhat prone to fatty degeneration. Moderate degrees of acute poisoning influence the strength and functional power of a hypertrophic cardiac muscle, whether in ordinary or extraordinary labor. Extensive acute fatty degeneration leads to diminished strength of a heart affected with aortic insufficiency, or it may even produce death.

Attempted Cure of Hernia of the Lung.—Dr. Oscar Vulpius describes the case of a man who suffered severe crushing injury of the right side of the chest, eventually resulting in a hernia of the lung at the site of the third rib. By resection of the second, third and fourth ribs an attempt was made to reduce the hernia. It proved unsuccessful owing to the large size of the prolapsed area of lung; but the author believes it might have had a different result had it been undertaken earlier.

Dietetic Treatment of Gastric Hyperacidity.—Dr. E. von Sohlern, on theoretical grounds, has long been using the carbohydrates in this condition of the stomach with gratifying results. He has now entirely discarded the exclusive meat-diet.

Diabetes Mellitus.—Professor Carl von Noorden says that the century has not produced any single drug which has a decidedly curative effect in diabetes. He speaks lightly of several vaunted remedies, and says that their virtue lies in the fact that patients are kept upon a strict diet at the same time that they receive the drugs. (*Conclusion*).

Deutsche Medizinal-Zeitung, December 17, 1900.

Problem of Malaria Therapy.—Dr. A. G. Cipriani recommends very highly the following formula in all forms of malarial fever, malarial cachexia, or other forms of malarial disease:

R Eosolic quinine.	} of each 7.5 grains;
Reduced iron.	
Strychnine sulphate.	} of each 1.5 grain.
Arsenious acid.	
Extract gentian.	q. s. to make 50 pills.

M.

The dose is two pills three times daily at mealtime; for children, from one to two pills daily. The same pills were found very useful in anæmia and chlorosis. Eosolic quinine is the neutral quinine salt of trisulphoacetyl creosote.

Deutsche Aerzte-Zeitung, December 15, 1900.

Treatment of Spasm of the Glottis.—Dr. Fischbein believes that this condition in children is due to a self-intoxication which arises by irritation of the peripheral ends of the vagi through toxins developed in the intestines. He gives a purge at once, takes away milk from the diet and substitutes gruels. He believes a good many cases arise from impure milk.

Hedonal, a New Hypnotic.—Dr. Wedekind says that this drug is of excellent hypnotic power, does not diminish the blood-pressure and does not evoke a drug habit. It has a slightly disagreeable taste. The drug is not very soluble and cannot, therefore, be given subcutaneously. The dose is from fifteen to thirty grains, taken dry on the tongue or in wafers. It is contraindicated in alcoholics, and in diseases which produce præcordial pain and dyspnoea.

Schneider's "Hæmatogene." By Dr. E. Sommer.

Klinitchesky Journal, November, 1900.

Two Cases of Operative Treatment of Cortical Epilepsy. By Dr. M. A. Luntz.—The author reports two very interesting cases in which Wagner's method was used in order to expose the cortex of the motor area and to remove, if possible, whatever lesions would be found. The first patient was a woman aged fifty-three years with a typical history of epilepsy. Her attacks began by twitching of the left lower extremity. The contractions gradually spread and the patient lost consciousness when the upper limb became involved. All methods of treatment were found to be of no avail. There was no history of syphilis, but scars were found in the region of the shoulder joint, and the patient related that she had suffered for a long time with a suppurative process in the shoulder. The author concluded that this process was probably tuberculous, and thought that the epileptic phenomena might possibly be due to tuberculous deposits in the motor area. Accordingly, an operation was decided upon. After shaving and disinfecting the scalp, the Rolandic fissure was located according to the method of Poirier, and the location tested according to Bennel and Godlee's rule. The osteoplastic resection of Wagner was then performed, the size of the bone-periosteum-skin flap being 7 by 5 centimetres. The flap was everted after severing the bony base with a fine saw, and the dura was found adherent to the bone for a distance of about three centimetres in the region of the upper third of the central convolutions. The dura was then incised for a distance of six centimetres, and it was found adherent to the cortex in the region mentioned. The cortex was not altered in any way, except by adhesions, as stated above. A scalpel was thrust several times into the cortex in the upper portion of the central convolutions, and no resistance was encountered, nor was any empty space felt or any fluid discovered. The adhesions were separated, the opening in the dura was sutured, and the bone flap replaced. The postoperative period was uneventful. The epileptic convulsions disappeared and during three months and a half after the operation the patient had only one mild attack of twitchings in the left leg, without loss of consciousness. The general condition of the patient remained the same, however. She was weak and complained of occasional headache and noise in the ears. A slight paresis of the right foot, which existed before the operation, remained unchanged.

The second patient was a woman, aged twenty-two years, who denied syphilis and alcoholism, but gave a history of epilepsy. At first she suffered from severe headaches; then came attacks which began with twitchings of the right side of the face. She had the appearances of optic neuritis in the fundus of the eye, and a difficulty in speech was noticed. These symptoms made the author think of a new growth, but the nature of the growth could not be stated. There was no history of syphilis and antisyphilitic treatment was of no avail. Tuberculosis was also a possibility, but there were no indications in that direction. The operation was performed essentially in the same manner as in the first case. The result was not satisfactory. Complete aphasia set in at first, and there was an increase of the paresis of the right upper extremity which had been very slight before the operation. The attacks of convulsions were absent for a short time only, and returned with the same intensity and frequency as before. The aphasia and the paresis disappeared to a certain extent when the patient was discharged, but the difficulty in speech was worse than before the operation. The lesions found in this case were as follows: The dura and pia were adherent to the subjacent cortex in the re-

gion of the Rolandic and Sylvian fissures. On removing the adhesions and lifting the membranes, a focus of nodules of the size of a cherry-pit with a grayish, softened centre, was found in the region of the lower part of the central convolutions, particularly the anterior, and encroaching upon the third frontal. Immediately behind the posterior central convolution there was a second focus of the size of a pea. These foci were removed with a scalpel. Microscopic examination showed that these lesions were tuberculous.

Concerning Corset Liver. By Dr. G. A. Leventhal.—The author gives a comprehensive review of the subject of corset liver and reports a case in which corset pressure produced a very pronounced lobulation of the liver, giving rise to a tumor in the abdomen. A pronounced corset liver occurs, according to Leue, who examined 3,184 cadavers of persons over sixteen years of age, in 25.3 per cent. of women and in 1.9 per cent. of men. Quincke gives the percentage of corset livers in women as 56.3 per cent., in men as 5.7 per cent., but his figures include cases in which there is only a furrow in the liver substance due to tight lacing, in addition to those in which there is pronounced corset liver.

The term "corset liver" is not exact, for furrows may be the result of tight lacing without corset, *e. g.*, by any form of belts, petticoat-strings, or other constrictions about the waist. The author agrees with Langenbuch and Thiersch that a corset which is not tightly laced rather protects the abdominal organs from the still more injurious effect of the tight waistbands. The latter are especially injurious in cold weather when the weight of heavy skirts is added to the compression. In these cases the corset becomes a *point d'appui* which supports the weight of the heavy clothing. The author analyzes the classification of corset liver as adopted by Hayem, by Quincke, and other authorities, and reports the case of a Russian peasant woman, aged twenty-seven years, who gave the following history: She lived in the country until her seventh year, then in Moscow. Until her fifteenth year she wore a waist with whalebone supports; after fifteen and until twenty years of age, the long corset. She rarely laced excessively. When she became pregnant for the first time seven years ago she substituted tightly drawn waistbands for the corset, and resumed the corset after labor. She entered the hospital complaining of severe cough, dyspnoea, weakness, and vertigo. On examination she was found to be a poorly nourished woman with a thorax paralyticus, *i. e.*, an evenly constricted lower portion of the chest (Quincke). Tuberculosis of the right apex, Koch's bacilli in the sputum. The right upper portion of the abdomen was more prominent than the left, and palpation in this region revealed a smooth, hard, triangular tumor which disappeared into the hypochondrium. The lower edge of the tumor was sharp and movable upward, but no sulcus could be distinguished. The liver dulness was continuous with that of the tumor. The diagnosis of corset liver was made by excluding all other causes of liver tumors. In moderate cases of corset liver no treatment is necessary. If perihepatitis, chronic congestion, or complicating affections of the gall-bladder or ducts occur, as they frequently do, the condition present must be treated. Landau recommends the wearing of elastic abdominal belts, but Langenbuch does not think this measure effective. Good results have been obtained by Billroth and Tscherning (Czerny?) by ventrofixation of the floating lobe. Resection of this lobe has been successfully performed by Langenbuch. The chief point is prophylaxis—reform of woman's dress.

Concerning the Œdema of Bright's Disease. By Dr. I. Kabanoff (*concluded*).—The lymph exchange of the skin depends upon a series of factors: 1. The secretion of lymph. This is increased when the activity of the kidneys is lowered, as in toxæmia, in acute or subacute infection of the kidneys. 2. The condition of the circulation in the skin—the peripheral resistance. More lymph is secreted when the pressure is high, less when there is arteriosclerosis, with atrophy of the skin and empty capillaries. 3. The vital energy of the skin cells, as reflected in the function of perspiration. 4. The circulation of the lymph, depending upon the condition of the heart and blood-vessels. In pure parenchymatous nephritis the conditions are most favorable for a marked general œdema, and it is in this form of Bright's disease that we meet with the most marked cases of disturbance of lymph circulation. The occurrence of œdema in Bright's disease therefore depends upon a series of external factors, *e. g.*, cold, exogenous toxæmia, etc. Internal factors, however, are the most important ones in all cases, and as the basis of these there are inherited or congenital peculiarities of the organism as a whole, and of the vital organs in particular. The author adds that his conclusions need further testing by physiologic experiments and by clinical observations.

Vratch, November 18, 1900.

Should Exudative Pleurisy be Treated with Drugs Only? By Dr. S. V. Levaschoff.—The author gives his experience with various drugs employed externally and internally in serous pleurisy. In eighty-two cases thus treated he has not seen any improvement from the use of the various cathartics, diaphoretics, diuretics, cardiac stimulants, etc., nor from the application of cantharides, iodine, or iodine mixed with guaiacol. He does not think that these external remedies can have any effect on the absorption of the exudate, and frequently the only results from the use of iodine solutions are severe blistering and desquamation of the skin. He found, however, that these counter-irritants were very efficient, so far as allaying acute pain was concerned. The author's view concerning the inefficiency of cathartics, diaphoretics and diuretics is supported by the testimony of many modern observers in England, Germany and France. The author concludes that the ancient method of treating pleuritic exudates is not to be relied upon. As regards salicylates, he began using these drugs in the eighties and has found that they are the only class of remedies that can be said to be of value in causing the absorption of pleuritic exudates. They may be used in mild cases with small quantities of serum in the pleura, with the expectation that they will arrest the inflammatory process and cause the absorption of the exudate. Too large doses should be avoided, as they are not more efficient than doses of medium size. If the salicylates fail to give favorable results within from fourteen to twenty-one days, their use is to be discontinued, the serum evacuated by puncturing the pleural sac, and the effusion replaced by some neutral fluid. Salicylates will be sufficient in about one third of the cases; the remainder must be treated by puncture and evacuation. There are a number of cases, however, which tend to get well spontaneously, simply with the proper mode of life and with the removal of all influences increasing the effusion. Therefore, all observations concerning the value of a method of treatment in pleurisy with effusion must be made after waiting a sufficient period of time to see whether the effusion does not tend to disappear of itself.

Phototherapy in Surgery. By Dr. Minime.—In a previous article the author called attention to the anæsthetic and absorbent qualities of blue electric light, even when obtained from such a weak source as a sixteen-candle incandescent lamp surrounded with blue glass and provided with a reflector (see *Revue internationale d'électrothérapie et de radiothérapie*, July, 1900). Chronic inflammations are less readily affected by blue light than acute processes. Hæmorrhagic effusions are more readily absorbed on the second or third day after their appearance than at the beginning. In chronic eczemas, blue light is worth using, especially in cases of so-called nervous eczema. The author reports a case of facial eczema in a man in which illumination with the blue lamp for ten to fifteen minutes every other day, the lamp being held at right angles to the skin and about seven or eight inches from the surface, gave very good results. After the third sitting, the itching and pain became less severe, and the skin lost its pronounced hyperæmic color. The skin was perfectly normal after the eighth sitting. In hæmorrhagic effusions due to traumatism, two or three minutes of blue illumination are sufficient to diminish the pain, and the effusions are very rapidly absorbed under the influence of this mode of treatment. The author reports two cases to illustrate this point. In his hospital the treatment of ecchymoses is as follows: A warm general bath is given and the extremity, if injured, is raised. Blue light is then applied. Occasionally warm compresses of one-per-cent. solution of boric acid and alcohol are added. In ecchymoses of moderate size the effusion disappears in from one to three days. Two cases of this kind are reported as examples. The author also thinks that light very readily penetrates into the stomach and the intestines. He reports a case in which he arrested vomiting by illuminating the stomach through the abdominal wall. In another case persistent hiccough was also arrested in the same way. He suggests that illumination be tried in vomiting of pregnancy. Effusions into the joints are very markedly influenced by illumination. Articular rheumatism, articular neuralgia, intercostal neuralgia, and coccygodynia have also been successfully treated by this method. The author reports a case of uric-acid deposits in the basilic and cephalic veins extending from the fingers to the axilla in a woman aged sixty-five years. After five sittings with the blue lamp the deposits disappeared. Inflammatory infiltrations are very easily treated by means of blue light. The swelling and painfulness of the spermatic veins which follow Bassini's operation for hernia are removed in a few sittings by this method. The author concludes that the analgetic effect of blue light and the absorbent action of this method of treatment are more rapid and efficient than any other therapeutic measure known.

Annals of Surgery, December, 1900.

Structure, Fracture, and Refracture of the Patella.

By Edward M. Corner, M. B., B. C., F. R. C. S.—The author directs attention particularly to the aetiology of these fractures. In quadrupeds, the patella is practically never broken, for though it bears a constant strain it is a strong bone. In man, in consequence of the erect position, the body-weight is transmitted directly from the femur to the tibia, leaving the patella comparatively functionless and hence weak. When the patella is struck, the femur acts as an anvil, and a stellate fracture results if the anvil is rendered firmer by the circumstance of the knee being bent. If the force area is greater than or equal to the

contact area a stellate fracture will result. If the force area is less than the contact area a transverse or oblique fracture results. The lower half of the patella is weaker than the upper, and statistics demonstrate that fractures about the centre and lower half of the bone form about eighty-three per cent. of all cases. The influence of contact areas upon the lines of cleavage has much to do with the causation of fractures. The liability of the male to fracture of the patella reaches its maximum at the ages of from thirty-five to forty years. The years of maximum liability in the female are from thirty to thirty-five. The percentage of cases in which refracture occurs is 13.5. Osseous union as a result of the operation of wiring seems now to give the best results. The osteogenetic powers of the patella are comparatively small, and no bony union will occur unless there is close approximation of the fragments.

Suppurative Pericarditis and its Surgical Treatment, with an Analysis of Fifty-one Cases Reported in Literature. By Dr. Charles Burnham Porter.—As a result of his study, the author concludes that pericardotomy is indicated in all cases of suppurative pericarditis. Because of the uncertain and varying relations of the pleura, and because of the anterior position of the heart whenever the pericardial sac is distended by fluid, aspiration of the pericardium is a more dangerous procedure than open incision when done by skilled hands. Incisions of the pericardium can be done quickly and safely by resection of the fifth costal cartilage, and in many cases under local anæsthesia. In many cases of serous effusion, open incision without puncture will offer less risk and speedier cure than aspiration. The method and detailed technique of the author, proposed in 1897, have been followed out by the majority of recent operators.

The Radical Cure of Inguinal Hernia in the Female.

By Dr. William B. Coley.—While most authorities agree that inguinal herniæ in women and children are more amenable to cure by mechanical treatment, the author's experience has led him to believe that the difference is very slight. As to the opinion of Kelly, that removal of the sac is of little importance, the author believes such an opinion erroneous. The transplantation of the round ligament is never indicated. In the author's cases—one hundred and twenty-three in number—the method employed was Bassini's, the single step of transplanting the cord being omitted. Rubber gloves are advocated by the author, and in support he cites the bacteriological findings in thirty-five examinations of the nails and hands of surgeons. Of sixty-eight cases in which portions of the skin were removed from the field of operation just before the primary incision was made, fifty-three were found to be sterile. Chromicized catgut or tendon may be rendered perfectly sterile, and the author prefers it to silk, silver wire, or silkworm gut. In the operation itself the cutting of the internal oblique muscle is not only unnecessary, but likely to weaken the canal. There has been no mortality in the author's cases. Seventy-three patients were under fourteen years of age, and fifty were between fourteen and seventy years. In eight cases suppuration occurred, limited to stitch-hole infection. The average time in bed was eight days, departure for home was permitted in two weeks, and a spica bandage was kept on for two weeks longer. Not a single relapse has been observed. The prognosis, from these notes, would seem to be better in the female than in the male. In 545 cases of inguinal hernia in the male, operated upon after Bassini's method by the author, there have been six relapses.

Echinococcus Cyst of the Liver. By Dr. Russell S. Fowler.—In the production of an echinococcus cyst, the exciting cause is the *Tania echinococcus*—a parasite that has its habitat in the upper portion of the small intestine of dogs. Introduced into the intestinal canal of man, the ova undergo partial development. Digestion destroys the covering of the ovum and its contained scolices are liberated, burrow into the intestinal wall, and thus enter the circulation. Should they, as is commonly the case, enter a radicle of the portal vein, they are carried to the liver. Here, or in other tissues, cysts are formed in the immature, or cysticercus, stage, and are known as hydatids.

The contributing cause is close companionship with dogs. The symptoms are due to pressure effects. Most frequently the tumor will be found springing from the inferior surface of the liver. The posteriorly placed cysts are the most difficult of detection. Untreated, the disease may progress indefinitely or death may occur from intercurrent disease; a spontaneous cure may be effected or death may ensue in a variety of ways. Their growth is very slow, as a rule. Modern treatment consists in the stitching of the sac wall to the edges of a wound in the abdominal parietes and then incising it in one or two stages. The cyst may be best reached in certain cases by the transpleural route or through the lumbar region. Aspiration lessens sac tension. Keep the fluid out of the peritoneal cavity. The healing may take many months. A liver fistula may persist indefinitely.

A Complete Series of Clinical Charts for Keeping the Records of Surgical Cases. By Dr. Charles H. Frazier.

Result of Operation for Cancer of Penis. By Dr. Nathan Raw.—Although the penis was removed at the level of the abdomen, it was still cancerous; so, a deeper dissection was made and each crus detached from its corresponding pubic ramus and cut off. The wound healed by first intention. The patient passed urine through a catheter for twenty-four hours, when it was removed, and he afterwards passed water voluntarily and with complete control of his bladder. Cure was complete in a month, and eight months afterward there was no sign of recurrence of the growth. Microscopically, the growth was an epithelioma.

Fracture of the Spine. By Dr. Walter Lathrop.—In partial lesions we should operate. Where the lumbar region is involved with lesions of the cauda equina, operation offers the best chance for recovery. In fracture of the spinous process, laminae, or entire neural arch, *operation is demanded*. Should immediate operation not be done, and we wait for from six to eight weeks, with the result that paralysis of the bladder and bowel continues, with cystitis and severe bed-sores present, we may be sure that Nature cannot relieve the case, and an operation is not only indicated *but demanded*.

Transperitoneal Urethrolithotomy. Report of a Case in which the Stone was Located by the X-Ray. By Dr. George N. J. Sommer.

Letters to the Editor.

ECHINOCOCCUS DISEASE IN THE UNITED STATES.

BERLIN, December 9, 1900.

To the Editor of the *New York Medical Journal*:

SIR: In a recently received article by Dr. Cary and Dr. Lyon, of Buffalo, entitled Primary Echinococcus

Cysts of the Pleura,* which bears the marks of much painstaking work, I notice the following statement (page 9):

"Hooklets were mentioned in only seven out of the sixty-seven cases of hydatid disease collected by Sommer (2) from the United States."† This statement is somewhat ambiguous. In the first place, it suggests that I collected sixty-seven cases of hydatid disease, an ambiguity which would have been avoided by the addition of the word "literature" after United States, as in reality I gave but few cases not already reported in the literature by other authors, by Osler especially, who in turn had also extracted his cases from the literature. Further, I really collected one hundred cases in man, published respectively thus: Sixty-seven in the *New York Medical Journal*, November 23, 1895, and thirty-three cases in the *New York Medical Journal*, August 26, 1896.

Of a publication in the *Medical Record*, November 23, 1895, I have no knowledge. What the percentage of "hooklets found" in the thirty-three cases was, I do not remember. It is regrettable that the "hooklet statistics" are weakened in usefulness owing to the fact that the hooks were not always looked for by the observers.

It will be remembered that Osler's statistics included Canada, whereas I purposely confined myself to the United States. Incidentally, I wish to add that I endeavored to make statistics for Mexico by cooperation with a Mexican colleague of high professional position, but without success, I regret to say, as especially in that land is the contact with dogs very intimate. Whether the Mexicans have a Bureau of Animal Industry, I do not know, but the investigation of echinococcus disease in Mexico should be a field of work for some investigator. Van Cott's case, reported by me in 1896, occurred in a Mexican. Whether the geographical source of infection in that case was determinable, I do not know.

H. OTTO SOMMER, M. D.

JOHIMBINE AS A REMEDY.

NEW YORK, December 24, 1900.

To the Editor of the *New York Medical Journal*:

SIR: Your column entitled Therapeutical Notes has always seemed to me one of the most attractive departments of the *Journal*, and I rarely let a week pass without eagerly reading the paragraphs on advances in therapeutics which appear under this heading.

In your issue of December 22, 1900, page 1096, there appears a brief paragraph in the department of Therapeutical Notes, concerning the treatment of impotence. Quoting from Mendel (*Therapie der Gegenwart*, July, 1900), your contributor says: "'Johimbin' (whatever that may be) has given the best results in the author's hands." I feel that the subject is of sufficient interest to render an explanation of the nature of johimbine worth printing, and therefore write what I can gather from my reading concerning this remedy.

Johimbine is an alkaloid which was first isolated in 1899 by Spiegel and Thomson, working independently but simultaneously, from the bark of *Yumbehoa*, or *Johimbehe*, and is said to be a most efficient and at the same time a harmless aphrodisiac. In addition to Mendel, whose recent article on the subject is quoted by your

*Excerpted from the *Transactions of the Association of American Physicians*, Vol. xv, 1900.

†(2) Echinococcus Disease in the United States. *Medical Record*, New York, November 23, 1895."

contributor, the action of this alkaloid has been tested on the generative organs of animals by Oberwirth, and in a recent article in the *Berliner klinische Wochenschrift* (1900, No. 42) A. Loewy, of Berlin, gave some very interesting details concerning the action of this drug. He found that hypodermic injections of johimbine into rabbits produced a marked hyperæmia of the epididymis, the testes, and the penis, as a result of which an erection followed. No irritating effects on the kidney were observed. In men, the internal administration of johimbine in doses of five milligrammes, two or three times daily for two or three weeks, had no injurious effects upon the kidneys, but stimulated the erectile reflex. The new alkaloid certainly deserves to be tested in cases of functional impotence, and if the statements made for it are substantiated by further experience, it will supersede the aphrodisiacs now in vogue.

MEDICUS NEO-EBORACENSIS.

DANNEMORA AS A SITE FOR
A STATE SANATORIUM FOR CONSUMPTIVES.

801 MADISON AVENUE, NEW YORK, December 20, 1900.

To the Editor of the *New York Medical Journal*:

SIR: It is a cause for regret to the friends of the anti-tuberculosis movement in the State of New York that difficulty should be encountered in the selection of a site for the first State hospital. One would suppose that certain broad principles underlying the modern sanatorium treatment of this disease had been settled by the experience and discussion of the past fifty years. One would also suppose that these principles were universally applicable, whether the sanatorium were located in England, Germany, or the State of New York. No country in the world, so far as I know, has deliberately selected a site within one or two miles of a State prison and an asylum for insane convicts as admirably suited to the treatment of tuberculosis. New York State is the first civilized community that is considering the advisability of taking such a step in the selection of Dannemora, Clinton county.

It would appear to me that such a step would be inexpedient unless there were absolutely no other place available in the Adirondacks, to which region the trustees are, by law, limited in their choice, or unless the spot selected with this incubus of an insane and convict population presented special climatic or other advantages. The first of these alternative suppositions may be dismissed, because, as a matter of fact, the trustees have inspected more than twenty other sites, any one of which would be possible. A recent visit to Dannemora, an inspection of the site offered at that place, conversation with the prison physician, a study of his plea made in favor of Dannemora at the joint hearing before the State Board of Health and the Forest Preserve Commission, together with a study of the annual reports of the New York Weather Bureau, have convinced me that the second supposition may also be dismissed. A good deal of the medical evidence offered to prove the special advantages for this site has no bearing on the question, and would not appeal to a jury of physicians as entitling it to preference over other places. I refer especially to the pneumonia, typhoid, and tuberculosis statistics. The statistics of the mean temperature and the mean annual rainfall are at variance with the official reports of the weather bureau of the last ten years. The entire plea suggests the ease with which any place may be made to blossom out as a veritable Garden of Eden for the un-

fortunate consumptive, if sufficiently watered and fertilized by local enthusiasm and the imagination of its promoters. In spite of the cheerless and even depressing influence of the Dannemora surroundings as compared with other places in the Adirondacks, nobody will deny that it offers some of the requirements laid down by the trustees for the selection of a site; it has proper elevation, exposure, and water supply. Nor will anybody deny that incipient tuberculosis may be cured at Dannemora—or indeed at any place in the Adirondacks—still, no one would think of erecting a private sanatorium there, and it is the plain duty of the trustees to act for their poorer fellow citizens with the same discriminating judgment.

Let us not be blinded to the fact that the main arguments in favor of Dannemora are the gift of the land and the labor for the construction of the buildings. This is tempting bait; yet it is to be hoped that the trustees will not yield to it. The natural and commendatory desire on the part of the prison officials to secure labor for their convicts should not lead the trustees to subordinate the interests of the consumptive poor to those of the convicts.

This is to be only the second State hospital for incipient consumptives in this country, and upon its success may depend the fortunes of the whole movement in this and other States. Patients are to go there voluntarily, and much, perhaps all, depends upon getting them there early; there ought to be no prejudice in their minds against the place and its associations; no risks should be taken in the choice of site that would entail hesitancy on the part of the patient. Furthermore, be it remembered that the incipient consumptive is not a helpless invalid easily controlled by reason of his very helplessness, but well enough to assert his own individual prejudices.

At some future time, when the movement in this State is itself no longer in the incipient stage, and when the advantages of early sanatorium treatment of consumption have won their way into the hearts of our tenement-house population, the objections against Dannemora may weigh less in the balance, but for the present, at least, Dannemora ought to be eliminated from the list of available sites.

ALFRED MEYER, M. D.

Book Notices.

Cancer of the Uterus. Its Pathology, Symptomatology, Diagnosis, and Treatment. By THOMAS STEPHEN CULLEN, M. B. (Toronto), Associate Professor of Gynæcology in the Johns Hopkins University. With Eleven Lithographic Plates and over Three Hundred Colored and Black Illustrations in the Text, by MAX BRÖDEL and HERMANN BECKER. Pp. xvi-693. New York: D. Appleton & Company, 1900.

THE comprehensive title of this book, published in the same sumptuous style as Kelly's recent work on operative gynæcology, by the same publishers, with the same wealth of beautiful illustrations, and upon a subject in which all the world is deeply interested, raises one's expectations and hopes that now a troublesome riddle is to be solved. But the riddle remains unsolved and we are apparently as far as ever from satisfactory conclusions in regard to that most elusive subject, the ætiology of cancer. This is only saying that the author, like all who have preceded him in his search for the ultimate cause of this scourge of the human race, has been unsuccessful.

Though disappointed that this question still remains open, we are bound to express our satisfaction with the general arrangement and contents of this book. It is

based upon an immense amount of painstaking work, and furnishes a fund of information which probably no other book of its kind has given us. The detailed accounts of many autopsy reports illustrating varied important phases in the pathology of this disease make it a most valuable help to those who are more or less frequently confronted with cancer in its various forms.

The interesting remarks on the anatomy and treatment of the ureters in relation to this disease show the impress of the author's teacher. Work upon these tubes is about as difficult and little likely to succeed, except in the hands of the unusually dexterous, as any variety of work within the abdominal cavity. It is well that this point should be emphasized.

An important part of the work deals with the diagnosis between cancer and other disease. It shows the extreme probability of the existence of cancer among those who had passed the menopause in the presence of certain readily recognizable symptoms, but it also insists upon the utility of the microscope, especially when the primary attack is upon the endometrium. The author would not deny, we think, that an observer of experience could in most cases depend upon the clinical phenomena in making a diagnosis, especially if the disease was limited to the cervix or the cervix and vagina.

The technique of the operative measures for the removal of cancerous tissues offers no new procedures, so far as we have been able to discover, the admonition being to make the removal as thorough as possible, cutting as widely as practicable from the manifestly diseased structures and removing glands which are likely to become infected. The extension to the lymph glands is not so universal as we had supposed, in view of the media by which the cells are transported. This is especially true in cancer of the body of the uterus, and probably explains the superiority of ultimate results after hysterectomy for this variety of the disease. The preference of the author is for abdominal rather than vaginal hysterectomy. This method certainly does permit of the more careful inspection of the tissues and a wider removal than is usually permissible by the vagina.

There is no book with which we are acquainted, certainly no American book, which so beautifully illustrates pictorially the various lesions of tissue which occur with cancer. A careful study of it is almost equivalent to a course in the laboratory and dissecting room, and is not half so laborious, for the specimens are all prepared and displayed to the best possible advantage. We congratulate the author, we congratulate the publishers, and we welcome the book as a praiseworthy contribution to the literature of a most important subject.

A Treatise on Diseases of the Nose and Throat. By ERNEST L. SHURLY, M. D., Vice-President and Professor of Laryngology and Clinical Medicine, Detroit College of Medicine, etc. Illustrated. Pp. xvii-744. New York: D. Appleton & Company, 1900.

THE field of laryngology, with everything usually included under that term, has been pretty thoroughly covered by the various volumes of the last few years, yet the record of a clinician and scientific worker so well and so favorably known as Dr. Shurly cannot but be interesting and profitable. His book has been written "for the perusal of the general practitioner and medical student rather than for the specialist"; hence he has not speculated on unimportant theories or dwelt upon mere historical details, but has endeavored to fairly present both sides of controverted questions.

The general arrangement of the work calls for no spe-

cial comment. The chapters have been written according to a classification based on the general nature of a given disease, rather than according to the anatomical site involved. Thus, we find Tuberculosis of the Upper Air-passages, with subheadings relating to the nose, mouth, palate, pharynx, etc. The volume as a whole is a fair exposition of the science of laryngology as currently taught, especially by American instructors.

Perhaps the chapter on tuberculosis is the one which will be read with greatest interest. While the author is fully abreast of the times on the tuberculosis question and has done much valuable original work along this line, he is not willing to accept without reservation some of the conclusions drawn by certain enthusiastic sanitarians. He has shown his faith by his works, and has had, we understand, one or two differences of opinion with the Michigan State Board of Health. Speaking of the general acceptance of the doctrine of the causation of the disease by the bacillus of Koch, he says that "unfortunately for a strict interpretation of the doctrine, the expected 'tissue reactions' do not always regularly follow upon the evidence of bacillary invasion, nor do the clinical data in many cases confirm either the presence or the operation of the tubercle bacilli." He is inclined to believe "that the rôle of the bacillus in spreading disease has been overestimated and that the independent powers ascribed to it have been also exaggerated." He is also skeptical as to the accuracy of conclusions based on many of the cases of reported contagion from food and milk. These are, however, only isolated statements, and the chapter as a whole evinces a much wider conception of the tuberculosis question on the part of the writer than is possessed by many a rabid critic of the views here expressed. The volume is creditable alike to the author and to the American profession.

Appendicitis and its Surgical Treatment, with a Report of One Hundred and Eighty-five Operated Cases. By HERMAN MYNTER, M. D. (Copenhagen), Professor of Clinical Surgery in the University of Buffalo. Third Revised Edition. Pp. 3 to 231. Philadelphia and London: J. B. Lippincott Company, 1900.

IT is the main object of the author to sum up the weight of evidence for and against the operative treatment for appendicitis. That the opinion of the profession foreign to this country is at variance with the general practice adopted here, is best expressed by quoting from the preface of the writer, in which he states that, while in the United States this disease is considered almost exclusively a surgical lesion, that is by no means the case in other countries. We find there men of undoubted authority, whose opinions are entitled to respect and attention, in the ranks of the conservative physicians, who operate only in exceptional cases and advise against surgical intervention as a standard treatment. He further shows that this conservative line is not warranted by the results obtained, judging from the statistical tables, and concludes that, although radical treatment is not so popular in other countries as it is with us, yet, if their testimony is carefully sifted, it will be found that their mortality is much higher than ours, and consequently it must be admitted that the greatest safeguard to life lies in prompt and energetic treatment, which at once rids the patient of his peril and places him beyond the possibility of a repetition of his troubles. He perhaps will not always find acceptance for the statement that the prevailing custom here is to operate as soon as the diagnosis is established; there are many radical surgeons who frequently find mild cases in which they adopt palliative measures;

not, however, without careful watching and having made preparations for an immediate operation, should it become necessary.

In the opening chapter we find a brief historical sketch which is most interesting and instructive; following in natural sequence, we find chapters on the anatomy, histology, ætiology, pathology, classification, symptomatology, complications and sequelæ, diagnosis, prognosis, and treatment. In the treatment advised we naturally expect to find a strong leaning toward radical measures. The writer ably and succinctly describes the various procedures, practically omitting all details pertaining to operative work in general, the reader being expected to be already conversant with the necessary surgical technique. The monograph closes with statistics of a hundred and eighty-five cases in which the author has been the operator and also personally conducted the after-treatment; these few cases, however, have by no means been the limit of the author's experience, but include only those cases which he has been able to follow to a termination.

This little book is most interesting and attractive, collating as it does many opinions of our most prominent surgeons, and is further enhanced by sound and safe ideas expounded by the author.

Ulceration of the Bladder; Simple, Tuberculous, and Malignant. By E. HURRY FENWICK, F. R. C. S., Surgeon and Pathologist to St. Peter's Hospital for Urinary Diseases, London, etc. Pp. vi-85. London: J. & A. Churchill. Philadelphia: P. Blakiston's Son & Company, 1900. [Price, \$1.75.]

MR. FENWICK'S monograph is a clinical study of a large number of cases of simple, malignant, and tuberculous ulceration of the urinary bladder. The author has laid special stress upon the diagnosis and treatment of these conditions, and, therefore, it is an instructive and interesting work. The author admits that the treatment is not always satisfactory and hopes that with the advance of serotherapy these results may be improved. He utters a warning against promiscuous instrumentation, but insists upon an accurate knowledge of the pathological condition before definite treatment is instituted. As a contribution to genito-urinary surgery, this little book is valuable.

BOOKS, ETC., RECEIVED.

King's American Dispensary. By Harvey Wickes Felton, M. D., Adjunct Professor of Chemistry, Pharmacy, and Toxicology in the Eclectic Medical Institute, Cincinnati, etc., and John Uri Lloyd, Ph. M., Ph. D., Professor of Chemistry, Pharmacy, and Toxicology in the Eclectic Medical Institute, Cincinnati, etc. Entirely Rewritten and Enlarged. Eighteenth Edition. Third Revision. In Two Volumes. Volume II. Pp. viii-905 to 2172. Cincinnati: The Ohio Valley Company, 1900.

An American Text-book of Physiology. Edited by William H. Howell, Ph. D., M. D., Professor of Physiology in the Johns Hopkins University, Baltimore. Second Edition, Revised. Volume II. Muscle and Nerve; Central Nervous System; the Special Senses; Special Muscular Mechanisms; Reproduction. Pp. 11 to 553. Philadelphia and London: W. B. Saunders & Company, 1901. [Price, \$3.00.]

A Clinical Treatise on Fractures. By William Barton Hopkins, M. D., Surgeon to the Pennsylvania Hospital, etc. Pp. 3 to 268. Philadelphia: J. B. Lippincott Company, 1900.

Obstetric Clinic. By Denslow Lewis, Ph. C., M. D., Professor of Gynecology in the Chicago Polyclinic, etc.

A Series of Clinical Lectures on Practical Obstetrics delivered to Students and Practitioners in Cook County Hospital, Chicago, together with Remarks on Criminal Abortion, Infanticide, Illegitimacy, the Restriction of Venereal Diseases, the Regulation of Prostitution, and other Medico-sociologic Subjects. Pp. viii-652. Chicago: E. H. Colegrove, 1900. [Price, \$3.00.]

A Manual of Medicine. Edited by W. H. Allchin, M. D. Lond., F. R. C. P., F. R. S. Ed., Senior Physician and Lecturer on Clinical Medicine, Westminster Hospital, etc. Volume II. General Diseases—Continued. Diseases Caused by Parasites; Diseases Determined by Poisons Introduced into the Body; Primary Perversions of General Nutrition; Diseases of the Blood. Pp. vi-380. New York and London: The Macmillan Company, 1901. [Price, \$2.00.]

The Essentials of Practical Bacteriology. An Elementary Laboratory Book for Students and Practitioners. By H. J. Curtis, B. S. and M. D. Lond., F. R. C. S., Late Surgical Registrar, University College Hospital, etc. Pp. xvi-291. New York and Bombay: Longmans, Green, & Company, 1900.

Experimental Research into the Surgery of the Respiratory System. An Essay awarded the Nicholas Senn Prize by the American Medical Association for 1898. By George W. Crile, A. M., M. D., Ph. D., Professor of Clinical Surgery, Medical Department, Western Reserve University, Cleveland, etc. Second Edition. Pp. 5 to 114. Philadelphia: J. B. Lippincott Company, 1900.

On the Use of Massage and Early Passive Movements in Recent Fractures and other Common Surgical Injuries, and the Treatment of Internal Derangements of the Knee-joint. Three Clinical Lectures delivered at St. George's Hospital. By William H. Bennett, F. R. C. S., Senior Surgeon to St. George's Hospital, London, etc. With Twelve Illustrations. Pp. x-97. New York and Bombay: Longmans, Green, & Company, 1900.

The Present Position of the Treatment of Simple Fractures of the Limbs. An Address delivered in opening a Discussion at the Meeting of the British Medical Association held in Ipswich, August, 1900. By William H. Bennett, F. R. C. S., Senior Surgeon to St. George's Hospital, London, etc. To which is Appended a Summary of the Opinions and Practice of about 300 Surgeons. Pp. 41. New York and Bombay: Longmans, Green, & Company, 1900.

On Some Cirrhoses of the Liver. Being the Lumleian Lectures for the Year 1900, delivered before the Royal College of Physicians, London. By Walter Butler Cheadle, M. A., M. D. Cantab., Senior Physician and Lecturer on Clinical Medicine, St. Mary's Hospital, London, etc. With Illustrations. Pp. 109. London: Smith, Elder, & Company, 1900.

Transactions of the American Gynecological Society. Volume XXV. For the Year 1900.

Medical and Surgical Reports of the Boston City Hospital. Eleventh Series. Acute Yellow Atrophy of the Liver. By Stephen Smith Burt, M. D. (Reprinted from the *Lancet*.)

The True Suspended Position. By George J. Engelmann, M. D., of Boston. (Reprinted from the *Transactions of the Third International Congress of Gynecology and Obstetrics*.)

Treatment of Typhoid Fever. By Stephen Smith Burt, M. D. (Reprinted from the *Medical News*.)

Diagnosis of Diseases of the Stomach. By Charles D. Aaron, M. D., of Detroit. (Reprinted from the *Medical Standard*.)

Miscellany.

Foreign University News.—In the University of Kieff 150 candidates appeared at the examination for the license to practise. The government commission rejected five of these applicants. Twenty-two received the license with honors, and the title "Woman Physician" was granted to two women, one a graduate of the University of Berne, the other of the University of Paris.—Graduates of foreign universities are entitled at present to admission to the examination for the title of "Physician" which is held periodically in the Russian universities. The diploma obtained after passing this examination entitles the holder to practise medicine throughout the empire. Heretofore foreigners were allowed to take this examination in Latin or in one of the modern languages, and they were admitted to the examination without presenting the "certificate of maturity," which represents a collegiate education. On the other hand Russian subjects were obliged to take the examination in Russian for a certificate of graduation from a "gymnasium" of recognized standing, in addition to certificates testifying to their attendance upon medical courses for a period of five years.—In 1900 there were 148 applicants for the title of "Physician" at the University of Charkoff, a degree lower than that of Doctor of Medicine but entitling the holder to practise in Russia. This title is the regular credential of the average Russian practitioner; only those who are specially gifted or who intend to enter State service or an academic career, usually apply for the degree of M. D., which is obtained on passing a special examination and on successfully defending a dissertation which must embody original research. As a rule this takes two or three years after graduation from the regular medical course. Of these candidates not one was rejected, twenty-seven received honors, and three were women.—The number of applicants for the title of "Physician" at the University of Kasan was 114, of whom six failed at the examination, fifty were awarded honors, and eleven were women.—The number of students in the first year of the medical course which was opened at the University of Odessa this year is 125.—The Austrian Minister of Public Instruction has issued an order according to which there will be triennial increase in the salaries of assistants, prosectors, etc., in the universities until the ninth year of service has been reached. From that time on, the salary will remain fixed, unless the recipient is promoted. This order will go into effect on October 1, 1901, and its execution will materially assist in improving the condition of those of the lower grades in the academic service, who have been heretofore proverbially underpaid.—Professor Kossel, of Marburg, has been called to the chair of physiology at the University of Heidelberg in place of the late Professor Kuehne.—Professor R. Paltauf has been appointed to the vacant chair of general and experimental pathology at the University of Vienna, and has given up the chair of bacteriology.—The competition for the chair of obstetrics and gynecology which was announced some time ago at the University of Kieff, brought applications from eighteen candidates, of whom three were rejected as not satisfying the conditions of the competition. The remaining fifteen candidates presented a total of 472 works to the appointing commission. The three candidates whose names will be submitted to the Minister of Public Instruction for appointment are Professor Grammatikati, Professor Muratoff, and Dr. Massen.—The antagonism against classics has expressed itself rather vigorously in the recent promulgation of the

requirements for entrance to the medical school for women in St. Petersburg (The Imperial Medical Institute for Women). Beginning with next year, the students will only be required to be able to translate easy Latin authors like Cæsar and Sallust, and the examination will be oral. The Minister of Public Instruction in Russia has appointed a commission to investigate the advisability of admitting to the university faculties of medicine and natural sciences candidates who are graduates of scientific schools (Real-gymnasia). The solution of this question is of great importance to hundreds of young men throughout the empire.

The Medical College of Cornell University.—While the new building of the Medical College of Cornell University on First Avenue between Twenty-seventh and Twenty-eighth Streets, has been in use for some time, it was formally opened on Saturday evening, December 29th. Professor Schurman, president of Cornell University, presided over the exercises, which were held in the main lecture room of the building. Seated with the president were Mr. Seth Low, president of Columbia University, Governor Roosevelt, Dr. Wm. M. Polk, dean of the college; and Dr. Lewis Atterbury Stimson, professor of surgery in the institution.

In his opening address President Schurman said that never before in the history of the world had such a gift been made for medical research as that which made possible the erection and maintenance of the new Medical College of Cornell University, and that the generosity of the donor, Colonel Oliver H. Payne, and his high aim in making the donation, imposed very grave responsibilities upon the college authorities. Dr. Stimson in his address spoke of the philanthropic work done by Colonel Oliver H. Payne. He said that the building of the medical college was only one of a series of gifts made by Colonel Payne in the interests of medical science. Dr. Stimson also outlined the system of teaching in the college, and spoke of the opportunity afforded for research by the erection of the building and the endowment of it. He also referred to the course of instruction in the medical schools a century ago and outlined the steps taken for the development of medical science and medical instruction since then.

Governor Roosevelt followed Dr. Stimson, and devoted the major portion of his remarks to the obligations imposed by riches, citing the munificence of Colonel Payne, which made the erection of the new college building possible, as a striking instance of a proper appreciation and fulfilment of the obligations imposed by the possession of riches.

President Low spoke briefly, as did Dr. Polk, the dean of the faculty. Dr. Polk was in charge of the reception. He was assisted by all the other members of the faculty, together with a number of other physicians. The committee of the faculty having the reception immediately in charge was composed of Dr. James Ewing, Dr. Irving S. Haynes, Dr. W. Gilman Thompson and Dr. F. W. Gwyer.

The structure, which cost with equipment about \$750,000, is located on First Avenue between Twenty-seventh and Twenty-eighth Streets, opposite Bellevue Hospital. In architecture, the building follows a severe style of Renaissance. Indiana limestone and red brick are the principal materials used in its construction.

The interior of the building represents the latest stage of equipment for medical purposes, including a cold storage plant, incineratory furnace, operating theatres, Röntgen-ray laboratories, chemical, bacteriological and medi-

cal laboratories, amphitheatres, dispensary and dissecting rooms, class rooms, libraries and offices, all of which are models of excellence in design and equipment. The building itself is fireproof throughout, brick, marble, tile and steel being components. Even the trim of the doors is iron, treated with enamel paint, and disinfection of the entire building is comparatively simple. In connection with the college building proper, the Loomis laboratory will be employed as a place for the study of materia medica, therapeutics and pharmacology, both in museum and work room. The gift of Colonel Payne includes a munificent endowment fund, the income from which is applied to the general expenses of conducting the institution.

Wisconsin's Proposed New Marriage Law.—A marriage law is to be presented at the next session of the Wisconsin legislature, which is attracting attention. The bill provides, among other things, that a board of medical examiners be formed and maintained by the State. No license to marry shall be issued to persons contemplating marriage unless they shall have received from the board a certificate setting forth that they are free from insanity, consumption and tainted blood.

Research Work in Mental Pathology.—At a meeting of the New York Neurological Society, held on January 1st, the following report was read and unanimously adopted:

"The Committee of the New York Neurological Society, appointed at the request of the president of the New York Commission in Lunacy, to offer suggestions as to a scheme of scientific study of mental diseases in connection with the State's hospitals for the insane, begs leave to report as follows:

"1. It is to the interests of the State that original research work should be carried on in relation to insanity, in order that the science should be advanced and better methods of prevention, treatment, and cure discovered. This is of direct interest to the taxpayer, upon whom falls the burden of the care of the insane.

"2. There should be one central laboratory in the State, wherein the energies of the best scientific men in the various departments of medicine related to insanity should be devoted wholly and exclusively to the prosecution of original research.

"3. Such a laboratory, combining the labors of well-qualified workers in general pathology, neuropathology, psychology, chemistry, anthropology, and other requisite branches, should be able to produce from year to year results which would be creditable to the State as a patron of science, as well as invaluable in advancing the knowledge of the methods of treatment and cure of mental disorders.

"4. Each hospital for the insane should have upon its staff of medical officers one physician whose sole duty it should be to conduct ordinary autopsies and to carry on the routine duties of a clinicopathological microscopist.

"5. The central laboratory, or pathological institute, should be freely open to any qualified scientific men for the prosecution of original research work, under the direction of the laboratory experts, preference always being given to the qualified men in the State hospitals. But systematic teaching of fundamental principles should not be required from any of the departments of the laboratory. The scientific men in charge of the various departments of the pathological institute should devote all their energies to original investigation, and not be taxed, hampered, or interfered with by medical men who are

able to obtain instruction in fundamental principles elsewhere without cost to the State.

"6. The central laboratory for original research should be a part of a reception hospital for the insane situated on Manhattan Island."

The Late Dr. J. Henry Fruitnight.—The following preambles and resolutions were recently passed by the Northwestern Medical and Surgical Society:

Whereas, It has pleased Divine Providence to sever by death the membership of Dr. J. Henry Fruitnight in the Northwestern Medical and Surgical Society, a membership lasting nearly a quarter of a century; and,

Whereas, We, the members of this society, desire to place on record our appreciation of the noble and self-sacrificing character of our late colleague, sadly cut down in the prime of life; therefore be it

Resolved, That in the death of Dr. Fruitnight this society has lost a modest and congenial companion, a true friend, and a valued professional colleague, whose earnestness of purpose and unselfishness of motive peculiarly fitted him for a large and useful medical career; that he is a severe loss to this society, in which he took a warm personal interest, to the many other medical bodies of which he was a member, and also to the medical profession and the entire community; that his published writings, concise discussions, and discriminating thought are worthy of our highest regard.

Resolved, That we sincerely extend our heartfelt sympathy to the members of his bereaved family, wishing for them that consolation which the memory of such a noble life alone can give.

Resolved, That a copy of these resolutions be spread upon the minutes of this society; that duplicates be sent to the *Medical Record*, the *New York Medical Journal*, the *Medical News*, the *Archives of Pædiatrics*, and *Pædiatrics*; and that an engrossed copy be prepared for the family of the deceased.

For the Northwestern Medical and Surgical Society,

A. E. BIESER,

Committee.

To the Members of the American Medical Association: Your attention is called to the fact that there is at present pending in Congress certain proposed legislation that seriously disturbs the present status and efficiency of the medical corps of the United States Army.

The proposed law is entitled An Act to Increase the Efficiency of the Military Establishment of the United States (Senate bill 4300) and in a general way modifies the existing organization of the army, while at the same time it provides for a damaging and offensively invidious discrimination against the medical corps. This fact is shown in the following particulars, viz:

1. It decreases the percentage of composition of the corps in the grades of colonel from 3.1 per cent. to 2.4 per cent.

2. It decreases the percentage composition of the corps in the grade of lieutenant-colonel from 5.2 to 5.7 per cent.

3. It decreases the percentage composition of the corps in the grade of major from 26 per cent. to 18.6 per cent.

4. It *increases* the percentage composition of the corps in the grade of assistant surgeon with the ranks of captain and first lieutenant from 65 per cent. to 74.7 per cent.

The significance of these proposed changes can be understood when it is remembered that, even under the existing law, it requires more than eighteen years to reach the grade of surgeon with the rank of major, while under the proposed law it will require at least twenty-five years to reach the same grade and rank. With this fact reduced to a mathematical demonstration, the inevitable result will be, first, that the more worthy young men will not apply for commissions, and, secondly, that the relatively less worthy men who do enter the service, discouraged by the certain impossibility of reasonably prompt promotion, will resign, leaving their places to be filled by untrained and consequently less efficient men. The ultimate disaster from this contemplated change, however, will consist, not alone in a lowered status of the medical service, but (1) in increased disease and death rate among the men, (2) in a diminished and otherwise weakened force on the firing line, and (3) in a material augmentation of the pension roll.

In view of the foregoing facts, and in view of the fact that every other corps of the army is better graded than is the medical, every member of the American Medical Association and every member of the medical profession is hereby earnestly solicited to send at once to his United States senator and congressman an urgent and emphatic protest against the proposed provisions in Senate bill 4300 relative to the medical corps of the United States Army.

[Signed] CHARLES A. L. REED,

President of the American Medical Association.

CINCINNATI, O., December 29, 1900.

Out-of-School Work Forbidden in Russia.—In a recent circular dealing with the reform of secondary education in Russia, the minister of public instruction ordered that the custom of giving the scholars work to be done during the summer vacation be abolished, and that a series of instructive summer excursions and voyages be organized for the scholars under the supervision of competent teachers.

The Death Rate from Contagious Diseases in St. Petersburg has been on the increase for the past six or seven years, thus placing the Russian capital in marked contrast with the other large cities of Europe and America. Thus in the year 1891, 2,489 persons died in St. Petersburg of typhoid, typhus, small-pox, diphtheria, or scarlatina; in 1893 and 1894 about 3,000. In 1896 and 1897 over 3,000, and in 1900 the mortality from tuberculosis shows a similar increase. The number of deaths ranging from 3,500 to 4,000. These facts do not speak well for the administration of the Russian capital.

Mosquito Inoculation Successful.—General Sternberg recently received from Dr. Walter Read, of the Medical Department, the results of the experiments with mosquito inoculation. The experiments have been entirely successful in eighty per cent. of the cases under treatment. These experiments were conducted by Dr. Read and other surgeons in Havana. So far the inoculation has been successful in all the migrants intending to settle in the United States.

have voluntarily presented themselves for inoculation with a full understanding of the nature of the experiment.

University Medical College Addition.—The University Medical College of Kansas City has recently completed its additions, which practically double the capacity of the school. A feature of the new college is its amphitheatre for surgical clinics, which combines the best features of Eastern institutions. A chemical laboratory occupies the third floor, and on the fourth floor are located the pathological and bacteriological laboratories. In the basement are eleven clinic rooms. The entire fifth floor is used as a dissecting room. The building, with its finishings and equipment, represents an expenditure of \$35,000.

Library for Rush Medical College.—Four thousand volumes of medical and surgical writings have been presented to the library of Rush Medical College, Chicago, by Dr. Christian Fenger. Comprised in the gift is a practically complete collection of theses presented for the degree of doctor of medicine at German universities, which embody in a sense the entire history of surgery for the last fifty years. This part of the gift is looked upon as almost priceless, because it is rare that an opportunity to obtain a duplicate occurs. The collection was originally made by Thiersch.

Foreign Hospitals, etc.—The administration of the city hospital of Odessa has handed in an estimate for the maintenance of this institution for 1901 to the city government. They ask about 470,000 roubles, or 50,000 more than last year. These figures are interesting when compared to the budgets of other city hospitals in Russia. According to the *Archiv Pathology*, etc., for October, 1900, Odessa spends one-tenth of its city revenue for the maintenance of its medical institutions—more than any other Russian city. The mortality of Odessa, on the other hand, is lower than that of St. Petersburg or Moscow. In 1900, Odessa spent 1,083,175 roubles for its hospitals, charities, and sanitary administration, while the whole city revenue for that year was only 5,239,350 roubles.—The city administration of St. Petersburg has decided to establish in that city twelve dispensaries for the outdoor poor in buildings belonging to the municipality. The sum of 90,000 roubles has been apportioned for the support of these institutions for the coming year. In addition to the regular day service, there will be also a night emergency service with a physician on duty at each of these dispensaries. Physicians in private practice will be appointed to these positions, and will be paid for each visit made during the night.—Eleven hospitals which are supported by the municipality of Moscow cost that city 1,487,400 roubles during the year 1900.—Professor Hochenegg has been appointed director of the surgical clinic of the late Professor Albert in Vienna. Professor Hochenegg directed this clinic in 1896, during Albert's sickness.

Colleges Recognized by the Michigan Board.—At a recent meeting of the Michigan board of registration in medicine, the following five colleges were added to the list of those recognized by the board as being colleges of good standing: Western Reserve College, Cleveland; University of Buffalo, Buffalo, N. Y.; Albany (N. Y.) Medical College; women's department of the Northwestern University, Chicago; Illinois Medical College, Chicago, and Hahnemann Medical College, Philadelphia. This makes a total of forty-two colleges the diplomas of which are recognized by the Michigan board.

A PECULIAR CASE OF
MIGRATORY FOREIGN BODY,
WITH X-RAY ILLUSTRATIONS.*

By D. BRADEN KYLE, M. D.,

PHILADELPHIA.

I DESIRE to report this case of migrating foreign body in the face on account of its unusual interest and the complicated and varied symptoms which were present.

While the marked symptom in each attack was the frightful neuralgic pain, yet the change in the site of the pain, soreness, and swelling was the misleading factor. At times one would almost suspect mastoiditis, again facial neuralgia, again ethmoiditis, and, lastly, all the symptoms of confined suppuration of the maxillary sinus. Yet when the attack was over and the acute inflammatory symptoms had subsided, there was such an absence of any symptoms that it was impossible to locate any special diseased area.

An interesting feature of the case was the x-ray burn which resulted in our endeavors to locate the foreign body. Twenty-four hours after the x-ray picture had been taken an acute dermatitis developed on the right side of the face. The hair came out in handfuls extending almost to the median line. Later on the skin blistered and peeled off. There was no bad effect systemically from this burn, and to-day, curiously enough, the portion of the head on which the burn extended is covered with hair again, although it is short, being only two or three inches in length.

The history of the case, as given by the patient and the physician in attendance, is as follows: The first attack occurred in the latter part of January, 1887, and lasted for nine weeks. The beginning of the attack was rather curious. There was a sensation of something crawling, not on the scalp but underneath, that seemed to extend from the back of the neck forward over the top of the head. This was followed by considerable swelling and severe pain. The attack continued for nine weeks, and sometimes from the pain and extreme swelling the patient would become almost comatose. During this time the patient gave birth to a month's fœtus.

The symptoms gradually lessened after about nine weeks, until they would almost entirely disappear, but for three years, or until 1890, the patient would have repeated attacks, although not quite so severe as the attacks which occurred in 1887. The swelling, which was at first largely in the back of the head, with each attack traveled farther forward, and the tenderness and swelling over the mastoid region were quite pronounced. During all this time the patient, who was considered hysterical, described the sensation as that of something crawling underneath the scalp, and insisted that on each attack that peculiar sensation extended farther forward. In 1890 another severe attack occurred in which the swelling and tenderness over the mastoid were so pronounced that a diagnosis of acute mastoiditis was made. The patient refused an operation at that time. In a few

days the symptoms gradually abated until all the swelling and tenderness disappeared. From 1890 to 1895 no severe attacks occurred, but there was continually present that peculiar crawling sensation. Another curious symptom was this: Frequently, and especially when the peculiar crawling sensation was aggravated, there was a profuse sweating from the scalp and the skin of the face, which did not occur in any other part of the body. This was a peculiar pasty, sticky material. The same material was discharged from each ear.

In December, 1898, an acute attack occurred. The peculiar sensation of which the patient had complained all these years had finally reached the forehead. The attack which occurred in December, from the symptoms given by the patient and the physician, was almost identical with the confined suppuration of the frontal sinus.

FIG. 1.

There was considerable external swelling, besides the dull, boring pain which is almost characteristic of a confined suppuration. Without any surgical interference there was a profuse discharge of pus from the nostrils, which gave almost immediate relief to the patient. Shortly after the first discharge of pus the patient, in freeing the nostril by rather forcible blowing, felt some hard substance in her handkerchief. On examination, she found a small piece of needle, about one half of a needle, as it afterward proved. In a few days the discharge cleared up, and the patient was free from any discomfort. The portion of needle which was discharged at that time, unfortunately, the patient did not keep, but the doctor and three members of the family who saw the piece of needle all agreed in their statement as to the size and discoloration of the needle. The surface of the needle was not roughened, but was simply oxidized. After the discharge of this portion of the needle the peculiar crawling sensation ceased.

*Read before the American Laryngological Association at its twenty-second annual congress.

When I first saw the patient, on August 23, 1899, there was a pronounced swelling on the right side of the face, reaching the antrum and up into the orbit, and at the base of the nose. There was marked tenderness on pressure, and the patient suffered severe pain, the pain at times being so severe that opiates had to be administered. At the time she was under the care of Dr. Lawrence Simcox, of Wissahickon. He had attended her through several previous attacks. There was considerable discharge from the nostril, although it was nothing more than would have followed a severe cold. Examination of the nasal cavities revealed nothing. Transillumination of the accessory cavities also gave negative results. I therefore hesitated to use any surgical interference on account of the previous history, similar swellings having occurred elsewhere about the face and head. This attack subsided and the patient was fairly free from

of the antrum, or even outside of the antrum. The exploratory opening was made into the antrum and the whole antral surface explored, not only with the probe, but with the electric magnet. Dr. William M. Sweet, who has had great success in the removal of foreign bodies from the eye with the Hirshberg magnet, was present and used the instrument. Once or twice he was positive that the instrument was attracted to some metallic substance, but he was unable to locate it. As we could find nothing in the antrum, and did not know the positive location of the foreign body, we decided to do no further cutting, but, if possible, to locate with the x-ray the exact position of the needle, which we now believed to be there. A few days after the operation there appeared, just about a quarter of an inch back of the opening which I had made into the antrum, which was in the canine fossa, a swelling which looked much like an ordinary

FIG. 2.

pain for some three weeks, when another attack as severe as the former occurred. It was then that, while I did not attach much importance to the history of the discharge of the piece of needle, as a last resort it occurred to me that possibly there was a foreign body somewhere in the cranial cavity that was setting up this curious chain of symptoms. The patient consented to have an x-ray picture taken. It was with considerable difficulty that we seemed to outline the foreign body, the picture which I present being the best of a number taken. However, we felt satisfied that there was a foreign body present. The second x-ray picture showed a slight difference in its location, as is shown in the photograph.

Granting that the x-ray picture was true, we decided to explore the antrum. It was impossible to determine whether this black line shown by the x-ray picture, which we believed to be the foreign body, or needle, was within the antrum or in the bony posterior wall, or anterior wall

FIG. 3.

gum boil. This continued for a day or two, when it opened and, on examination by the patient's husband, at the suggestion of the patient that the boil had ruptured and that there was something causing considerable pain, he discovered projecting from the tissue the point of this needle. Catching it with a pair of ordinary scissors he withdrew the body, and here it is.

The patient made a rapid recovery, and since that time has had no return of the symptoms, and is in perfect health to-day.

How the needle entered nobody knows. What course it pursued we cannot tell, but it is reasonable to suppose that the chain of symptoms was produced by the moving body. I have made a careful search of the literature and I do not find any similar case reported. We all meet with curious and unexplainable cases, and I have reported

this case hoping that possibly it might be a help to some of us from a standpoint of diagnosis, as I frankly confess it was a most puzzling case to me, and it was with little faith that I started in search for that portion of the needle.

The x-ray prints are not so clear as they should be, or so clear as is shown on the negative. The case also shows the value of the x-ray as a diagnostic aid.

TWO CASES OF HÆMARTHROSIS OF THE KNEES.

By RUSSELL A. HIBBS, M. D.,

NEW YORK.

THESE two cases were shown at the meeting of the Orthopædic Section of the Academy of Medicine, April 20, 1900. The patients are brothers, aged respectively eleven and fifteen, and were first seen by me at the New York Orthopædic Dispensary, July, 1899. There was at this time a distinct effusion in the knees of both, and some tenderness and slight thickening of the synovial membrane, with such limitation of motion as would be produced by the effusion, viz., the extremes of flexion and extension, but no reflex muscular spasm. They were practically in the same condition when shown at the Academy.

The father died of some acute illness, the mother is healthy. Two hæmophilic brothers died in infancy, and one sister is alive and well.

These attacks have been recurring at frequent intervals

FIG. 1.

for several years, leaving the joints so painful that walking is difficult or impossible for a few days afterward, and

sufficient time had not elapsed between the attacks for the effusion to entirely disappear. Thus, there is a constant condition of chronic synovitis. Elastic knee caps were

FIG. 2.

advised and afforded some relief. In the case of the elder, however, the attacks have become more frequent and the disability so marked that it has been necessary to apply a support to more fully protect the joint. In the younger they are becoming less frequent and no other treatment has been required.

It is evident from the histories that these attacks of synovitis are due to hæmorrhage into the joints, and that they illustrate a comparatively rare form of joint lesion.

No other joint has been involved and these attacks are not always accompanied by other hæmorrhages.

Photographs Nos. 1 and 2, of the elder and younger respectively, show the joints as they appeared when first seen. Radiographs do not show evidence of bony change.

REPORT OF TWO CASES OF DERMOID CYST OF THE NOSE.*

By H. S. BIRKETT, M. D.,

MONTREAL.

PROFESSOR OF LARYNGOLOGY, MCGILL UNIVERSITY; LARYNGOLOGIST TO
THE ROYAL VICTORIA HOSPITAL.

THE comparative rarity of the occurrence of dermoid cysts of the nose and the interest attached to tumors of this nature are my excuse for adding two more cases to the literature on this subject.

*Read before the American Laryngological Association at its twenty-second annual congress.

The first case, for which I am indebted to Dr. Cornell, of Brockville, Ont., concerns a young man, sixteen years of age, who consulted me three years ago on account of a "discharging sore" situated near the tip of the nose, in the middle line.

His father gave the following history concerning his son: At birth it was noticed that there was a small round

FIG. 1.

lump, of about the size of a large pea, on the nose near the tip. This remained so, unaltered in size and shape, until August, 1896, when it burst and gave exit to a small quantity of thick, curdy-looking pus. The opening was enlarged and the lesion curetted elsewhere. The resulting wound soon closed and remained so for several weeks, when the lump made its reappearance and broke, and has continued to discharge ever since. Upon examination, there is noticed a small opening, circular in shape and about two millimetres wide, situated in the middle line of the nose and about five millimetres from the tip. A skiagram was made of the nose, with the object of ascertaining whether a sinus existed, as it seemed impossible to find it with a probe. The result was that the skiagram showed a fine dark line, leading from the centre of the opening directly upward and backward into the septum. The result of the skiagraphy is shown in the accompanying picture (Fig. 1, X). After a good deal of difficulty, a very fine probe was successfully passed into the sinus and took a direction as indicated in the skiagram (X). The sinus was opened and freely and thoroughly curetted, and solid nitrate of silver applied. The sinus itself was found to be lined with a dense fibrous membrane, with sebaceous material covering its surface. At the distal end of the sinus and within it, several fine hairs were found close to the opening. The wound thus made was allowed to heal up thoroughly from the bottom, leaving a very wide cicatrix which is seen

upon close examination of Fig. 2. This was subsequently dissected out, and the edges were freshened and united. The result, which was extremely satisfactory, is shown in Fig. 3.

The second case, for the history of which I am indebted to my house surgeon, Dr. R. J. Tooke, concerns a young boy, aged eight years, who, according to his parents' statements, has had a growth on his nose since birth, which, though small at the time, has recently slowly increased until reaching its present size. Upon examination, a tumor, somewhat oval in shape, is noticed occupying the greater portion of the bridge of the nose. It extends from one-fourth of an inch above a line drawn horizontally from the eyebrow on the one side to that of the other, and continues downward for an inch, reaching to about the centre of the nose. At the upper portion it is broader and gradually narrows below, assuming thus somewhat of a pear-shape, and at the lower point a few fine hairs are noticed. In length it measures an inch and a quarter, and in breadth, at the widest part, half an inch (see accompanying Figs. 4, 5, 6). These photographs show remarkably well the disposition of the tumor and its shape. The tumor is soft in consistence, semi-fluctuating, and has very limited movement over the underlying structures.

A skiagram shows no deep involvement and no separation of the nasal bones. As a result of the exposure to the X-rays, the tumor next day showed a slight diffuse redness, and distinct fluctuation was to be felt. The skin covering the cyst was incised vertically in the middle line from base to apex, and the wall carefully dissected out. The wound was closed in its entirety by horse-hair sutures, except a very small part of the lower end of the incision, which was left open, and into this a small gauze drain was inserted. The object of this was that, in case of any discharge setting in, it should freely drain away without interfering with the primary union of the upper portion of the incision. This proved beneficial, as there was a slight purulent discharge for a few days, which gradually diminished, and in the course of three weeks the opening had completely closed, leaving a very imperceptible scar. The result is seen in the accompanying photographs, Figs. 7 and 8.

The pathological report from the laboratory of the hospital is as follows: "Soft contents of a homogeneous-

FIG. 4.

FIG. 5.

FIG. 6.

looking caseous material resembling mortar, microscopically of cellular debris, flat crystals, and fine, pale hairs. Cyst wall is largely of unstriped muscle, but contains a small amount of fibrous tissue and fat, with blood-vessels. Some free hæmorrhage."

Sutton makes the following remarks regarding the

development of the nose in connection with dermoid cysts: "In the early embryo the rudiment of the nose is

The rounded angles of the frontonasal plate are known as the globular processes. Each process forms a portion of

FIG. 2.

FIG. 3.

represented by that process of the primitive skull known as the frontonasal plate, and this is separated from the lateral portions of the face by the orbitonasal fissures.

the ala of a nostril and the corresponding præmaxilla. These processes fuse in the middle line and give rise to the central median piece (philtrum) of the upper lip.

FIG. 7.

FIG. 8.

These dermoids are invariably situated in the line of the internasal fissure, and are in all probability due to incomplete fusion of the globular processes."

From old and recent literature which has been consulted, I have been able to find only six similar cases in addition to those under consideration. Ligorio (2) reports one; Lawrence (3) two; Bramann (4) three. There are many recorded cases of dermoid recesses, but only the above-mentioned cases were instances of distinct tumors.

Stewart (5) reports a case of deformity of the nose which, from the history given, had its origin in a dermoid cyst, but its nature at the time of the first operation was not recognized.

Note.—Since writing the foregoing, I have had the good fortune to see a third case of dermoid cyst of the nose. This concerns a female child, nine months of age, who at birth presented a definite tumor of about the size of a small pea, situated in the middle line and near its tip. Owing to the parents' leaving at once for the seaside, it was impossible to get a photograph taken in time or to perform any operation, but this will be done on the child's return to town this fall.

THE METHOD OF EXAMINATION OF INFANTS.

By C. HERRMAN, M. D.,

NEW YORK.

THE examination of infants differs in many respects from that of older children and the adult. In the following paper I shall confine myself to these points of difference.

During the examination, two things must be borne in mind, in order that undue weight should not be laid on seemingly abnormal conditions.

1. What is normal to the infant as against older children and the adult?

2. Are there any abnormalities in the particular infant under examination which are not due to the present illness? If such are present, they may be either congenital peculiarities or the result of previous disease.

As an illustration of the value of a knowledge of such a congenital peculiarity, I shall cite a case which Professor Filatow mentions as occurring in his own family. A child of two years was attacked with diphtheria. As soon as the diagnosis was made, the other children were isolated. However, on the very first day the examination of the throat of one of these children showed the presence of

an irregular grayish-yellow spot on the right pillar of the fauces. This was incorrectly assumed to be a diphtheritic patch. Later, a true membrane appeared, and the first proved to be a congenital peculiarity. I have recently seen a similar spot in a patient who had absolutely no throat trouble.

How is such a knowledge of the infant to be obtained? If one child in a family has, let us say, some throat affection, it will be not only justifiable, but desirable, to examine the throats of the others. If the child has some local affection, the other organs which are probably not involved may be examined. In this way, the personal error, as it were, of that particular patient may be determined. It is just in this respect that the family physician has the advantage over the consultant. The latter may have a greater general knowledge, but the family physician is better acquainted with the peculiarities and idiosyncrasies of that particular patient.

In order to have a permanent record of the size of various organs or of the position of murmurs or lesions, they may be marked with an aniline pencil upon the skin, and then traced through linen prepared for this purpose. Paper stamped with the outline of the body and ribs may also be used. These graphic records will be valuable for future comparison.

In general, the physical examination of the infant is more difficult than that of older children and adults, on account of the lack of voluntary cooperation on the part of the patient. For this reason, and also in cases in which the examination is extremely painful, the administration of chloroform may be necessary.

The interpretation of the results of the examination, however, is simpler. One organ only is usually primarily affected, and that acutely. There are no misleading statements with regard to subjective symptoms.

Peculiarities to be remembered are the tendency to collapse in weak or atrophic infants, the sudden fall in temperature, said to be due to a paralysis of the heat-producing centre, the sudden rise in temperature due to paralysis of the heat-regulating centre, and the tendency to convulsions due to the diminished activity of the inhibitory centres with a normal irritability of the peripheral nerves.

If the examination of different parts is here taken up in regular order, it is only for convenience. In practice, this is not always possible. Advantage must be taken of favorable moments for the examination of certain organs. As a general rule, those parts of the examination which are the most unpleasant for the child should be performed last (*e. g.*, the throat).

A complete examination will not always be made. Lack of time or inclination will interfere. As the infant usually falls asleep after being fed, in families in which this is done at regular intervals, the visit may be so timed that the patient can be observed in sleep. This is a great advantage. It is only at such a time that the frequency of the respiration and pulse or even the height

of the temperature can be accurately determined, for all these are increased by the fear and struggling of the infant. This is a favorable time, also, for observing the position of the body, whether the patient lies quietly, on the back, or on the side. The position of the head, arms, hands, legs, the expression of the face, and movements, if any, of the mouth and lips, are also noted.

A sufficient amount of information will be obtained from the mother with regard to hereditary influences, previous pregnancies, her condition during the last pregnancy, the birth of the infant, its age, previous condition, how fed, when the first tooth appeared, and when it began to walk; also as to the possible cause of the present trouble, when and how it began and what symptoms she has noticed since. An intelligent mother will often observe slight changes unperceived by the physician. When resting, moreover, the child is so dressed that the covering may be easily removed. If possible, it should be brought to the window, facing the light.

Physical Characteristics.—As the tables of the size and weight of normal infants given by different authors differ greatly, and as it is often impossible to refer to such a table, the figures most easily remembered are the best for practical purposes. If the length at birth is taken as 20 inches, during the first year there is an increase of 8 inches. During the second year, an increase of half as much, or 4 inches.

At Birth.	1st yr.	2d yr.
20" +	8" = 28" + 4" = 32"	
At Birth.	1st yr.	2d yr.
7 lbs.	+ 12 =	19 + 6 = 25

If the weight at birth is taken at 7 pounds, during the first year there is an average increase of 1 pound a month. During the second year of half as much, or half a pound a month. The head is relatively large and the circumference (fronto-occipital) greater than that of the chest at the level of the nipples.

Circum.	At Birth.	7th mo.	21st mo.
Head.	33 to 35 ctm.	44 ctm.	47.5 ctm.
Chest.	31 to 33 "	43 "	47 "

The general development and state of nutrition, best ascertained by palpating the inside of the thigh and the gluteal region, are noted. Also the general appearance, the color of the skin, whether pale, cyanotic, icteric, œdematous. On the head, the size of the skull, its form, soft spots, if any; the size of the anterior fontanelle (open until the eighteenth month), whether it is prominent or depressed. Auscultation of the fontanelle gives, normally, from the sixth month, a systolic murmur synchronous with the systole of the heart. It is usually more distinct in anæmic and rachitic infants, and often disappears when fluid accumulates in the cranial cavity.

The eyes, ears, nose, and lips may be next inspected, also the size of the neck. The thyroid gland, the large vessels of the neck, the cervical and submaxillary glands,

and the sternocleidomastoid muscle should be palpated. Then follow the examination of the chest, abdomen, extremities and genitals.

Temperature.—It is hardly necessary to dwell on the importance of taking the temperature in all cases in which an acute infectious disease is suspected, more especially as in the exanthemata the characteristic eruption does not appear for some hours. The hand placed on the surface of the body is not reliable, as it is possible to have a normal external with a high internal temperature.

The temperature should always be taken in the rectum, for this requires less time (from one and a half to two minutes), is more accurate, and is not painful. The infant lies on its side in the mother's lap. She steadies the pelvis. The bulb, covered with a little vaseline, is introduced about one inch with a rotary motion, so as not to catch in the folds of mucous membrane. It is well to be prepared for a movement of the bowels. The daily maximum and minimum must be taken into account. Anything below 100° F. in the rectum is normal in infants up to the end of the second year.

Some infants are subject to a pretty marked increase of temperature from comparatively slight causes (indigestion, cold, psychical causes). I have noticed this oftener in rachitis and in the scrofulous diathesis.

We are taught that, in measles, for example, a high temperature after the eruption has begun to disappear, indicates the probable existence of some complication. Still, many such cases will show no complication, but will run a perfectly normal course.

The range of temperature is much greater than in the adult. As low as 77° F. in sclerema neonatorum, and as high as 108° F. just before death in tuberculous meningitis.

Owing to the tendency to collapse already mentioned, it will sometimes happen that infants under six months

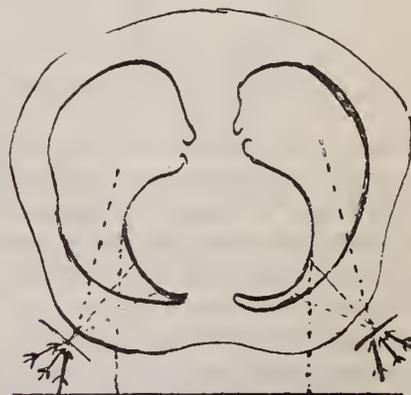

FIG. 1.—Infant.

will show no increased temperature, and even a subnormal temperature, although the physical examination shows the persistence of the inflammatory lesion.

A chill is rarely distinct. At most, there is pallor and cyanosis, cold hands and feet. A convulsion will often be its equivalent at the beginning of an infectious disease.

Examination of the Chest.—A cross-section of the in-

fant's chest will show that it is more circular than that of the adult. (Figs. 1 and 2.)

It is well to examine the chest even when no symptoms (cough or dyspnoea) point to a lesion of that organ.

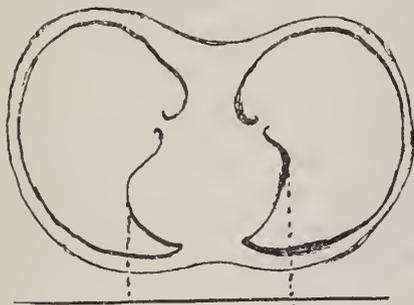

FIG. 2.—Adult.

For the reason already given, it may be desirable, in some cases, to change the usual order and auscultate before percussing.

In the new-born, the *inspection* of the chest will often show the presence of a few drops of fluid in the mammary glands; and in older infants, the presence in some cases of the rachitic chest, with the lateral flattening, the prominent sternum, and, where there is very little fatty and muscular tissue, the rosary at the costochondral junction of the ribs, and the groove at the attachment of the diaphragm to the ribs. (Fig. 3.)

Drawing in of the lower part of the chest is sometimes seen in infants, without respiratory impediment. In such cases it is due to the traction of the diaphragm on

FIG. 3.—Cross-section of a rachitic chest.

the soft flexible ribs, combined with the pressure of the atmosphere which is not counteracted by the forcible expansion of the lungs. Of greater importance is the additional action of the accessory muscles of respiration.

The number of *respirations* in one minute should be counted. Normally there are from thirty-two to forty in the new-born; about thirty during the first two years, and the relation of respiration to pulse from one to three and a half or four. An increased frequency, unless marked, cannot be considered pathological, as it is not uncommon in weak or rachitic infants in whom the breathing is very superficial. During the first few months the breathing may be irregular. Infants will hold their breath for several seconds during the examination. Even when it assumes a character similar to the Cheyne-Stokes respiration, it has not that great diagnostic significance which it has later.

For the *percussion* of the posterior surface of the chest, the child is best held on the arm of the mother, the chin resting upon her shoulder. She should not press the child against her chest; the spinal column should be straight. If there is a pathological curvature, allowance must be made.

In cases in which slight dulness is found on one side as compared with the other, it is advisable to place the infant on the other arm and percuss again.

The percussion should be performed gently, finger upon finger. If the hands are cold, it is best done over the thin shirt. If percussed strongly, the tone from small spots of consolidation will be masked by that of the adjoining normal pulmonary tissue. The finger will often perceive an increased resistance in cases in which fluid is present.

If the infant is crying, a pronounced dulness will be obtained during expiration, posteriorly on the right side below. This is due to the relatively large liver. Percussion during inspiration will give a normal pulmonary note.

In the adult we have the same phenomenon, when, on deep inspiration, at the boundary line between lung and liver, the liver dulness changes to the pulmonary resonance.

Almost all clinicians agree that it is very difficult to percuss the thymus gland in the infant. To render it somewhat easier, it has been suggested to incline the head and chest forward. The same may be said with regard to the percussion of enlarged bronchial glands. If the diagnosis is often corroborated at the autopsy, it is largely because the lesion is so common.

In *auscultating* the lungs, the ear may be placed against the chest. However, for the purpose of more definite localization, it is better to use the binaural stethoscope. In the auscultation of the heart it should always be used. Dr. Koplík has devised a special stethoscope for use in infants, the shape and size of the bell of which is shown in Fig. 4.

For my own use, I have had a pair of hard-rubber ear tips made from plaster casts of the ear. They have the advantage that they fit more accurately, and therefore exclude to some extent the external sounds; and they do not irritate the meatus by friction. (Figs. 5 and 6.)

It may sometimes be necessary to have the mother give the breast for a few moments to stop violent crying.

During the first few months, the breathing is superficial, and not distinctly heard when the child breathes quietly. For this reason, it is sometimes an advantage to have the child cry, so that on deep inspiration the breathing, and any râles which may be present, will be more distinctly heard.

As the infant grows older, the breathing assumes that peculiar sharp blowing character known as puerile. Owing to the larger bronchus, the breathing on the right side is somewhat louder.

The anterior and lateral surfaces of the lung should

always be examined, for it is not uncommon to find a few resonant crepitant râles over a very small area (in the supraclavicular region, in the axilla, or over the lingua). The child may be placed on its back or seated in the lap of the mother.

The auscultation of the lung is even more important than the percussion, for whereas small or deep-seated

The character of the cry is less important. It may be strong and lusty or hoarse or weak and moaning or piercing; continuous or intermittent, and of short duration, with flexion and extension of the legs as in ordinary intestinal colic.

In the infant, the *heart* lies somewhat higher and is more horizontally placed. This is largely due to the relatively large liver and the higher position of the diaphragm. It is also relatively large compared to the lungs, the relation being in the first months as one to three and a half or four. Later the lungs increase much more rapidly in size. In the examination the possibility of *congenital lesions* must be kept in mind.

The inspection of the precordial region will often show a pulsation in the fourth intercostal space, also occasionally in cases with rachitic chest, a pulsation in the epigastric region. The apex is usually felt in the fourth intercostal space, sometimes in the fifth, just outside the mammillary line. In determining the boundaries of the heart, it is necessary to make allowance for malformation of the chest and curvature of the spine, if present. Normally the area of relative heart dulness is much greater than in older children and in the adult (Figs. 7 and 1 and 2). Its extent is shown in Fig. 7.

This comparatively large extent of superficial dulness is due, not only to the relatively large size of the heart, but also to the fact that the layer of lung tissue covering it is thin.

In determining the boundaries, the finger should strike at right angles to a tangent, at the point of percussion. If the finger is directed at an acute angle, a greater

FIG. 4.—Natural size.

FIG. 5.—Posterior surface.

FIG. 6.—Anterior surface.

areas of consolidation or infiltration give no dulness, crepitant resonant râles may be transmitted to the ear from these parts.

It is well to remember that the lesion is usually greater than the result of the physical examination would lead one to expect, for only the involvement of comparatively large areas gives distinct physical signs.

In testing the voice and fremitus, the cry of the child will have to take the place of the counting in older children. The fremitus is best felt with the ulnar edge of the hand, especially in cases in which it is wished to determine the height of a pleural exudate. Coarse râles are often better felt than heard.

The *diagnosis* between pneumonia and pleuritis has often been neatly arranged in two adjacent columns. Notwithstanding, in some cases the distinction is difficult and the needle alone will decide. The same may be said with regard to the character of a pleuritic exudate.

Crying will often bring on an attack of coughing; when it does not, and one wishes to hear it, pressure may be made on the trachea just above the sternum, or the postpharyngeal wall may be touched. The character of the cough is sometimes pathognomonic. Four varieties may be distinguished: First, the simple catarrhal; secondly, the suddenly interrupted dry, short cough, which causes pain (pleuropneumonia); thirdly, the croupy; and, fourthly, the spasmodic paroxysmal (pertussis).

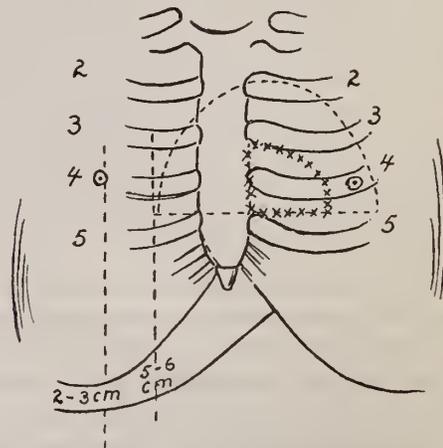

FIG. 7.

or lesser extent of lung tissue is included, and therefore a different result will be obtained (Fig. 1).

The absolute dulness is about the same as later.*

In auscultating, the stethoscope must not be pressed strongly against the flexible ribs, as it is possible to cause a slight roughness of the first sound in this way.

Almost all *murmurs* are organic and systolic. Functional and diastolic murmurs are extremely rare. Murmurs may often be distinctly heard posteriorly on the

*See Troitsky, *Festschrift* to Professor Jacobi, 1900.

right as well as on the left side. They are probably transmitted by the relatively large liver.

The Pulse.—The normal frequency of the pulse in the new-born and during the first months is from 120 to 140, and in the second year from 100 to 120. A marked increase may be due to slight causes. Occasionally, during the early months, it may be irregular without any apparent cause.

As compared to the adult, the increase of frequency of the pulse is greater for each degree of rise in temperature. This is said to be due to an increased irritability of the stimulating, with a diminished activity of the inhibitory, nervous mechanism of the heart.

The frequency, regularity, and tension of the pulse are to be noted, if possible, in sleep. A slow and irregular pulse is especially important from a diagnostic standpoint.

On account of the small size of the artery, the determination of the tension and the height of the pulse wave require much practice on the normal, in order to detect slight changes.

Examination of the Abdomen.—In the inspection of the abdomen of the new-born, special attention is to be paid to the condition of the *umbilicus*, as being the most common portal of infection. The presence of an umbilical hernia or fungus will also be noted. In atrophic babies the contour of coils of intestine is often visible. In intestinal obstruction peristalsis may be seen. It should be noted whether the abdomen is prominent (rhachitis, fluid, gas), or depressed.

Before *palpating* the abdomen, the hands should be warm. If it is thought that certain points are painful, the other parts should be palpated first. This should be done gently with extended fingers, parallel to the surface of the body. In palpating deeper parts, pressure is made during expiration (it is often better to place one hand over the other, and exert pressure with the upper against the lower), held in the same position, and still deeper pressure made at the next expiration.

Percussion (except for deep structures) is performed gently, for the reason already given. In infants the liver is relatively large (Fig. 7). The dulness begins anteriorly on the right side at the fifth rib and extends for from two to three centimetres below the free border of the ribs in the mamillary line, from five to six centimetres in the parasternal line. An additional reason for the apparently still larger size is the more horizontal position of the ribs, which leave more liver surface uncovered. Here, as in the case of the spleen, palpation is more reliable than percussion, owing to the possible proximity of intestinal coils.

The *splenic* dulness extends from the eighth intercostal space or ninth rib superiorly to the eleventh rib inferiorly, and to the axillary line anteriorly. When it cannot be palpated, it is not justifiable to say that it is enlarged. Palpation is best performed with the left

hand posteriorly, pressing forward the lower ribs, the right hand at the free border of the ribs in the axillary line. In some healthy infants under six months of age the spleen is normally palpable. In very anæmic or rhachitic infants a palpable spleen is of no diagnostic value, unless it is certain that it was not previously enlarged.

Occasionally, the infant has an attack of *singultus* during the examination. If the spleen is enlarged, the sudden contraction of the diaphragm brings it down against the fingers.

Examination of the Spinal Column.—The child is to be held perfectly straight and undue prominence of the vertebræ at any point, painful spots, and curvatures noted. The rhachitic curvature (kyphosis or kyphoscoliosis) will disappear when the spinal column is examined in the usual way, the patient lying on the abdomen, the upper part of the chest fixed, and the body raised from the table by elevation at the ankles.

Examination of the Extremities.—Special attention should be paid to the epiphyses, to the possible presence of congenital luxations or paralyses, and to the appearance of the palms of the hands and the soles of the feet.

The Mouth and Throat.—These should be examined in every case. It is only necessary to mention the importance of such examination in the preeruptive stage of the exanthemata. The examination should include not only the pharynx, tonsils, and uvula, but also the entire mucous membrane lining the mouth. The infant is best held with its back against the chest of the mother, who holds the hands. The lateral motion of the head is prevented by the examiner's left hand. In order to avoid the danger of having the secretion of the patient's mouth coughed into the face, a glass screen is sometimes used. At night, the "Welsbach" white light, if it can be had, is to be preferred. For the purpose of throwing the light into the throat, the small oral reflector with a handle is most convenient.

In private practice, unless the tongue depressor can be immediately sterilized, it is better to use the handle of a small spoon, which can be immediately placed in boiling water. Small, smooth wooden slips are also convenient, and can be burned. Sometimes it will be necessary to close the nostrils with the fingers, in order to make the child open its mouth.

The inspection of the mouth may show the presence of congenital malformations or of those due to previous disease. Among the structures frequently seen are the so-called epithelial pearls in the median line of the hard palate; Bednar's aphthæ, also, on the hard palate, laterally; and the sublingual ulcer from the friction of the tongue against the sharp lower incisors, especially in pertussis.

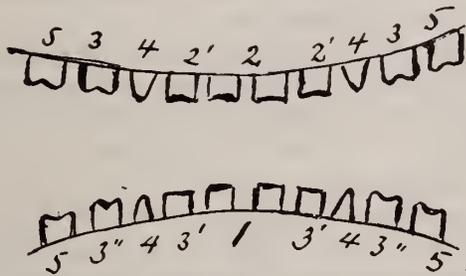

In the infant, the *tongue* is even less "the mirror of the stomach" than it is in the adult. It may be perfectly clean in gastric disturbances, or coated where there are none. A peculiar appearance, frequently observed, is the

so-called geographical tongue. It is benign and has nothing to do with syphilis.

In examining the throat it will be well to have the patient gag, as the contraction of the pharyngeal muscles causes a rotation forward of the pillars of the fauces and tonsils, often bringing into view diphtheritic patches not otherwise seen. In some cases (retropharyngeal abscess, adenoid vegetations) it will be necessary to introduce the finger. As the space is very small, obstruction to the breathing is easy. It should be done quickly; for adenoid vegetations preferably with the little finger. It is seldom necessary to use a protecting ring.

The Teeth.—The order in which the teeth appear is shown in the accompanying diagram (Fig. 8). Slight variations are not uncommon. In rachitis the teeth appear later and at irregular intervals.

The examination of the larynx in infants is rarely necessary. Perhaps it would be desirable in those cases in which diphtheritic laryngitis is suspected, but no mem-

FIG. 8.

brane is seen in the throat. A satisfactory examination is exceedingly difficult, and had better be left to the specialist. There is, however, another method of examination, which will partly, at least, replace it. As it is not generally known, a few words of explanation will not be out of place.

Autoscopy was first made practicable by Kirstein in 1898. Recently Dr. Thorner* has written an article on the subject.

The examination of the larynx is difficult on account of the anatomical condition of the parts (Fig. 10). The position and form of the epiglottis, the hyoid bone overlapping the upper margin of the thyroid cartilage, and the aryæno-epiglottic folds, render the entrance to the larynx small. Besides this, the axis of the larynx at the level of the cricoid cartilage is tilted slightly backward toward the vertebral column. The object of the examination is to bring the axis of the laryngotracheal tube in

line with the buccal cavity. For this purpose, a special tongue depressor has been devised (Fig. 9).

I have had one made of somewhat smaller dimensions. The patient is held as for the ordinary throat examina-

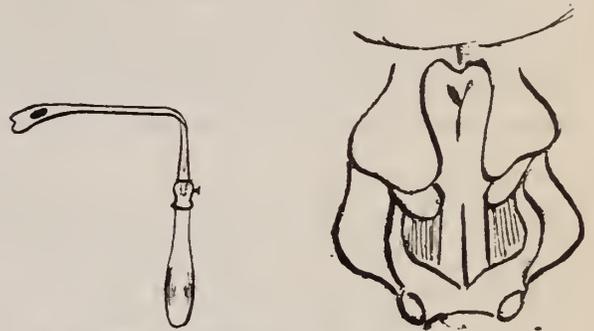

FIG. 9.—About one fourth natural size.

FIG. 10.

tion, except that the infant must be held in the lap, whereas the examiner stands. No mirror is used. Light from a reflector may be thrown into the mouth. The instrument is then introduced to the base of the tongue, and pressure made downward and forward. This, together with the traction on the median glosso-epiglottic ligament, raises the epiglottis. Looking downward, the lower pharynx, the epiglottis, and the vestibule of the larynx are seen; seldom more than this. Ingals has added two flanges to the instrument to prevent closure of the mouth.

In doubtful cases, a *bacteriological examination* will be made to determine the presence of the Klebs-Löffler bacillus, streptococci, or staphylococci.

Examination of the Stomach.—In infants this viscus is relatively small and the fundus is not well developed. It is usually stated that the position is more vertical. However, the transillumination does not show that the difference is very great. (Fig. 11.)

The *chemical examination of the stomach contents* will rarely give any definite information. Infants vomit so easily that, knowing about how much nourishment (milk) has been taken, and the length of time that it has been in the stomach, an approximate idea can be obtained as to the muscular activity (motility); and an inspection of the vomited matter will show the state of the gastric digestion. In cases in which obstruction is suspected, also in rare cases of dilatation or change in position, it may be necessary to introduce the stomach-tube. For this purpose, a soft rubber catheter is used. The introduction is easier because there is little or no resistance. It is a disagreeable sensation, but the infant can only express its displeasure by crying. The tube is held like a pen in the right hand, and is guided to the posterior pharyngeal wall with the index finger of the left, then pushed backward and downward. It is well to have the distance from the lips to the cardiac end of the stomach marked upon the tube, so that you know when the end enters it. The gastrodiaphane, by the transillumination of the stomach, offers another means for ascertaining its size and position, and the situation of the pylorus. Its in-

*New York Medical Journal, March 10, 1900.

roduction requires special skill and it will rarely be needed by the practitioner.

Recently, Dr. Koplik has perfected a form of this instrument specially adapted for infants, the construction and method of introduction of which will be found described in the *New York Medical Journal*, May 6, 1899. The illustration (Fig. 11) is taken from that article and shows the normal position and size of the stomach. The inspection of the anal region may show the presence of

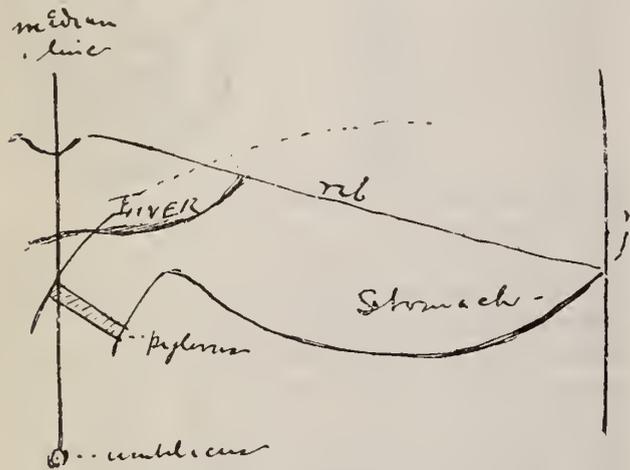

FIG. 11.

syphilitic lesions, prolapse or fissure of the rectum, or intestinal worms. For the rectal examinations (polypi, intussusception) the index finger, covered with vaseline, is used. In those few cases in which it is wished to inspect the mucous membrane, or to examine higher up than the finger can reach, the largest-sized endoscopic tube (shortened) may be used as a rectal speculum, or even the smaller Kelly tubes.

Inspection of the genitals will show the possible presence of congenital peculiarities, epispadias and hypospadias, undescended testicle, hydrocele, congenital phimosis. A partial agglutination between the prepuce and glans is present in almost every male infant. In female infants, also, an agglutination or thin band is sometimes seen between the labia minora. The *inguinal glands* may now be examined.

Examination of the Ear.—In connection with the inspection of the external portion of the ear, the parotid and mastoid regions may be examined. In all cases in which fever is present (more especially, however, after measles or scarlatina), for which the examination of the other organs of the body shows no cause, the middle ear should be inspected. Pain may be absent, or, if present difficult to ascertain with certainty.

Owing to the structure of the auditory meatus, and the more horizontal position of the tympanic membrane, the examination is more difficult. The patient is held in the lap and the head steadied. The ear is drawn backward, outward, and downward (instead of upward as in the adult). The smallest-sized ear speculum is then introduced, and looking upward, the superior wall is followed to its inner extremity.

Examination of the Eyes.—The eyes should first be inspected without touching them, and congenital peculiarities, if present, noted (ptosis, a difference in the size of the pupils, eccentric position of the pupils, also strabismus, nystagmus). The pupillary reflexes should be tested. At the age of six weeks, the eyes of most infants can be fixed by a bright object. With it the action of the muscles of the eye can be tested. If the head is steadied, the lids may be everted and examined. If it is necessary to use a speculum to keep the lids apart and a second person cannot be had to steady the head, the infant may be placed in the lap of the mother who holds the hands; and the examiner clamps the head of his patient between his knees, over which a towel has previously been spread. If the eyeball rolls upward, it is necessary to wait a moment for it to descend.

Fortunately, but few cases (increased cranial pressure, tumors, tuberculous meningitis, chorioid tubercles, amaurotic idiocy) require an examination of the fundus. Unless the examiner is skilled in ophthalmoscopy, this is best left to the specialist.

Some healthy infants habitually sleep with their eyes partially open. As an almost constant symptom it is present in the last stages of severe intestinal and cerebral diseases. The cornea becomes dimmed and covered with shreds of mucus.

Inspection of the nose may show the depressed bridge of syphilis, or the movement of the wings in dyspnoea. The orifices are small and easily obstructed. The permeability may be tested with a fine probe. If the infant can take the breast without marked dyspnoea, there can be no great obstruction in the nose or in the rest of the respiratory tract.

Examination of the Urine.—The urine of the newborn during the first few days may contain a small quantity of albumin. At this time, uric-acid infarcts are common. They will give pain on urination and an excess of uric-acid salts in the urine. A small amount of albumin may be present after the external application of cold to the surface, and after convulsions; and a small quantity of sugar in cases of dyspepsia. The amount of urine voided is relatively large, of pale color, and low specific gravity, 1,002 to 1,007. When an examination of the urine is to be made, there is no use in wasting time with sponges, rubber bags, and squeezing out the diaper. The simplest and best method is the introduction of a perfectly clean rubber catheter.

Examination of the Fæces.—The frequency of gastrointestinal disorders in infants renders an examination of the fæces of great importance. Normally, on a milk diet, the fæces are yellow, soft, slightly acid, and without pronounced odor. Some healthy infants have regularly as many as four movements daily of good consistence. In an abnormal stool, besides the number daily, it should be noted whether they are voided with or without pain. Macroscopically, the color, consistence, odor, the presence of mucus, blood, undigested particles, fat (normally

about ten per cent.) and, microscopically, the presence of undigested starch, the eggs of worms, bacteria, epithelial cells, are to be noted. The wet diaper from a watery stool should not be thought to be due to urine. When a specimen of the fæces is desired for microscopical examination, a soft rubber catheter is introduced, and by rotating it some fæcal matter may be collected in the eye.

Examination of the Blood.—The amount of blood in the infant is relatively small, 1 to 19.5 of the weight of the body, as against 1 to 13 in the adult. It contains less fibrin, less hæmoglobin (except in the new-born) and more white blood cells.

The examination of the blood is the same as in the adult. It may be mentioned, however, that in very anæmic babies the determination of the number of white blood cells may be more difficult on account of the larger size of the capillary tube. An examination of the fresh and stained specimens will give an idea of the number of corpuscles.

In a few cases one may wish to examine the sputum. For this purpose a soft rubber catheter is introduced into the mouth, and the posterior pharyngeal wall touched. This will usually bring on an attack of coughing, and a small quantity of sputum may be caught in the eye of the catheter.

It is certainly true that infants take to some physicians more than to others. I believe that those who feel kindly toward them will be most successful. A little playfulness is sometimes necessary. Perhaps some physicians may consider such trifling beneath their dignity, but it often very greatly facilitates the examination. Time and patient observation are needed to learn their peculiarities; but when these are known, the little patients become exceedingly interesting, and, in their helplessness and entire dependence on others, inexpressibly touching.

In conclusion, I wish to thank Dr. Koplik for much valuable instruction and for the advantage derived from the examination of a very large number of cases at the Good Samaritan Dispensary.

27 WEST ONE HUNDRED AND FIFTEENTH STREET.

A CASE OF PAROXYSMAL HÆMOGLOBINURIA.

By WILLIAM JUDSON LAMSON, M. D.,

NEW YORK,

ATTENDING PHYSICIAN TO THE DEMILT DISPENSARY.

THIS disease is of such unusual occurrence that it has seemed worth while to report in detail the following case, which occurred in the practice of Dr. William B. Clark, and upon which he kindly allowed me to make the following observations:

Family History.—The patient was a clerk, forty years old, married, a native of the United States. His father was German, his mother Scotch. His father died a violent death during an attack of melancholia. He has

four brothers and two sisters alive and well, except that one brother has a syphilitic disease of the cranial bones.

Personal History.—The patient lived in South America as a child, but had none of the tropical diseases himself, although several members of his family had yellow fever. Except for the mumps, he was perfectly well until 1882, when he contracted gonorrhœa and had a small, discharging sore on the penis, probably chancroidal in nature, which lasted only a short time. He did not have specific treatment, and no secondary symptoms appeared.

In November, 1892, while living in Dakota, he drove several miles on a cold day, got chilled, and passed urine which was deeply colored with blood. The attack of hæmoglobinuria lasted a few hours and then passed away without any other marked symptom. These attacks recurred at intervals of a few weeks, following exposure and cold. In December, 1895, he came East, emaciated, jaundiced and feeling run down, the attacks occurring every few days, and finally exhibiting a tertian periodicity. He was seen by a physician who made the diagnosis of malarial anæmia, and was treated with bone marrow, cod-liver oil, cream, and careful diet, but no quinine. His kidneys, heart and lungs were pronounced sound. As a result of this tonic treatment his general health improved and he gained in weight, but the attacks of hæmoglobinuria occurred as frequently as before. In 1896 he went West again and remained until September, 1900, when he again returned East for treatment, the attacks occurring as often as ever, sometimes daily. In summer he is, as a rule, free from the attacks, but they are occasionally produced by worry or mental shock. The chief predisposing factor seems to be exposure to cold. A *typical attack* begins about 10 A. M. with a chilly feeling, often becoming a rigor; cold extremities and cyanosis of fingers, nose and ears; increase in jaundiced hue, and nausea. He then passes urine of port-wine color, somewhat more frequently than normally and in greater amount. The chill lasts from one half to three hours, and is succeeded by a feverish sensation. At times an urticarial eruption appears on the dorsum of the hands or on the right cheek; or he may have tender painful areas over the bridge of nose, around the right orbit or in the left groin. Normal urine is passed again, sometimes in twenty minutes, often not for several hours, depending on how quickly he becomes thoroughly warm.

Between the attacks he feels perfectly well, except for mild symptoms of anæmia. His skin is sallow. He has been troubled with flatulent indigestion which has yielded to treatment. Occasionally he has an eczematous eruption on right leg. His fingers are somewhat clubbed. His lungs are normal. The apex of the heart is normally placed, but there is a loud double murmur over the base. His pulse averages 86, temperature normal. The *urine* is clear, light or dark yellow, of acid reaction, sp. gr. 1020 to 1030, no albumin, no sugar, no hæmoglobin, and shows microscopically only a very few leucocytes and some pavement epithelium. The *blood* has been examined frequently, both during and between the attacks, but no plasmodia or unusual deposits of pigment observed. The hæmoglobin is 80 per cent., the red cells 4,200,000, and there is no leucocytosis. During the attack the plasma contains hæmoglobin in solution, and the red cells do not form rouleaux as readily as normally. Some of the red cells are very pale—"Schattenformen."

The observations in Table I were made during an attack of hæmoglobinuria which occurred December 14, 1900:

TABLE I.

Time.	Temperature.	Pulse.	Amount.	Color.	Sediment.	Reaction.	Specific gravity.	Albumin.	Microscopical appearances.	Symptoms.	Blood.

2:10 "	99	95	3 "	Yellow	"	"	1025	0	"	Feeling well again	0

This attack was of unusual severity and duration, the patient passing normal urine generally four hours after the onset. The remainder of the attack of December 15th was not observed.

The attack, a synoptical observation of which is shown in Table II, occurred on December 19th, and the patient was put to bed and made warm as soon as possible, thus shortening the duration considerably.

The presence of hæmoglobin in the urine samples (Table II) was determined by the following tests: 1. Spectroscopic examination, which gave the typical absorption bands of methæmoglobin. 2. Heller's test, boiling the urine with KOH and thus precipitating the phosphates, which were colored red by the hæmoglobin. 3. Guaiacum test with ozonized turpentine. 4. Guaiacum test with ozonized ether.

The coagulum produced by boiling, unlike the usual albuminous precipitate produced by such reaction, instead of being white and flocculent and sinking to the bottom of the test tube, was a brownish, curdy mass, which rose to the summit of the fluid.

Remarks.

This disease has been variously named by different authors. Dr. George Harley (2) first described it as intermittent hæmaturia and Dr. Pavy as paroxysmal hæmaturia. When, however, pathological research showed the absence of the cellular elements of the blood in the urine, the name was changed to intermittent hæmatinuria, and later to its present name, paroxysmal hæmoglobinuria, in order to distinguish it from similar conditions of the urine in which the elements of the blood, as such, are found. The earliest case was reported by Charles Stewart in 1794. It was that of a man fifty-one years of age, who had attacks of hæmaturia lasting three days each for a period of eight months, accompanied by constant pain in the loins and marked emaciation, being thus unlike the disease as known at present. Other cases, giving a previous malarial history, and more nearly resembling the typical case before mentioned, were reported from time to time. The majority of cases seem to have occurred in England, Germany and France contributing only a few cases to the history of the disease.

Ætiology.—The disease attacks men in the majority of cases, and the most common age is from twenty to forty years, although it has occurred for the first time as early as two years and as late as fifty-two years. Heredity does not seem to play any part in its ætiology. Neither does occupation, although the majority of cases are said to occur among the lower classes. A previous malarial history has been obtained by some authors in a third of their cases (1), while others allege a specific origin for the disease; for instance, Copeman (2) says: "In all my own cases syphilis, either primary or congenital, has been present." Still others mention rheumatism, gout or the oxalic-acid diathesis as predisposing factors. Whatever the underlying condition may be, the exciting cause of the attacks seems to be always exposure of some part of the surface of the body to cold. It is rare in summer, the onset beginning with the approach of cold

weather in the fall or winter, and for this reason it has been given the name of winter hæmaturia (3).

The symptoms are, as a rule, clearly defined and unmistakable. The patient, after exposure to cold, becomes chilly, yawns, and has nausea which may go on to retching or vomiting. The feet, hands, and ears become cyanotic and cold, and bloody urine is voided. These symptoms come on generally in the forenoon and gradually disappear as the patient becomes warmed—a fever, and sometimes sweating, ending the paroxysm. The temperature, which at the onset was 95°-96° F., may rise even as high as 103° or 104° F., depending on the severity of the attack. The average is about 100°-101° F. The urine, which on rising was perfectly normal, becomes during the algid portion of the attack of a port wine or blackish color, contains hæmoglobin in large amount, is of acid reaction generally, and of high specific gravity. In some cases the specific gravity has been low (4) and (5). When examined microscopically, there are found hyaline and granular casts and much granular detritus composed of broken-down red cells, but no red cells as such, thus differing from hæmaturia, in which the elements of the blood pass unchanged into the urine. The rapidity with which this condition passes away under the influence of warmth and stimulation is really startling, for the urine resumes its normal color and quality sometimes in from half an hour to two hours. The attacks occur with varying frequency, depending on exposure. They have been known to occur as often as three times a day in severe cases; or they may occur daily, as in the case before referred to, or one to three times a week. Intervals of weeks or months may pass, however, during which the patient, if warmly and properly clothed, is free from attacks.

The pathology of the disease is obscure, no autopsy on a case being recorded. Sir William W. Gull (6), in 1866, concluded that the disease was due to the inability of the kidneys to break up the hæmatin of the blood into urine pigment. Dr. Pavy (7), in 1867, ascribed a nervous origin to the disease—"an unnatural susceptibility of the kidneys to temporary congestion from exposure to cold." Others have considered it a part of a rheumatic or gouty diathesis. The close relation between paroxysmal hæmoglobinuria and Raynaud's disease was emphasized by Barlow (8) in 1883. He reported a case of Raynaud's disease in which there was accompanying hæmoglobinuria during the attacks, and other authors have noticed the same facts. There seems to be a close connection also between this disease and paroxysmal albuminuria—in fact, Dr. Copeman (9) calls paroxysmal albuminuria the "petit mal of paroxysmal hæmoglobinuria." Thus Wickham Legg (1) reports a case of a man who was chilled by falling into a stream and developed hæmaturia, which passed off, leaving a temporary albuminuria, which lasted six weeks and was followed by recovery. Dr. Lee Dickinson (10) reports three cases of transient hæmoglobinuria from unusual exertion, the

corpuscles being destroyed by the excess of CO₂, produced by the muscular activity.

The researches of Ehrlich (11), Bristowe, Copeman (9), and others, would seem to point to an injurious effect of cold on the discoplasma of the red cells, with consequent liberation of the hæmoglobin, as the true pathological factor in this disease. They passed an elastic band around the base of a patient's finger and immersed it in ice water for one quarter of an hour and then examined the blood from this finger. The corpuscles were of irregular shape and size. Some were colorless, there was no rouleaux formation, and the plasma was tinged pink. The blood from other parts of the body was practically normal. Attacks of hæmoglobinuria were artificially induced by cold baths, etc., and blood counts, made before and immediately after the first symptoms appeared, showed a marked diminution both in the number of red cells and their contents of hæmoglobin. This primary change in the blood, therefore, is the accepted pathological factor at present.

In this connection it is interesting to note two cases reported by Klemperer (12). One, which was perhaps due to ptomaine poisoning, came on suddenly like an infectious disease, with rigor, fever, swelling of the liver and spleen, icterus and hæmoglobinuria, lasting three days, followed by complete cure. The other occurred during convalescence from typhoid fever, lasted three months, and was only slightly benefited by graduated cool baths.

Prognosis.—No deaths from this disease are recorded. There seems to be no danger to life from the immediate attacks. There is a dearth of literature, however, on the latter end of such cases. Death is due to some complication. On the other hand, no case has been cured by drugs.

Treatment.—A great variety of drugs has been used. When syphilis has existed, good results have been obtained by the iodides in large doses. A distinct history of previous malaria calls for the exhibition of quinine. Iron, arsenic, and tonics of all sorts, have been used with temporary benefit. Warm clothing, especially on the hands and feet, with avoidance of exposure to cold, has diminished the frequency of the attacks. Graduated cool baths have also been tried. All have failed, however, to effect an ultimate cure; and a change to a climate where the temperature is moderate and equable seems to be the best treatment which we can offer for this singular disease.

GENERAL ANÆSTHESIA:
THE PRELIMINARY AND AFTER-TREATMENT,
WITH REMARKS
ON CHLOROFORM AND ETHER.*

BY E. PAYNE PALMER, M. D.,

PHOENIX, ARIZ.

I HAVE taken such a heading for my subject this evening because I think it is one of which too much cannot be said or written, as the average physician pays too little attention to its importance and dangers. It is a subject which should be taught separately and thoroughly in medical colleges, but I am sorry to say that there are but few that give it the proper attention, and, as a result, when the graduates leave school they know little or nothing of this all-important subject. We find that most of the anæsthetists of our large hospitals are selected from the junior internes, and installed upon their roll of duty without any practical knowledge or special instruction in this branch of medicine. As a consequence their knowledge must be obtained in a haphazard manner, and in some cases their experience is very disastrous.

Therefore the junior interne who is to act as anæsthetist should have special instructions from the surgeon in charge, in case his knowledge in this work is deficient. I believe that the anæsthetist should be as much of a specialist as the practitioner of any other branch of work in medicine. There is certainly no other branch of medicine that calls for more immediate skill and attention, keener observation, and greater judgment. Anyone can administer an anæsthetic, but it is comparatively rare to see a patient properly anæsthetized.

I do not lay claim to any new ideas or originality; I will only present to you, in a concise form, well-known facts which have been in practice for some time, and have been shown to be necessary for the safety and comfort of the patient. No person who has not a wholesome fear of anæsthetics can be trusted to administer them. Every anæsthetist must realize that in giving an anæsthetic there is always an element of danger, and that he alone is responsible for the life of the patient. He should, therefore, spare no pains in the most minutè attention to details, and should look for and be prepared to treat any troublesome or dangerous symptoms that may arise. He has the right to demand from the surgeon compliance with all procedures that tend to lessen the risk of accident. His exclusive attention belongs to the patient; there is no time for anything else. It is no uncommon

occurrence to see the anæsthetist craning his neck to watch the operation, and some so far forget their duty as to lose sight of their patient's condition.

It is a source of great comfort to the surgeon to have an anæsthetist in whom he can place implicit confidence.

Preliminary Treatment.—The anæsthetist rarely sees the patient until the time set for the operation, at which time he should inquire about the preparation of the patient, as the proper previous treatment has a very important bearing on the successful issue of the case. Melish affirms that most of the pronounced dangerous effects of ether, and, to a less extent, chloroform, upon the kidneys, are due to poor preparation of the patient, faulty administration, bad after-treatment, or all of these combined.

If the patient is under your care, and time is allowed, the bowels should be thoroughly flushed out by first giving small doses of calomel and following it with a saline, the day before the operation. On the morning of the day set for the operation, the patient should have a high rectal enema, and if the operation is to be performed some hours later, another enema should be given about an hour before the administration of the anæsthetic is begun. That day the patient should not be allowed any solid food, and no food for at least three hours before the anæsthetization is begun. The bladder also should be evacuated immediately before the anæsthetic is given. In emergency cases and those requiring immediate operation, in which no preparation has been made, gastric lavage should be practised, using plenty of warm water, and the bowels should be flushed out by means of a high rectal enema. A good procedure, recommended by Rosenberg, of Berlin, is that of spraying the nasal mucous membrane with a five- or ten-per-cent. warm solution of cocaine about five minutes before administering the anæsthetic. Especially is this useful where a catarrhal or irritable condition of the nasal and pharyngeal mucous membrane exist; also in hypertrophy of the turbinates, as it checks the secretion of mucus and allays the irritability of the mucous membrane.

By our following closely these rules, vomiting can usually be prevented to a great degree both during and after the administration of the anæsthetic.

When the patient is nervous and hysterical and unduly afraid of the anæsthetic, one fourth of a grain of morphine and one two-hundredth of a grain of atropine may be given about thirty minutes before beginning the anæsthetic to quiet the patient. No one should make a practice of giving morphine before anæsthetizing, because unless there is some special indication for it, there can be no benefit derived, and in some cases it may do harm. Explain the nature and action of the anæsthetic to the patient, tell him what is to be expected, and above all assure him that there is no danger; and by so doing you may prevent struggling.

Examination of the Patient.—In all cases examine the patient yourself; do not rely upon the examination of

*Read before the Arizona Academy of Medicine at Phoenix, Ariz., December 22, 1900.

another person, it matters not who he is. Make a thorough and systematic examination of the respiratory and circulatory systems, note the condition of the nasal passage, whether or not there is any obstruction. In mouth-breathers a wedge should be placed between the teeth to allow free breathing. Note the frequency, regularity and depth of the respirations. Take both the radial and facial or temporal pulse and note their force and frequency and whether there is any irregularity. It is a good plan to accustom yourself to taking the pulse of the facial and temporal arteries, as they are convenient when anæsthetizing. Examine the mouth and pharynx for false teeth, hypertrophied tonsils, and any other foreign objects that may be present. In the *New York Medical Journal* for December 1, 1900, I reported a case of a child in which there was cessation of respiration during chloroform anæsthesia due to chewing-gum in the larynx. Examine both eyes and observe the condition of the pupils; an artificial eye may deceive you. If time is allowed, the urine should always be examined. Inquire as to whether the patient has taken an anæsthetic previously. If so, he may be able to give you some information that may have important bearing on its administration.

Preparation of the Anæsthetist.—The anæsthetist should wear a sterilized gown and prepare himself as for an operation. Be provided with and have within easy reach the following articles, so that in case of accidents or unfavorable symptoms, you will be able to meet them without delay: The best known quality of chloroform and ether; an inhaler for both; a drop bottle for chloroform; a curved needle threaded with a stout silk ligature; a mouth gag or wedge; a sponge holder; gauze sponges; two hypodermic syringes, one containing a solution of strychnine and the other digitalin; also an empty syringe and tablets of strychnine, atropine and nitroglycerin, and brandy or whiskey.

Selection of the Anæsthetic.—The anæsthetist should individualize each case, and after examining the patient and inquiring about the nature of the operation, select the anæsthetic that can be administered with the greatest amount of safety to the patient and the best advantage to the operator. We find that many prefer chloroform and use it almost exclusively, while others prefer ether to the exclusion of chloroform. I have had more experience with chloroform, and naturally prefer it in cases where either of the two would answer equally well.

Remarks on Chloroform.—When chloroform is given the patient must always be in the recumbent posture and remain so throughout the entire operation. I have found that of the two anæsthetics, chloroform is the more agreeable to the patient, produces its effect more rapidly, causes less irritation of the respiratory mucous membrane, less mucus is secreted and there is less subsequent vomiting and depression, the patient does not struggle so severely, and there is not the possibility of the dangerous and troublesome sequelæ, such as nephritis, bronchitis, pneumonia, etc.

Chloroform is indicated—

In extensive bronchitis, bronchorrhœa, pneumonia, or any extensive inflammatory condition of the pulmonary tract, because of its causing less irritation of the mucous membrane and less mucus to be secreted.

In acute and chronic nephritis, because it is less irritating to the kidneys.

In aneurysm, atheroma, endocarditis, and high tension pulse, because it causes a perceptible fall in the blood pressure.

In operations on the brain, because it causes cerebral anæmia, while ether causes congestion and venous oozing.

In operations in the abdominal and pelvic cavities, because it causes a more complete relaxation of the abdominal muscles.

In those addicted to the use of alcohol and narcotics, because they usually take ether badly.

Chloroform in the hands of the inexperienced anæsthetist is the most dangerous, unless administered with great care and uniformity, because of its depressing effect upon the heart and the lowering of blood pressure. It produces death by depression and paralysis of the vasomotor centres or by paralysis of the heart muscles. Its effect upon the respiratory system is secondary and due to anæmia of the respiratory centre in the medulla oblongata. The dangers from chloroform are chiefly immediate, while the dangers from ether are usually remote and due to sequelæ, and are therefore not usually assigned to the real cause.

The first signals of danger when under chloroform anæsthesia are complete relaxation of the pupils, a sudden ashy gray pallor of the face, and a sudden or rapid failure of the pulse. At the same time the respirations become feeble and intermittent.

If, when under chloroform anæsthesia, the pulse becomes rapid, weak, and irregular, with a sudden blanching of the face or lips, or the respirations become shallow, feeble and interrupted, the mask should be removed. If the symptoms disappear, but again appear when chloroform is continued, ether should be substituted. Some patients seem to do better when chloroform is first administered until anæsthesia is obtained, and then a change is made to ether and its use is continued throughout the operation. Especially is this so in alcoholic subjects and in those addicted to the use of drugs, as some of them require an enormous amount of ether to produce anæsthesia, but do well under its influence after anæsthesia has been obtained.

Remarks on Ether.—Ether can be given in the sitting posture, when deemed necessary, without any necessarily bad results. After anæsthesia has been obtained in a horizontal posture, the patient should be gradually brought to the position desired, and the anæsthetic continued.

Ether is indicated—

In emphysema with dilatation of the right side of the heart, fatty degeneration of the heart muscles and dilatation of the heart without compensatory hypertrophy.

In extreme prostration and anæmia.

In shock, collapse and hæmorrhage.

When given under the latter conditions, heat should be applied to keep up the body temperature, as under ether narcosis there is a fall of from one third of a degree to one degree Fahrenheit.

Very stout subjects should be given ether, as fatty infiltration of the heart has been found after prolonged chloroform anæsthesia.

One great advantage that ether has over chloroform, and one that is highly appreciated at times, is that it can be given by the unskilled anæsthetist with greater safety, and at the same time allows anæsthesia to be more profound. It does not require as much skill and care in its administration, because of its stimulating effect on the heart and blood pressure. Under ether narcosis the respirations are to be watched closely, as it kills by depression and paralysis of the respiratory centre, while its effect on the circulatory system is secondary.

Collapse under etherization rarely occurs without warning. The symptoms are: Shallow, gasping respirations; the pulse becomes small, rapid, and irregular; cyanosis may or may not be present, and the pupils dilate. If, when administering ether, you find that it causes a persistent cough with an excessive amount of mucus secreted, or an undue amount of retching and vomiting, which does not cease when the proper means are employed, substitute chloroform. Because of the inflammability of ether, when operating at night, the light, if an open flame, should not be above the operating table.

Administration of the Anæsthetic.—Before beginning the administration of the anæsthetic the lips and nostrils should be thoroughly anointed with vaseline to prevent blistering. The administration should be begun while the patient is in bed in a room other than that in which the operation is to be performed. The room should be devoid of noises, and talking or whispering must be prohibited, as it is apt to excite the patient and interfere with the progress of anæsthetization. The anæsthetist should always induce anæsthesia slowly and gradually, with as little discomfort to the patient as possible. Gradually bring the inhaler closer to the face, so that the patient may become tolerant. When coughing or holding of breath occurs, it is a signal that the vapor is being given in too highly concentrated a form, and is producing an irritation of the mucous membrane of the upper respiratory tract. Therefore remove the inhaler from the face until the signs of irritation have ceased, and afterward proceed more cautiously. Sighing is a danger signal, showing that the patient is getting too much of the anæsthetic; so, whenever noticed, the inhaler should be removed from the face for a few seconds to admit fresh air.

Never allow the operator to proceed until complete anæsthesia has been reached. Deaths have occurred when the operation was begun before anæsthesia was complete; this is apparently due to sudden inhibition of the heart,

produced reflexly by peripheral irritation of a sensory nerve. After surgical anæsthesia has been obtained, just so much of the anæsthetic must be given as is necessary to keep the patient in that stage and allow no risk of danger. The patient should never be allowed to emerge from the effects of the anæsthetic, and then flooded with vapor in order to bring him rapidly under its influence again. This is a most dangerous procedure and must never be adopted. If it were possible to classify properly the causes of death under anæsthesia, it would frequently be assigned to the crowding on of the anæsthetic in order to produce anæsthesia rapidly. The head should be extended, and turned to one side at frequent intervals to allow the mucus to escape from the mouth, after which the pharynx should be cleansed of mucus, by sponging it with a soft sponge, carried on a sponge holder.

Be sure that air is entering the lungs; do not be deceived by the movements of the chest walls; they may continue to move and yet no air enter the lungs. Watch the tongue and see that it does not obstruct breathing. At the beginning of the administration of the anæsthetic, the pulse may be quite rapid, but it will gradually slow until surgical anæsthesia is reached, when it will approach the normal. A soft, slow pulse will allow of free administration, but a full and bounding pulse demands care and watchfulness.

When the patient has become completely anæsthetized, the pupils should be moderately contracted and remain so, the respirations deep and regular, the pulse full, regular, and slow, though it may be rapid without indicating danger unless it becomes weak or irregular, and there should be a general muscular relaxation.

From the beginning the pupils, pulse, respirations, and color and condition of the face and lips, must be carefully and continuously watched. Do not depend upon any single reflex or condition for a danger signal. Always be on the alert.

A contracted immovable pupil shows that you have complete surgical anæsthesia, and a dilated immovable pupil indicates danger, while a dilated movable pupil indicates partial anæsthesia. Sudden wide dilatation of the pupil is a very bad indication, and calls for immediate resuscitative measures. When the pupils dilate suddenly, the pulse increases in rapidity, the respirations become rapid and jerking, and the patient attempts to swallow, the anæsthetic should be administered more freely, as it shows that vomiting is about to occur. When you see that vomiting is inevitable remove the inhaler, lower the head and turn it to one side, away from the field of operation, to permit the vomited matter and mucus to flow from the mouth, and draw the lower jaw forward by pressing behind the angles. As soon as the patient is quiet, cleanse the mouth and pharynx and again administer the anæsthetic.

An increase in the frequency of breathing usually shows that the patient is coming from under the influence of the anæsthetic. It may occur under surgical anæ-

thetia, and be due to deep reflex from manipulation of some of the abdominal or pelvic contents, or from dilatation and manipulation of the sphincter ani.

Resuscitation and Stimulation.—The anæsthetist should be able to state the exact condition of his patient at any time, and by careful attention and watchfulness detect the slightest unfavorable symptom. As soon as an unfavorable symptom appears, the operator should be informed of it, and the operation suspended immediately. No time should be lost in employing resuscitative measures. Those most frequently used are inversion of the patient, artificial respiration, rhythmical traction of the tongue, and hypodermic injections of strychnine, atropine, digitalin, and whiskey. Always be cool and collected; never allow yourself to become at all excited, but know how and when to act.

Under surgical anæsthesia, the muscles of the tongue become relaxed and the tongue may fall backward and obstruct the breathing. To correct this trouble, extend the head backward as far as possible, and carry the lower jaw forward by pressing behind the angles.

When the respirations begin to show signs of weakening, as manifested by slow, shallow, and interrupted breathing, the inhaler must be removed from the face. If the symptoms do not improve at once, inject hypodermically from a thirtieth to a twentieth of a grain of strychnine sulphate, and repeat when necessary. Then invert the patient or lower the head of the table and begin artificial respiration uniformly and regularly at the rate of about twenty to the minute. I prefer Kelly's or Sylvester's method of performing artificial respiration. Rhythmical traction of the tongue at the same rate should be practised, as it stimulates respiration. The tongue should be grasped with a towel, or a stout silk ligature passed through the tongue from side to side, and traction performed by this means. Never use a tongue forceps, unless you wish to have a lacerated tongue and complaint made of the soreness caused by it. The diaphragm can be made to contract suddenly, allowing air to enter the lungs, by grasping the abdominal wall with both hands and raising it up. Atropine sulphate, given hypodermically in a dose of a hundredth of a grain, is a valuable respiratory and vasomotor stimulant, and should be given when deemed necessary.

If the pulse decreases or increases in frequency and gradually weakens, and the lips and face blanch slightly, give from a thirtieth to a twentieth of a grain of strychnine sulphate hypodermically, or a hundredth of a grain of digitalin, or the two combined. If the desired effect is obtained, continue the anæsthetic, and watch your patient with increasing care.

When the pupils dilate suddenly, the pulse becomes rapid, weak, and irregular, and the face blanches suddenly, remove the inhaler and begin resuscitative measures immediately and energetically, for in all probability the patient is in a very bad condition. Therefore, use every measure at hand that is apt to be beneficial. Give

strychnine and digitalin hypodermically, invert the patient, perform artificial respiration or rhythmic traction of the tongue, and introduce into the circulation about a quart of normal saline solution at a temperature of about 115° F. Under these conditions strychnine can be given in large doses, and frequently repeated. Continue your resuscitative measures until you are certain there is no longer any possible danger, or until you are sure that life is extinct. In some cases artificial respiration has to be continued several hours.

After-treatment.—When the operation is completed, the patient should be returned to a warm bed, in a well-ventilated room, and carefully and continuously watched until consciousness has been regained and all immediate danger from the anæsthetic has passed.

If the patient fails to recover as he should after a sufficient time, hot-water bottles should be used to stimulate circulation and keep up the body temperature. Also give strychnine and digitalin hypodermically, and in some cases use whiskey. Stimulating, warm high rectal injections may prove beneficial.

After operations resulting in the loss of a quantity of blood, where there is surgical shock and great weakness, about a quart of normal salt solution at a temperature of about 115° F. should be infused into the circulation. A good practice to follow after prolonged operations, is to give a high colon injection of about four quarts of warm normal saline solution. Especially is this valuable when operating under septic conditions, and in those cases of damaged kidneys where anæsthesia is absolutely necessary, and after which the kidneys may fail to perform their function properly or at all, resulting in suppression of urine. You will find that when the high colon injection of warm normal saline solution is given, thirst is not so intense, shock is lessened, the patient regains consciousness and strength more rapidly, and the kidneys act sooner and more freely, thereby ridding the system of the anæsthetic sooner than otherwise.

Vomiting is one of the most frequent and troublesome sequelæ of anæsthesia. To prevent this, so soon as the patient is returned to bed, he should be forced to inhale the fumes of vinegar for one or two hours, or as long as is necessary. This acts admirably in most cases. During the first twelve hours, nothing should be allowed in the stomach. If thirst is excessive, the high colon injection of several quarts of warm normal salt solution should be given. After that time, small pieces of chipped ice can be given at frequent intervals for some time, until the stomach is shown to be tolerant, before nourishment is allowed to enter it. Lewin recommends gastric lavage with a sodium bicarbonate solution, if vomiting is persistent.

GASTRIC ULCER; REPORT OF TWO CASES.

BY E. S. GOODHUE, M. D.,

KOLOA, KAUALI, H. I.

CASE I.—Mrs. S., aged twenty-four years; married two years; pregnant six months.

History.—Anæmic and chlorotic since puberty, with amenorrhœa, dysmenorrhœa and metrorrhagia at different times. Neurasthenic and hysterical, with obstinate constipation. At each menstrual period has had nausea and occasional vomiting. September 14, 1893, she had a miscarriage after doing a washing. Remained in bed nearly two months, convalescence being greatly retarded by the patient's inability to retain food on her stomach. There was gastralgia, but symptoms were not pronounced enough for diagnosis of anything but dyspepsia.

July 25, 1894, the patient being down-hearted and hysterical, I recommended that she take a trip to her home in Kentucky. She went, and began to gain at once, remaining "never better in her life" up to the day she left for California, November 21st. Then she began to have nausea and vomited "black stuff like coffee grounds." A physician who was on the train prescribed a sinapism and ice pellets. This did not relieve the condition much, and when the patient reached home, at 3.20 P. M., November 25th, I found her in the following condition: Very anæmic—the ears and lips almost bloodless—the tongue red, with streaks of reddish brown in centre; the gums and teeth covered with a thick sordes scarcely removable. Temperature 102° F.; pulse 120; respiration 25. No movement of bowels since the 10th inst. Patient complained of pain in the epigastric region, running to the back and limbs, worse shortly after meals, and bringing on faintness. Tenderness just above the umbilicus, greatest on deep pressure. Vomitus consisted of clots and some bright arterial blood. She had not eaten any food "to amount to anything" since the 21st.

I placed the patient on her back in bed. She occasionally turned from this position to her right side, but could not lie on her left side, as it increased the pain and vomiting.

A mustard plaster was applied to the epigastric region, and small pieces of ice were given at short intervals, with one eighth of a grain of sulphate of morphine hypodermically as required. At 4 and 8 P. M. twenty grains of bismuth subnitrate were administered. The bowels moved at 9 P. M. after an enema. The patient slept but little during the night, vomiting every half hour or so, and dozed between 3.15 and 3.50 A. M.

November 26th, 6 A. M., the bowels moved with blood-stained fæces—melæna. At 7.30 A. M. I gave small doses of carbolic acid and tincture of chloride of iron. This relieved vomiting for an hour. As a repetition of this dose did no good, I gave no more. Nourishment by rectal alimentation, giving every five or six hours from three to four ounces of defibrinized blood containing one grain of chloral to the ounce, and occasionally a tablespoonful of iced peptonized milk. During the day the patient dozed off into a restless sleep, being roused every twenty or thirty minutes by vomiting, although I tried to arrest this excessive action by nitrate of silver, bismuth, iodine, and creosote. At 7 P. M. an enema of peptonized milk and beef peptonoid was given. The patient vomited the stomach contents, consisting of blood, bile, and stomach juices. Reaction strongly acid. She complained greatly of "burning pain," which was relieved by a hypodermic injection of morphine. She passed a somewhat better night, sleeping from 7 to 8.30 P. M. just after vomiting six ounces of coagulated blood.

November 27th, 2 A. M., began the administration of one half a grain of powdered opium every three hours, alternately with one drachm of milk of magnesia. At 5 A. M. she vomited three ounces uncolored stomach contents. She slept soundly from 6 till 7.30 A. M. and awoke hungry. No milk had been given all night, but an enema of peptonized milk and beef peptonoid, four ounces, had been administered. After 12 noon, when patient was awake, two teaspoonfuls of crystallized Carlsbad salts were given, which the patient drank eagerly and retained on her stomach. 1 P. M., bright vomitus, neutral reaction. Urine normal. 1.15 P. M., administered a tablespoonful of olive oil, which I repeated every three hours. She slept from 2 to 3 P. M., quietly. At 3 P. M. she vomited a yellowish fluid unmingled with blood. At 7 P. M. the bowels moved freely, having a tarry appearance and containing globules of oil. On account of the patient's calls for food, I gave her teaspoonful doses of peptonized milk, which she threw up in flocculi. Pain was constant, boring and burning in character. 7.30 P. M., temperature normal; pulse 65; respiration 20. Decubitus—changing from back to right side or prone, as lying on the left side brought on hæmatemesis and pain. She vomited only twice during the night, and slept three hours.

November 28th, condition much the same. Vomited twice during the day. Rectal alimentation. Olive oil continued. November 29th, improving. Same treatment; olive oil, with Carlsbad water and milk of magnesia. November 30th, 8 A. M., the patient slept five hours. Temperature, pulse and respiration normal. Bowels moved freely, with normal fæces. Gave beef broth and thin oatmeal gruel. From this time on the symptoms were easily controlled, and patient gradually improved.

The nurse and I adopted as our motto: "Rest for the stomach," which we tried to bear in mind for the next six weeks, which were uneventful. Vegetables, starchy foods, tea, stimulants, etc., were prohibited, while alkaline drinks, olive oil, peptonized milk, beef broth, and gruels, were given with tonics, chiefly iron in the form of the peptonate. There was another thing to bear in mind. The patient was pregnant, and needed all the strength and tone she could gain both for her own sake and for that of her child. So we encouraged cheerfulness, moderate exercise, and all the out-of-door life we could secure for the patient at this season. In this way, she was brought to child-bed in a fair physical condition. During her labor, in which I attended her, she had one attack of hæmatemesis, but this was the last. There were other complications, which, however, constitute "another story."

CASE II.—May 17, 1895. Miss C., aged thirty-two years, nurse, unmarried.

History.—Anæmic and neurotic. Has had amenorrhœa ever since she began to menstruate at the age of fourteen. For four or five years she has had digestive troubles, epigastric pain after eating, flatulence, and, in the last year especially, eructations. No nausea or vomiting. Has always "dieted," living a vegetarian life. Is of constipated habit. She often felt as if she had a "lump of lead" in her stomach. No history of long or severe illness. While attending a case on May 17th she was taken suddenly with agonizing pain in the epigastric and right hypochondriac regions, running to the shoulder.

Thirst excessive. At 4.30 P. M. Dr. J., the family physician, came to see the patient, and left an anodyne. At 7 P. M. the bowels moved slightly, but there was no relief from pain. May 18th, in the morning, the physician called and took the patient to her own home in his buggy. Gastralgia was severe, but paroxysmal in character. The patient complained of a hard, burning pain in the right shoulder, and of occasional sharp pain over region of liver. No movement of bowels. The doctor examined the patient, and left some medicine for neuralgia, with orders for a milk diet.

May 19th, the doctor came at 11 A. M. and found the patient suffering from severe pain in the epigastric region, the umbilicus, in the right shoulder, and slight pain in the head. He gave some neuralgia powders and sulphate of magnesium. At 5 P. M. the patient and parents requested the physician to call me in consultation.

At 6 P. M. Dr. J. called at my office and asked me to see the patient; he did not consider the case sufficiently serious for consultation. He told me that the patient was nervous and hysterical; that she imagined her extremities were growing cold, and so on. He believed that it was nothing but neuralgia, and he did not want to put the family to any useless expense. He suggested a possibility of intestinal obstruction, but he hardly thought so, as there was no fever, vomiting, or other alarming symptoms. If the patient asked why he had not come, I might tell her that he did not think it was necessary.

Considering the neurotic condition of the patient, the history of trivial gastric disturbances, the sudden shifting pains, and the alarm of the patient, Dr. J.'s diagnosis is not surprising. As Cruveilhier's "dorsal pain" and the epigastric distress came in paroxysmal alternations, it would be easy to diagnosticate neuralgia, especially in this case, where the usual text-book points of diagnosis from cardialgia were absent. There was no particular increase of pain after eating, no relief of pain by epigastric pressure, no history of diagnostic symptoms such as hæmatemesis, vomiting, gnawing pain, or localized tenderness. I reached the house at 7 P. M. and found the patient cyanotic, temperature 97° F., pulse 130, respiration 30. There was little pain, but great uneasiness in the right hypochondriac region. Abdomen very tympanitic, with a decided bulging in the right hypochondriac region, including the umbilicus. Respiratory movements restricted on right side. The area of hepatic dulness was marked in an upward direction, and limited to the enlargement. The patient had noticed the swelling herself, and feared peritonitis. She had vomited in the morning about two ounces of brownish, grumous blood. I made a diagnosis of abscess of the liver with localized peritonitis. Although the patient wished me to stay, I saw that she was sinking fast, and hastened to report to Dr. J., advising him to go to the patient's bedside at once.

May 20, 9 A. M., the patient was in partial collapse; the abdomen greatly distended. She vomited every few minutes until 12 noon. Death occurred at 3 P. M. from shock.

Autopsy.—On the anterior wall of the pyloric portion of the stomach a perforation of about the size of a quarter of a dollar; a sinuous, terraced, round ulcer, the floor being formed by the left lobe of the liver, where there were partial adhesions and abundant pus, showing the recent formation of the abscess. There was a localized area of inflammation which had given rise to the symptoms of peritonitis. I firmly believe that the patient could have been saved by a timely operation.

Therapeutical Notes.

The Absorption of Iron from the Jejunum.—Cloetta, of Zürich (*Archiv für experimentelle Pathologie und Pharmakologie*, xlv, 5, 6; *Berliner klinische Wochenschrift*, December 3d), disputes Quincke and Hochhaus's dictum that iron is absorbed only from the duodenum. He administered it to mice that had been deprived of ferruginous food for two weeks. On killing them, he found the reaction of iron over a considerable portion of the epithelium of the upper part of the jejunum.

The Treatment of Nasal Hæmorrhage. Especially after Removal of Adenoids.—The *St. Paul Medical Journal* for November, citing the *Bulletin de laryngologie, d'otologie, et de rhinologie*, gives the following on the authority of Dr. P. Chevallier:

As regards treatment, all those measures calculated to control hæmorrhage in general are of service. Injections of gelatinized serum are highly recommended. This is prepared as follows:

℞ Chloride of sodium. 105 grains;
Distilled water. 1 quart.

M. To this solution is added gelatin in the proportion of from 5 to 10 parts to the hundred. The whole is then twice sterilized at 100° C., and is then ready for use. It is solid when cold, and is warmed in a water bath when it is to be used.

Another remedy is the solution of peroxide of hydrogen, which is to be painted over the bleeding surface by means of a cotton tampon held in a curved forceps.

An astringent powder which is recommended is composed as follows:

℞ Boric acid, } of each. 75 grains;
Powdered sugar, }
Antipyrine. from 7½ to 15 "
Tannin. 15 "

M.

If the hæmorrhage continues, in spite of all remedies, we must first satisfy ourselves that no tags and shreds of membrane are left hanging, for they often give rise to bleeding. The only way to ascertain this, as a general rule, is by palpation. And, finally, resort must be had to anterior and posterior plugging. The posterior plugs should be large enough to fill the vault and exercise compression on the denuded surface.

The Use of Garlic in Pulmonary Tuberculosis.—Dr. Giulio Cavazzani (*Policlinico*, 1900, p. 724) reports a series of experiments conducted in the city hospital of Venice with reference to the action of garlic in consumption. Garlic is cut into small pieces and dried for a short time. It is given in this form to the patients in quantities of from four to six grammes in twenty-four hours, in fractional doses and in various ways, in order to combat the distaste that most patients manifest for the drug. Over two hundred patients were thus treated, and in addition to the garlic the patients were given the ordinary hygienic and symptomatic treatment. An improvement is said to have taken place in all stages of tuberculosis, especially in the early cases. The sputum becomes mucous in character, the number of bacilli diminishes, until it completely disappears, the cough is lessened, the local physical signs disappear, as do the night sweats and the hæmoptyses, and there is a marked improvement in the appetite and the general condition.

THE NEW YORK MEDICAL JOURNAL,
62-68 West Broadway.

NEW YORK, SATURDAY, JANUARY 19, 1901.

THE HOSPITAL AND THE COMMUNITY.

THERE is good evidence that hospitals are not now held in quite such low esteem by the poor as they were a few years ago. Perhaps the advent of the trained nurse has had much to do with the change. Still more might be accomplished in the direction of hallowing the hospitals in the hearts of the people, we think, if the governing boards, instead of contenting themselves with a dimly formal annual business meeting and a dry printed report, would bring the community into close contact with the institutions now and then. This is done by St. Luke's Hospital, of South Bethlehem, Pennsylvania, which annually, on St. Luke's day, holds a festival, so to speak, one of the main features of which is an address by some medical man; possibly it is done by a few other hospitals. We are led to make this remark by a perusal of a very interesting address delivered by Dr. William Osler, of Baltimore, some weeks ago, on the occasion of the semi-centenary of the Troy Hospital, published in the January number of the *Albany Medical Annals*.

Dr. Osler properly deprecates the bestowal of denominational names on hospitals. He admits, as we all admit, that in hospitals so named much indiscriminate charity is practised, but he thinks that a natural preference must be given in them to sufferers who are "of the household faith." As to wealthy contributors to hospitals' funds, they should take a closer interest in the affairs of those institutions, Dr. Osler intimates, than is manifested by mere gifts of money, and in this he is undoubtedly correct. Those who feel commiseration for the inmates of hospitals, but are unable to give money for their relief, may at least send flowers or read or sing to the sufferers, and those who are able to contribute to the funds might perform these little acts of sympathy in addition. However, it is not everybody who can read or

sing to the sick acceptably or show good taste in floral gifts; so perhaps we should not expect more from the ordinary man of wealth than the commodity for which he has the greatest respect.

Much has been said in recent years about the abuse of medical charity. Dr. Osler deprecates lavish and indiscriminate charity, but he adds:

"The question arises, Who is a deserving person? We are all agreed upon the poor man, but how about the relatively poor, the clerk or mechanic with a large family? Many conditions arise in which he is a worthy recipient of hospital aid. A daughter with typhoid fever, or a boy with hip-joint disease, is much better off in the wards of a hospital than at home, and it is a good deal better for the profession that the father of the family should pay the hospital two or three dollars a week for the care of his child than that he should take food from the mouths of his little ones to pay a doctor's bill, which at the best could not be in any degree adequate to the services rendered. Take the cases, too, which need special services—the obscure skin diseases, obstinate affections of the nervous system, cases requiring delicate operations; a majority of these have already paid a general practitioner a fair fee before applying to hospital. Instead of saying that our charities are abused by such people, I maintain that they are not used enough, and are not sufficiently taken advantage of by the general practitioners. The golden rule in the practice of medicine makes the interest of the patient the first consideration, and so soon as the physician is puzzled, or finds the case to be obscure or not progressing well, instead of straining a family in straitened circumstances—distraining, I would call it—by a consultant's fee, he should send the patient to a hospital. If the patient can pay something for the accommodation, well and good, if not, well and good; to help such is the truest form of charity. I am not speaking, remember, of the absolutely poor, but of the relatively poor and the improvident, upon whom sickness comes as a terrible trial. In relieving these people of their obligations to the profession by placing them in more skilful hands or where the nursing is better the physician only does his duty, though it may be at a pecuniary loss."

It takes courage to set forth such views, and it requires extraordinary conscientiousness in the struggling practitioner to conform to them. It must be admitted, nevertheless, that they are well founded. The pity is that some means cannot be devised of maintaining one's income while one carries out this altruistic course.

CANADIAN MEDICINE.

THERE have recently come to our attention two noteworthy Canadian contributions to the chain of historical sketches that is now being forged to formulate and hand down to posterity an adequate conception of what was accomplished in medicine during the nineteenth century. One of them is the presidential address delivered before the American Public Health Association at its Indianapolis meeting by the eminent Toronto sanitarian, Dr. Peter H. Bryce, reprinted from the *Canadian Journal of Medicine and Surgery*, dealing with the progress of sanitation during the century. It is a masterly and most interesting narrative. It is evident that Dr. Bryce did not set out to magnify Canadian sanitary work—indeed, he expressly says that, so far as he is aware, in no country does there exist to-day a more complete sanitary organization, one in which the legislative, administrative, and scientific functions are better coordinated or more efficiently carried out, than in Mexico—but it appears also from his address that our Canadian brethren were early imbued with the necessity of systematic work for the preservation of the public health, and that their efforts to promote and perfect such work have been constant, energetic, and well directed.

The other contribution is a Retrospect of Medicine during the Nineteenth Century, the leading editorial in the January number of the same journal, signed with the initials of the editor, Dr. Cassidy. The article is well illustrated with cuts from Dr. Henry Smith Williams's *Story of Nineteenth-Century Science* (Harper & Brothers), including a scene in the Necker Hospital, Paris, showing Laennec employing the stethoscope, together with portraits of William T. G. Morton, Crawford W. Long, Theodor Schwann, Louis Pasteur, Rudolf Virchow, and Lord Lister. Dr. Cassidy passes in critical review not only the leading medical events of the century, but also—and without this the mere recital would be almost meaningless—the doctrines and theories that have passed and those that have come. "In concluding this sketch," says Dr. Cassidy, "a regret will intrude that Canada has not carved a name among the medical discoverers of the nineteenth century, though we must congratulate our confrères on the fact that they keep well to the front in scientific knowledge, which they cull with avidity both at home and abroad."

Canadian medicine has indeed much to be proud of. It is not given to every country to produce in each century some eminent discoverer or a man of transcendent genius; that is not necessary to entitle a people to the

credit of doing its part in keeping in motion the machinery that leads to great discoveries. Canada has certainly done her share in promoting the conditions from which discoveries take their origin. Her medical schools, her hospitals, her laws governing the practice of medicine, her cultivation of sanitary science, and her steadfast devotion to progress in medicine, as shown by her excellent periodicals and by the good work of her societies, are unsurpassed. Profitable would it be to us of the United States, a country fifteen times as populous as Canada, if more of us visited our provincial neighbor in quest of professional communion rather than with aims symbolized by rod and gun. It is of the greatest mutual advantage that most of our national special societies admit Canadian physicians to membership, and we hope that the American Medical Association will soon open its doors to our Canadian brethren; the boon would not be altogether to them, for the movement would react to our own good.

 THE PROPOSED NATIONAL PSYCHOPHYSICAL LABORATORY.

WE understand that Congress has under consideration the establishment of a psychophysical laboratory in the Department of the Interior. The purpose of the laboratory is the prosecution of exact studies of the criminal, pauper, and defective classes of our population, such studies as Mr. Arthur MacDonald has carried on in Washington for some time past. Mr. MacDonald's work has received from all quarters of the world such recognition of the value of his labors as must be very gratifying to him. As he would undoubtedly be put in charge of the laboratory, its establishment would insure a continuance and extension of precise researches into subjects that closely concern mankind in general. Our population, by reason of its complex composition, has been thought to be particularly promising of tangible if not decisive results in furnishing material for aiding to reduce to a science the observations that have heretofore been made as to the relations between the bodily and mental make-up of human beings and their course of life, whether creditable, obstructive, or distinctly criminal.

To establish a huge mass of facts and to detect their connection with other facts are tasks that lie at the very foundation of every science. No more complicated science, none fraught with greater difficulties, we may conceive, exists, either *in esse* or *in posse*, than that of the relations between a man's original physical and mental attributes, his constitution, as it is commonly called, and his proneness to a particular form of departure from

either bodily, mental, or spiritual health. If we are ever to meet with noticeable success in overcoming innate tendencies to morbid or perverted states of body, mind, or moral sense, we must begin with just such observations, and that, too, on a large scale, as would be the outcome of a well-conducted bureau such as the proposed psychophysical laboratory in Washington seems intended to become. It appears that the expense is estimated as coming within a very moderate sum, and we know of no reason why the government should not appropriate that amount or even much more to achieve results that are most promising.

THE HEALTH OF HAVANA.

IN a report to the adjutant-general of the Department of Cuba dated January 5th, Major and Surgeon W. C. Gorgas, of the army, chief sanitary officer, quite pardonably calls attention to the improved sanitary condition of the city during the American occupation, and especially to the small number of deaths, 485, in the month of December, 1900, the smallest for that month since the year 1890. Yellow fever, he adds, is diminishing satisfactorily, and the little of it that there is, is seen almost entirely among the Spanish immigrants. Immigration still continues large; in December 4,206 immigrants arrived.

THE AMERICAN DRUGGIST.

THE first number of the *American Druggist and Pharmaceutical Record* for the new century comes to us in a new dress of type, with a vastly improved typographical arrangement, the matter being printed in two instead of three columns to the page as heretofore. Several new departments also appear in this number which are likely to add to the interest and value of the publication to its readers. One of these which will prove of great value to physicians and teachers who are at all interested in pharmacy is a review of current pharmaceutical literature, entitled *Cream of Current Literature*, after the manner of the *conspectus* of our contemporaries' original articles which we publish under the heading of *Pith of Current Literature*. The *American Druggist's* improvement reminds us of the general advance in the periodical literature of pharmacy that has been noticeable for several years past.

THE ACTION OF THE SUPRARENAL CAPSULE ON THE HEART.

DR. SAMUEL FLOERSHEIM, whose article entitled *The Use of the Suprarenal Capsule in Diseases of the Heart* appeared in our issue for October 6th, writes to us that he is preparing another paper on the subject, and would be glad to receive from our readers reports of their observations as follows: 1. The condition of the heart and pulse. 2. The effect on the heart and pulse within ten minutes after the suprarenal powder, three grains, is chewed and swallowed without water.

A MEDICAL JOURNAL'S SEMI-CENTENARY.

WE felicitate our Vienna contemporary, the *Wiener medicinische Wochenschrift*, on the completion of the first half-century of its career and on its method of celebrating the event. Its entire issue for December 29th is devoted to an address to its readers and friends, to a brief history of its career, to reduced reproductions of the pages of its first number, and to a collection of aphorisms with their authors' signatures. The aphorisms have a cover of their own; its first page is taken up with a handsome allegorical design, and on its last page are portraits of Dr. Wittelshöfer, the first editor, and Dr. Adler, the present editor.

A NEW JOURNAL IN NEW YORK.

WE have received the first number, dated January, 1901, of the *New York State Journal of Medicine*, a monthly of twenty-four large double-columned pages of reading matter. It is published by the New York State Medical Association, and is to supersede the association's annual volume of *Transactions*. We do not see the editor's name mentioned. The new journal is of handsome appearance, and the contents of the first number, including four original articles, are of an interesting character.

PENNY LUNCH ROOMS.

OUR attention has been called to the fact, in reference to a minor editorial in our issue for January 5th, that the St. Andrew's coffee stands in New York and Brooklyn to some extent cover similar lines to those commended by us as existing in Chicago. A stall, however, is not a comfortable room where the poor man can obtain some sense of warmth, light, and comfort, to contrast with the gloom of the struggle for life of those whose lot is cast in dark places. Doubtless a wider knowledge of the efforts of the St. Andrew's stands would result in their support to an extent adequate to enabling the institution to make more extensive efforts than hitherto. The suggestion that we have made as to the sale of tickets is, we find, in operation with these stands; the charitable-minded of limited means, therefore, can, by supporting them, not only give a reasonable exercise to the highest faculty of humanity from an individual point of view, but by so doing help the society to attain the extension so much to be desired.

THE PHYSICIAN IN GENERAL LITERATURE.

THE numerous friends of Dr. Lydston, of Chicago, have a fresh opportunity of enjoying the product of his skill as a writer in the shape of a volume recently issued.* It treats of his observations and experiences in a journey across the Isthmus of Panama. The illustrations, for the most part decidedly unconventional, are very interesting, but one of them is so ghastly that it may shock many a reader, as it shows the dangling bodies of four men hanged by a vigilance committee in Lower California.

**Panama and the Sierras; A Doctor's Wander Days.* By G. Frank Lydston, M. D. Illustrated from the author's original photographs. Chicago: The Riverton Press, 1900.

News Items.

Society Meetings for the Coming Week:

MONDAY, January 21st: New York Academy of Medicine (Section in Ophthalmology and Otology); New York County Medical Association; Hartford, Connecticut, Medical Society; Chicago Medical Society.

TUESDAY, January 22d: New York Dermatological Society (private); Metropolitan Medical Society, New York (private); Buffalo Academy of Medicine (Section in Obstetrics and Gynecology); Medical Society of the State of New York; Medical Society of the County of Putnam, N. Y. (quarterly); Richmond, Virginia, Academy of Medicine and Surgery.

WEDNESDAY, January 23d: New York Academy of Medicine (Section in Laryngology and Rhinology); New York Pathological Society; New York Surgical Society; American Microscopical Society of the City of New York; Philadelphia County Medical Society.

THURSDAY, January 24th: New York Academy of Medicine (Section in Obstetrics and Gynecology); New York Orthopaedic Society; Brooklyn Pathological Society; Brooklyn Society for Neurology; Roxbury, Massachusetts, Society for Medical Improvement (private); Pathological Society of Philadelphia.

FRIDAY, January 25th: New York Clinical Society (private); New York Society of German Physicians; Yorkville Medical Association, New York (private); Philadelphia Clinical Society; Philadelphia Laryngological Society.

SATURDAY, January 26th: New York Medical and Surgical Society (private).

Army Intelligence:

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from December 29, 1900, to January 12, 1901:

GREENLEAF, CHARLES R., Colonel and Assistant Surgeon-General, will proceed to Hong Kong, China, for the purpose of inspecting certain vessels at that point, offered for sale, with a view to the purchase of a suitable one for a hospital ship. During the temporary absence of Colonel Greenleaf, Major Louis M. Maus, Surgeon, United States Army, will take charge of the office of the chief surgeon of the division.

REYNOLDS, FREDERICK P., Major and Surgeon, United States Volunteers, is granted leave of absence for two months on account of sickness.

SIMPSON, MAXWELL S., Captain and Assistant Surgeon, Squadron Philippine Cavalry, will proceed from Manila to San Francisco, with a view to discharge.

TESSON, LOUIS S., Major and Surgeon, United States Army, will proceed to Portland, Oregon, and make a thorough sanitary inspection of the transport *Thyra*, now in that port.

WEBBER, HENRY A., First Lieutenant and Assistant Surgeon, will proceed to the Philippine Islands on the transport *Wright*, and is detailed for duty as acting assistant surgeon on that transport.

Naval Intelligence:

Official List of Changes in the Medical Corps of the United States Navy for the two weeks ending January 12, 1901:

ANDERSON, F., Surgeon. Ordered to await orders when recruiting duty is completed.

DENNIS, J. B., Assistant Surgeon. Ordered to the Naval Academy.

DIEHL, O., Surgeon. Detached from the *Lancaster* and ordered home to await orders.

LOWNDES, G. H. T., Surgeon. Detached from the Naval Academy and ordered to the *Lancaster*.

WARD, B. R., Passed Assistant Surgeon, Detached from the Naval Hospital, Mare Island, California, and ordered to the Boston Navy Yard.

Marine-Hospital Service:

Official List of the Changes of Station and Duties of Commissioned and Non-commissioned Officers of the United States Marine-Hospital Service for the Seven Days ending January 10, 1901:

ANDERSON, J. F., Assistant Surgeon. Having been assigned to duty in the Immigration Service at Liverpool, Eng-

land, he is relieved from duty in United States Consulate at that port.

DECKER, C. E., Assistant Surgeon. Granted seven days' extension of sick leave from January 4th.

NYDEGGER, J. A., Passed Assistant Surgeon. To proceed to Chicago and report to the medical officer in command for duty and assignment to quarters.

STIMPSON, W. G., Passed Assistant Surgeon. To proceed to Cripple Creek, Colorado, for special temporary duty.

WALKLEY, W. S., Acting Assistant Surgeon. Granted leave of absence for three days.

WASDIN, EUGENE, Surgeon. Granted leave of absence for fifteen days from January 14th.

WERTENBAKER, C. P., Passed Assistant Surgeon. To proceed to Fontainebleau, Mississippi, for special temporary duty.

Marine-Hospital Service Health Reports:

The following cases of small-pox, yellow fever, cholera, and plague, were reported to the surgeon-general during the week ending January 11, 1901:

Small-pox—United States.

Girard, Alabama.....	Dec. 31.....	Reported present.	
Phoenix, Alabama.....	Dec. 31.....	Reported present.	
Washington, District of Columbia.....	Dec. 29-Jan. 5...	6 cases.	
Jacksonville, Florida.....	Dec. 29-Jan. 5...	1 case.	
West Tampa, Florida.....	Dec. 29-Jan. 5...	2 cases.	
Columbus, Georgia.....	Dec. 31.....	Reported present.	
Wichita, Kansas.....	Dec. 29-Jan. 5...	12 cases.	
Lexington, Kentucky.....	Dec. 29-Jan. 7...	2 cases.	
Shreveport, Louisiana.....	Jan. 2.....	2 cases.	
Baltimore, Maryland.....	Dec. 29-Jan. 5...	1 case.	
Minneapolis, Minnesota.....	Dec. 22-29.....	3 cases.	
Omaha, Nebraska.....	Dec. 22-29.....	6 cases.	
Manchester, New Hampshire.....	Dec. 29-Jan. 5...	18 cases.	
New York, New York.....	Dec. 29-Jan. 5...	13 cases.	
Caswell County, North Carolina.....	Dec. 1-31.....	77 cases.	
Ashtabula, Ohio.....	Dec. 29-Jan. 5...	1 case.	
Cincinnati, Ohio.....	Jan. 4.....	1 case.	
Cleveland, Ohio.....	Dec. 29-Jan. 5...	39 cases.	1 death.
Portsmouth, Ohio.....	Jan. 5.....	3 cases.	
Allegheny City, Pennsylvania.....	Jan. 7.....	1 case.	
Pittsburgh, Pennsylvania.....	Dec. 29-Jan. 5...	11 cases.	
Greenville, South Carolina.....	Dec. 29.....	1 case.	
Memphis, Tennessee.....	Dec. 29-Jan. 5...	2 cases.	
Salt Lake City, Utah.....	Dec. 29-Jan. 5...	34 cases.	
Tacoma, Washington.....	Dec. 29.....	1 case.	

Small-pox—Foreign.

Prague, Austria.....	Dec. 8-15.....	22 cases.	
Nanaimo, British Columbia.....	Dec. 15-21.....	5 cases.	
Vancouver, British Columbia.....	Dec. 1-31.....	2 cases.	
London, England.....	Dec. 15-22.....	1 case.	
West Hartlepool, England.....	Dec. 9-15.....	1 case.	
Paris, France.....	Dec. 15-22.....		8 deaths.
Bombay, India.....	Nov. 21-Dec. 4..		1 death.
Calcutta, India.....	Nov. 24-Dec. 1..		7 deaths.
Madras, India.....	Nov. 23-30.....		1 death.
Moscow, Russia.....	Dec. 29-Jan. 5...	6 cases.	1 death.
Odessa, Russia.....	Dec. 8-15.....	41 cases.	10 deaths.
Glasgow, Scotland.....	Dec. 15-22.....	72 cases.	1 death.
Montevideo, Uruguay.....	Dec. 1.....	1 case.	

Yellow Fever.

Cartagena, Colombia.....	Dec. 17.....		1 death.
Cienfuegos, Cuba.....	Jan. 8.....		1 death.
Matanzas, Cuba.....	Jan. 3.....	1 case.	
Vera Cruz, Mexico.....	Dec. 22-29.....		5 deaths.

Cholera.

Bombay, India.....	Dec. 4.....		10 deaths.
Calcutta, India.....	Dec. 1.....		33 deaths.
Madras, India.....	Nov. 30.....		3 deaths.
Singapore, Straits Settlements.....	Nov. 17-24.....		64 deaths.

Plague.

Hong Kong, China.....	Nov. 25.....		1 death.
Bombay, India.....	Dec. 4.....		70 deaths.
Calcutta, India.....	Dec. 1.....		23 deaths.
Osaka, Japan.....	Dec. 4-13.....	3 cases.	
Wakayama Ken, Japan.....	Dec. 4-13.....	5 cases.	
Yuasa, Japan.....	Dec. 4-13.....		Plague reported.

The Woman's Hospital in the State of New York.

We learn that Dr. P. F. Chambers has been appointed an attending surgeon, to succeed Dr. Thomas Addis Emmet, who has resigned.

The First Russian Congress of Surgeons was held in Moscow on December 27, 1900. The president was Professor Diakonoff.

Dr. Angel Bellinzaghi, whose yellow fever serum is now being tested in the American Hospital in the City of Mexico, is visiting Washington.

The Vital Statistics of Baltimore for the past year show a slight increase in both the birth rate and the death rate in that city over that for the previous years.

The Manhattan Dermatological Society has been organized, with Dr. William S. Gottheil as president, Dr. Ludwig Weiss as vice-president and Dr. Jacob Sobel as secretary.

Philadelphia Medical Club.—Dr. Edward L. Duer has been elected president of the Philadelphia Medical Club to succeed Dr. J. M. Anders, who has resigned the presidency.

An Association of Military Surgeons has been formed among the surgeons of the National Guard of the State of Minnesota, with a view to the improvement of the service.

The Ohio Board of Medical Registration and Examination has elected officers as follows: President, Dr. N. R. Coleman, Columbus; vice-president, Dr. H. E. Beebe, Sidney; secretary, Dr. Frank Winders, Columbus; treasurer, Dr. David Williams, Columbus.

To Prosecute Illegal Practitioners of Medicine.—It is reported that the New York County Medical Society has obtained evidence against a number of unlicensed practitioners, and is about to begin an active campaign against illegal practitioners generally.

The Death Rate in Savannah.—The annual report of the health officer of Savannah, Ga., shows the death rate of that city to have decreased steadily during the past two decades, the rate having been 44.96 per thousand in 1880; 31.37 in 1890, and only 25.90 per thousand in 1900.

The Quarantine Regulations at San Francisco as laid down by Dr. Kinyoun, the Marine-Hospital Service officer in charge at that port, are so stringent as to have evoked a vigorous protest on the part of the local merchants. At least the local newspapers have published numerous sensational articles on the subject.

The Site of the Hospital for Consumptives.—A bill has been introduced in the New York Legislature directing that the new State hospital for consumptives, which the commissioners decided to locate at Raybrook, shall instead be located at Dannemora on State lands, and that the buildings shall be erected by convict labor under the direction of the state superintendent of prisons.

A State Epileptic Colony for Illinois is to come into being, and Northliff, near Elsau, Jersey county, has been conditionally accepted by the State Board of Charities as its future situation. Governor Tanner is reported to have stated on December 5th that there were more than 5,000 epileptics inmates of the various eleemosynary institutions of the State, and they would be transferred to the new institution as soon as it could be completed.

Fined for Illegally Practising Medicine.—Cornelius Edison, of No. 288 Lincoln Avenue, Brooklyn, was recently sentenced in the Court of Special Sessions to pay a fine of \$250 or to spend three months in jail, for practising medicine without a license. He pleaded guilty. The complainants were David Myerle, secretary of the Kings County Medical Society, and Hugh L. Clark, of No. 276 Lincoln Avenue. Edison had treated a member of Clarke's family.

The Grippe.—There is apparently no subsidence of the grippe epidemic, either in New York City or elsewhere. The victims are numbered by the hundreds in every walk of life, and in all the large cities the hospitals are crowded. The record of deaths is comparatively large. In Manhattan borough there have been fifty deaths within the past week, while Brooklyn borough has a record almost as large. Other large cities send in similar reports, some of the most sensational being from Buffalo, Pittsburg, and Chicago, and from Rochester, Washington, D. C., where President McKinley and Admiral Dewey are just recovering from attacks.

Small-pox.—Several more deaths are reported in this city from small-pox, while the epidemic is still prevalent in Milwaukee, Madison, and other Wisconsin cities. Cleveland, Ohio, and several Missouri cities are also suffering, and the legislature of the latter State has voted an appropriation of \$10,000 to the State Board of Health to enable the board to investigate and quarantine small-pox cases.—A Brooklyn magistrate has refused to grant a warrant to arrest Dr. Montague R. Levenson, the physician who had stated that he attended thirty small-pox cases, and reported none.

Medical Legislation at Albany.—Among the measures relating to medicine which have already been introduced in the legislature of the State of New York, now in session, are the following: The charter novum bill, a bill by Mr. Bell aimed at the illegal practices of faith-curists and others, a bill by Mr. Cotton exempting from taxation the property of medical societies in New York City and Buffalo, and a bill protecting practitioners from blackmail and from unjust suits for malpractice.

The Havana Medical Congress.—Plans for the entertainment of the delegates to the third Pan-American Medical Congress, to be held in Havana, Cuba, from February 4th to 6th, inclusive, are being made by a reception committee, of which Dr. A. Glennan, health officer of the port of Havana, is chairman. Governor-General Wood will give a reception to the delegates, probably on the day before the opening of the congress, and he has thrown open to those who cannot afford to stay at the hotels the furnished quarters built for the officials of the Military Hospital. After the scientific sessions on the second day, the evening will be given over to the entertainment of the delegates and their families by the City Council of Havana. It is expected that there will be about 1,500 delegates present, of whom 500 will be Cuban physicians, 300 or 400 Americans, 200 Mexicans and others from the Argentine Republic, Uruguay, Brazil, Venezuela, Colombia, Peru, Chili and other Central and South American countries. The entertainment committee has arranged to give a large ball for the delegates at the Tacon Theatre, an excursion to a sugar plantation, a luncheon at a plantation, an excursion to Matanzas to see the Caves of Bellamar, in the Yunori Valley, a parade of the police and firemen and various other entertainments.

The Court Asked to Compel a Board to Register a Physician.—An alternative writ of mandamus has been granted by Judge Siebecker in the circuit court in the case of the State of Wisconsin *ex rel.* Dr. W. M. Caswell, of Hillsboro, Vernon county, to compel the State board of medical examiners to receive his registration as a practising physician. In his application Dr. Caswell asserts he has been a physician in regular practice for twelve years, and that he made application to the board for registration in the regular way, but his application was refused. The writ is made returnable before Judge Siebecker January 14th.

St. Louis Medical Society of Missouri.—At the last regular meeting, on Saturday evening, the 12th inst., the following papers were read: Excision of the Intact Gasserian Ganglion, with a Report of Two Cases of Trifacial Neuralgia Successfully Treated by this Means, by Dr. Willard Bartlett; A Report of the Microscopic Findings in the above Cases, with a Literature Résumé on the Neuropathology of the Subject, by Dr. Sidney I. Schwab; and the Successful Treatment of Trifacial Neuralgia with and without the Knife, by Dr. C. H. Hughes.

Foreign University News.—The busts of Albrecht v. Graefe and Karl Schweigger were recently unveiled with appropriate ceremonies in the newly erected lecture hall of the ophthalmic clinic at the University of Berlin.—The following have been appointed to the post of *privat-docent* in the University of Berlin: Dermatology, Dr. Karl Gruhns, assistant in the charity clinic for skin diseases; internal medicine and laryngology, Dr. Felix Klemperer, formerly of the University of Strasburg; anatomy, Dr. George Wetzel, assistant in the biological and anatomical institute of the university.—Dr. Von Hippel, director of the ophthalmic clinic at the University of Halle, has been transferred to Göttingen, and Dr. Schmidt Rimpler, of Göttingen, has succeeded him at Halle.—Miss Toni Fellmer has been nominated assistant in the pharmacological institute at Bonn.

The New York Academy of Medicine.—At the last stated meeting, on Thursday, January 17th, the order for the evening was as follows: Presentation of a portrait of Dr. Austin Flint, Sr., by Dr. E. G. Janeway; On the Value of the X-Ray in Medicine, by Dr. F. H. Williams, of Boston; The Value of the X-Ray in Surgery, by Dr. Robert Abbe; The Value of the X-Ray in the Detection and Exclusion of Renal and Ureteral Calculi, by Dr. Charles L. Leonard, of Philadelphia; and The Technique and Correct Interpretation of Radiographs, by Mr. E. W. Caldwell.

At the next meeting of the Section in Ophthalmology, on Monday evening, the 21st inst., the following cases will be reported: A Case of Sudden Total One-Sided Blindness without Ophthalmoscopic Signs, by Dr. T. R. Pooley; and A Case of Abscess of the Brain, Frontal Lobe, with Orbital Cellulitis, by Dr. J. E. Weeks. Dr. Beaman Dougless will read a paper entitled Emphysema of the Upper Lid.

At the next meeting of the Section in Laryngology and Rhinology, on Wednesday evening, the 23d inst., the following papers will be read: Nasal Suppuration, by Dr. Z. L. Leonard; and A Remarkable Case of Glossopharyngolabial Paralysis, by Dr. Wolff Freudenthal. Cases will be presented and new instruments will be exhibited.

The National Jewish Hospital.—The medical and surgical staff for the new year of the National Jewish

Hospital for Consumptives, Denver, Col., have been appointed: Medical advisory board—Dr. John Elsner, Dr. Saling Simon and Dr. Robert Levy. Medicine—Dr. C. B. Van Zant, Dr. H. B. Whitney, Dr. S. Simon, Dr. S. T. Jarecki, Dr. William N. Beggs, Dr. A. Zederbaum, Dr. M. Kleiner, Dr. John Elsner and Dr. H. W. McLauthlin. Surgery—Dr. Leonard Freeman, Dr. Clayton Parkhill, Dr. John Boyce and Dr. William B. Craig. Gynecology—Dr. H. G. Wetherell, Dr. Thomas H. Hawkins, Dr. C. K. Flemming. Obstetrics—Dr. Minnie C. T. Love and Dr. T. Mitchell Burns. Rhinology and laryngology—Dr. Robert Levy, Dr. Henry H. Howland and Dr. Lenora Benton Hamly. Ophthalmology and otology—Dr. D. H. Coover, Dr. W. C. Bane and Dr. Melville Black. Neurology—Dr. B. Oettinger and Dr. W. J. Rothwell. Bacteriology and pathology—Dr. Philip Hillkowitz. Dermatology—Dr. James M. Blain. Dentistry—George J. Hartung.

Hospital Staff Changes.—Dr. McCluney Radcliffe has been elected surgeon of the Wills' Eye Hospital, Philadelphia, *vice* Dr. John W. Croskey, resigned. The resignation is dated December 31st, last. Dr. Croskey is alleged to have taken into his private practice patients who went to the hospital for treatment. When charges were made against him he prepared an answer containing affidavits from several patients showing that they applied to him of their own will. Dr. Croskey had been connected with the Wills' Hospital for twelve years as assistant, and since April 13, 1897, as attending surgeon, succeeding the late Dr. Peter D. Keyser. Dr. Radcliffe has been assistant surgeon to Dr. George C. Harlan, at the Wills' Hospital, for seventeen years.—Dr. Austin Flint, Jr., and Dr. Edward E. Ayres have resigned from the Mothers and Babies' Hospital, New York.—Dr. Arthur P. Powelson has tendered his resignation as assistant physician of the State hospital for the insane at Middletown, N. Y., to take effect February 15th. He has accepted the position of resident physician at the Homœopathic General Hospital in Rochester.

Hospital Buildings and Endowments.—The site for the New York State Tuberculosis Hospital has been located at Raybrook, Franklin County, N. Y., about four miles east of Saranac Lake. The legislature will be asked to appropriate \$100,000 for the erection of the first pavilions for the hospital. Plans for the institution are being prepared by State architect Heins.—The sum of \$16,000 has been subscribed by a number of wealthy residents of Plainfield, N. J., toward the fund of \$30,000 which is required to establish the Muhlenberg Hospital in that city.—A fund is being raised by residents of Bath Beach, N. Y., for the establishment of an emergency hospital. That district of Brooklyn is practically without ambulance service, as it requires almost two hours to receive assistance from the nearest hospitals.—Bids for the construction of a barracks, hospital and crematory at Marcus Hook, Philadelphia, have been called for by the State Quarantine Board of Pennsylvania. The new buildings are to be used for the isolation of persons afflicted with contagious diseases, and accommodation for more than 600 patients will be provided.—The Central State Hospital at Petersburg, Va., which has been in course of erection, was opened to the public early this month. The building accommodates 160 patients.—A bill has been introduced in Congress permitting the directors of Providence Hospital, Washington, to increase the accommodations at that institution.—The Trades' Council, representing nearly all of the trade or-

ganizations of Bridgeton, N. J., proposes that each mechanic, clerk, and employee of every kind affiliated with the organization, donate half a day's pay to the Bridgeton Hospital. It is expected that \$10,000 will be realized.—The Pennsylvania Legislature has been asked for an appropriation of \$60,000 for improvements in the Allegheny General Hospital.—The new Gouverneur Hospital, New York City, was formally opened on January 5th. The new building has accommodations for 115 patients.—The sum of \$40,000 has been collected and \$9,000 additional has been subscribed toward the erection of a new Jewish hospital building at Jefferson and Cherry streets, New York City. Beth Israel Hospital Association has the matter in hand, and proposes to expend \$75,000 for the ground and \$115,250 for the structure to be erected on it.—The Lowell General Hospital has received a legacy of \$5,000 from the late Julia A. Simpson. A new building is to be erected, the site having already been secured.—The Presbyterian Hospital and St. Luke's Hospital, New York City, have each received a legacy of \$59,140 from the estate of the late James D. Sarven, and the Tarrytown hospital has received \$5,000 from the same source.

Bellevue Hospital Investigation.—The special committees of the Bellevue Hospital Medical Board appointed to aid John W. Keller, Commissioner of Charities, in his investigation of the affairs of the hospital, met recently. It was the understanding previous to the meeting that the committee was to take up the case of Dr. Moore, who had been in charge of the insane pavilion and had been suspended by Mr. Keller, but after the meeting, which lasted nearly three hours, it was said that the case of Dr. Moore had not been discussed. Members of the committee at the meeting were: Dr. Alexander Lambert, Dr. A. A. Smith, Dr. William M. Polk and Dr. George B. Fowler. The Grand Jury is also continuing its investigation into the abuses at Bellevue Hospital. The inquisition will seek for evidence that will fix the responsibility for injuries inflicted upon inmates of the insane pavilion. It was shown by the records of the Ward's Island Asylum that of 700 insane patients received from Bellevue during 1900, 260 were received with scars or wounds. Commissioner Keller holds that this record is not conclusive proof of cruelty at the insane pavilion. John P. Faure, one of the commissioners of charities under Mayor Strong's administration, came to the rescue of Dr. Allen Fitch, examiner in lunacy at the insane pavilion of Bellevue Hospital, who is under charges of having exacted excessive fees for the examination of patients in the insane pavilion who were to be committed to private sanitariums. Mr. Faure called upon Commissioner of Charities Keller and told him that it was by his authority that Dr. Fitch and the other examiner had charged \$50 for examinations under the rule which provided that they should charge not more than \$25. Commissioner Keller has arranged with the State Commission in Lunacy to have the alien and non-resident patients in the insane pavilion taken to Ward's Island and held there in the State Hospital until they can be sent to their homes. The trial of the three nurses, Davis, Dean and Marshall, who are under indictment for manslaughter in the first degree for having caused the death of Louis H. Hilliard in the insane pavilion, begins on January 21st. Dr. John W. Moore resumed duty at the hospital on Wednesday, but no information regarding the charges under which he was suspended has been made public. The committee of the medical board submitted its report on the results of the investigation to the board

on Wednesday, which approved the report and transmitted it to the commissioner. The report embraces recommendations for a set of regulations to govern the institution which will definitely fix the responsibility in each case so that in case of any abuse the proper person can be held to individual responsibility.

Births, Marriages and Deaths.

Married.

DENNIS—WARE.—In Fort Monroe, Virginia, on Monday, January 7th, Dr. Benjamin Dennis, United States Army, and Miss Adelaide Ware.

HAINES—BROWN.—In New York, on Wednesday, January 9th, Dr. William Hoggan Haines, of Pittsburgh, and Miss Harriet Estelle Brown.

KEENAN—CAMPBELL.—In Brooklyn, on Wednesday, January 9th, Dr. Henry C. Keenan and Miss Helen J. Campbell.

KNAPP—SPENGEAN.—In Hackensack, N. J., on Thursday, January 3d, Dr. Louis P. Knapp and Miss E. Spengeman.

LYNCH—HAULENBEEK.—In New York, on Tuesday, January 1st, Dr. Jerome Morley Lynch, of London, England, and Miss Harriet Louise Haulenbeek.

RICH—YELLOTT.—In Towson, Maryland, on Tuesday, January 1st, Dr. Frank Rogers Rich, of Georgetown, District of Columbia, and Miss Frances Louise Yellott.

SMITH—ELLIOTT.—In Towson, Maryland, on Tuesday, January 8th, Dr. Robert Percy Smith, of Sunnybrook, Baltimore County, and Miss Martha B. Elliott.

STEWART—FLETCHER.—In Mount Clemens, Michigan, on Thursday, January 3d, Dr. Duffield Stewart, of Detroit, and Mrs. Katharine Fletcher.

THOMAS—CHADWICK.—In Boston, on Saturday, January 5th, Mr. Douglas H. Thomas, Jr., and Miss Bessie Lyman Chadwick, daughter of Dr. James R. Chadwick.

Died.

BOHANNAN.—In Louisville, Kentucky, on Thursday, January 7th, Dr. Thomas Bohannan, in the eighty-fifth year of his age.

BORDEN.—In Stamford, Connecticut, on Wednesday, January 9th, Dr. Charles B. Borden, in the fiftieth year of his age.

CARR.—In Rochester, on Tuesday, January 8th, Dr. Allen B. Carr, in the forty-eighth year of his age.

CLAUDE.—In Annapolis, Maryland, on Thursday, January 10th, Dr. Abram Claude, aged eighty-two years.

CONNOLLY.—In Baltimore, on Wednesday, January 9th, Dr. Francis Grafton Connolly, in the eighty-first year of his age.

DENNIS.—In Kansas City, Missouri, on Saturday, January 5th, Dr. Robert Dennis, United States Volunteers, in the twenty-fourth year of his age.

DODGE.—In Chicago, on Saturday, January 12th, Dr. William Campbell Dodge, in the fifty-eighth year of his age.

GARVIN.—In New York, on Friday, January 11th, Dr. Joseph A. Garvin, aged twenty-nine years.

HARRIS.—In Washington, on Tuesday, January 8th, Dr. Charles Morris Bainbridge Harris, aged seventy-three years.

JOHNSTON.—In Allegheny, Pennsylvania, on Tuesday, January 1st, Dr. Edward Boggs Johnston, in the thirtieth year of his age.

KRESS.—In Johnstown, N. Y., on Tuesday, January 8th, Dr. E. H. Kress, aged twenty-seven years.

LEE.—In Brooklyn, on Tuesday, January 8th, Dr. Lucius J. W. Lee, in the sixty-fifth year of his age.

PARDEE.—In New York, on Friday, January 11th, Dr. Edward L. Pardee, in the fifty-eighth year of his age.

PORTER.—In Redlands, California, on Sunday, January 6th, Dr. Alexander Shaw Porter, United States Army, retired, formerly of Lonaconing, Maryland, aged thirty-three years.

SMITH.—In Manila, Philippine Islands, on Tuesday, January 8th, Dr. Louis P. Smith, United States Army, in the thirtieth year of his age.

TRUXILLO.—In Assumption Parish, Louisiana, on Monday, January 7th, Dr. Robert A. Truxillo.

WHEELER.—In New York, on Thursday, January 10th, Dr. Thomas Brown Wheeler, of Montreal, aged sixty-five years.

Pith of Current Literature.

Philadelphia Medical Journal, January 12, 1901.

A Case of Urethrorectal Fistula Cured after a Third Operation. By Dr. Orville Horwitz.

Fallacies Concerning the Menopause. By Dr. George Erety Shoemaker.—For a period of twenty-five years in a woman's life, *i. e.*, from thirty-five to sixty years of age, it would seem that the "change of life" is popularly supposed to cover every pelvic or abdominal symptom. The author believes that the prevalent large fatality from cancer is due to this state of affairs, rather than to any other one cause. The menopause is not a disease and is not attended by disease. Owing to the prevalent idea that hæmorrhage is to be expected, excessive flowing is allowed to go on for a very long time without the patient's consulting a physician. Methodical questions on this point will reveal definitely whether the patient is bleeding too much. Another fallacy is that, with fibroid tumors of the uterus which are growing or causing disturbance, the patient will do well to wait for the menopause. With the present low mortality, the question of operative intervention stands on a different basis. The hope that the menopause will cure the disease is in itself fallacious, and the author fails to recall a case of uterine fibroid which gave trouble during menstrual life and subsided after the menopause.

Wound of the Trachea, with Suture and Union by First Intention. By Dr. E. S. Goodhue.

Leukæmia and Splenic Pseudoleukæmia. By Dr. Everett G. Brown.—The author presents two cases of the more common form of leukæmia, known as the splenomyelogenous variety, and a third case of the much rarer and very interesting form of disease known as splenic pseudoleukæmia, or splenic anæmia. In making a diagnosis of *true* leukæmia the blood examination tells everything, while in the *pseudo*-leukæmias it furnishes only negative evidence, for, as yet, we have found no distinctive quantitative or qualitative change in either the white or red cells.

Suggestions on the Treatment of Whooping-cough. By Dr. H. F. Thompson.

Re-expansion of the Uterus in Labor. By Dr. D. Benjamin.—The author has come to the conclusion that the parturient womb during any stage of labor and for a few hours thereafter can be expanded to about the same size as it had when labor began. If this is so, an appreciation of the importance and truth of the foregoing proposition enables us to open a very valuable field of practice, and to introduce a number of exceedingly valuable and important procedures or operations based on it.

The Disinfection of Infected Typhoid Urines. By Dr. Norman B. Gwyn.

Administrative Control of Tuberculosis. By Dr. Collins H. Johnston.—The author has written an interesting and instructive article on this subject. The most important sanitary problem of to-day is that of the prophylaxis of pulmonary tuberculosis. The public should be *educated* and not *alarmed*; and, for the purpose of doing this in a rational way, the State should insist upon the compulsory notification of every case of tuberculosis within its borders.

Medical News, January 12, 1901.

Splenic Anæmia—Anæmia with Enlargement of the Spleen. By Dr. Aloysius O. J. Kelly.—The occurrence

of a symptom-complex, characterized especially by grave and progressive anæmia and enlargement of the spleen, but unassociated with leucocytosis or enlargement of the lymphatic glands, has been recognized for a long time. The author reports a very interesting case in point, singular, however, in that the hæmorrhage was very interesting and from an unusual source—the genitals. The dyspnoea was extreme, and the temperature was very high; usually from 103° F. to 104° F., rarely below 102° F. in the evenings. This disorder generally lasts from six months to two or three years. When there is a slow course, surgical treatment may be undertaken, in properly selected cases, with hope of a successful outcome.

Some Diagnostic Details. By Dr. William Edgar Darnall.—No physician can see too much; observe too carefully. No detail is too trivial. The expression of the face and the quick glance of the eye often speak volumes. The opium fiend, the morphinomaniac, and the alcoholic, betray their weaknesses in their expressions; while the careworn, anxious look of the mother, bearing the burden of domestic duty in spite of ovarian and uterine troubles, is familiar. The tone and expression of the voice are important. This tone language determines, in the infant, whether its cry is the cry of anger, of gripping pain, or the fretting of general discomfort. The complexion should not go unnoticed. The breathing and position of the patient may be indicative, while the odor is prominent in many diseases. A correct appreciation of temperament may be a very valuable thing in treatment as well as in diagnosis. These details will well repay the close and careful observation given to their study.

On Gonorrhœal Cystitis in the Female. By Dr. F. Bierhoff.—If we use the non-irritant, non-astringent antiseptics, we can achieve the best result by beginning our treatment at the earliest possible moment. Besides the restriction of diet and the use of frequent hot sitz baths, we may begin the use of such remedies in the form of urethral and vesical irrigations, some of the solution being allowed to remain in the bladder each time. The author gives five cases.

Severe Acute Pleurisy, Followed by Phlebitis; Death from Embolism. By Dr. Charles Ross Jackson.—This case is interesting because of (1) the amount of fluid removed from the chest, and manifestly due to acute pleurisy, and (2) the development of a phlebitis after simple pleurisy—a rare occurrence. The patient was also suffering from a large intra-abdominal tumor. In the absence of autopsy, its relation to the phlebitis is purely conjectural, though it is probable that, by its size and pressure, it disturbed the circulation in the leg, and thereby aided in the formation of thrombus.

Case of Dextrocardia. By Dr. Homer M. Thomas.—From the history, and the present physical findings, the author believes that the case he reports is a case of acquired dextrocardia, due to fibroid phthisis and an antecedent attack of pleuropericarditis. Treatment is mainly directed toward the maintenance of the best possible physical condition and the relief of acute symptoms as they may arise.

Boston Medical and Surgical Journal, January 10, 1901.

A Short Account of the Recent International Medical Congress in Paris. By Dr. Henry Barton Jacobs.

The Radical Treatment of Lacrymal Diseases. By Dr. Walter B. Lancaster.—The great majority of cases of epiphora are amenable to the usual conservative treatment, which consists in the use of astringent and anti-

septic collyria, syringing and probing, and occasional treatment of the nasal cavities. As to whether the radical operation should consist in removal of the gland or of the sac or of both, the author favors removal of the sac alone, which removal takes away the source of irritation, and not only does away with the disease of the sac and its dangers, but diminishes materially the flow of tears.

An Operation for Cataract. By Dr. Edward L. Parks.

Remarks upon Spinal Cocainization Suggested by Cases Seen at Tuffier's Clinic in Paris, August, 1900. By Dr. Maurice H. Richardson.—The author witnessed two operations. From one patient were removed two large ovarian cysts; from the other was removed a renal tumor which had filled the left side of the abdomen. These operations were admirably borne, and yet the whole impression was distinctly unfavorable to this method of anæsthesia. The patients appeared in actual danger. The facial expression, the pallor, the pulse, were not unlike those of a patient in deep shock. Such an appearance would, perhaps, be expected after the removal of a renal tumor filling one half of the abdomen, however mild and successful the anæsthetic, but it should not be expected after the removal of uncomplicated ovarian cysts under ether anæsthesia. The author concludes that the advantages of spinal over general anæsthesia, however great they may be under certain circumstances, cannot be demonstrated except by years of observation and by thousands of experiments, and he is convinced that this method is not without serious dangers; time alone will show what and how great these dangers are. At present there is danger from the mere puncture, danger of cardiac depression, and danger of sepsis. And consciousness is a disadvantage instead of an advantage.

The Purulent Rhinitis of Children as a Source of Infection in Cervical Adenitis. By Dr. Carolus M. Cobb.—The author asserts that the plan of treatment usually followed in dealing with cervical adenitis is the merest empiricism, and he enters an earnest plea for the treatment of these cases on the same lines that govern the treatment of adenitis in other parts of the body. The source of infection in cervical adenitis is very probably in close proximity to the glands involved, that is, the mouth, throat, nose, or ear. The percentage of cases which are caused by general systemic infection is not so large as is generally supposed.

Journal of the American Medical Association, January 12, 1901.

The Diagnosis and Treatment of the Prebacillary Stage of Pulmonary Tuberculosis. By Dr. J. M. Anders.—The author refers to that variable period, often of long duration, which precedes the presence of tubercle bacilli in the sputum. The most characteristic grouping of physical signs during the first stage—sometimes present prior to the discovery of tubercle bacilli—may be thus summarized: "Lagging," or defective expansion, as noted on inspection and palpation, a localized increase in the tactile fremitus, enfeeblement of the normal vesicular murmur with (at a later period) prolongation and sharpening of the expiration. There is also a clicking râle, which, though less commonly present, is an almost conclusive indication. A preliminary course of gastric antiseptics and stomachics, coupled with an open-air existence little short of injurious exposure, sometimes stimulates the appetite, which is usually poor or even lost, and increases the digestive power. The patient should not be

sent to the seaside during the warm season if cough is present. The author strongly favors a rigid system of feeding, even in the early stages, and he believes that the French method of forced feeding deserves a trial if there is absolute loathing of food. Medicinal agents should be employed in the early stages to increase the bodily resistance by improving the principal nutritive functions. Creosote, in doses that the stomach can tolerate, should be prescribed. Cod-liver oil and the hypophosphites are serviceable in a large proportion of early cases, and the same is true of arsenic, though perhaps in a lesser degree.

The Relative Importance of Valvular and Muscular Lesions in Diseases of the Heart. By Dr. Solomon Solis-Cohen.—As a general rule, the exact site and nature of the valvular lesion are of less importance therapeutically and prognostically than the state of the cardiac muscles. The most important exception to this rule is in the case of excessive mitral stenosis. In many cases in which no evidence of valvular lesion can be detected during life, and in some of which normal valves are demonstrable after death, there exist rational signs of cardiac incompetence which are due to diseases of the cardiac muscle.

A Clinical Study of Myocarditis. By Dr. Louis Fau-gères Bishop.

A Plea for a More Rational Prognosis in Cardiac Affections. By Dr. J. J. Morrissey.—Murmurs do not invariably mean endocarditis; the occupation, environment, and temperament of the patient are essential elements in the prognosis. When some hypertrophy with no complications is found in a young man, it is probably the result of active exercise, and to inform him that he has heart disease would be to excite, in many cases, needless apprehension. Never hesitate to ask a patient to return for further examination.

Treatment of Prostatic Hypertrophy. By Dr. Parker Syms.—After prostatic hypertrophy is established, nothing can afford permanent relief to the patient except some procedure which will remove the obstruction to the outflow of urine, and the author urges the importance of the early recognition of obstructing prostatic hypertrophy, and insists that these patients should be submitted to a radical operation before the cystitis, prolonged pain, infection, and fatigue have put them in a condition where they are unfit to undergo a surgical operation.

Treatment of Tuberculosis of the Knee Joint. By Dr. Wisner R. Townsend.—The author believes that attention to the general health, proper protection and rest to the joint, the intelligent prevention or correction of deformities, aided by proper surgical procedures, when indicated, will prove that tuberculosis of the knee joint is a disease in which surgeons may accomplish much, and the results will fully justify the expenditure of our best thought and time.

The Education of the Sense of Touch in Feeble-minded Children and its Connection with Manual and Industrial Training. By Fletcher Beach, M.B., F.R.C.P.

Euthanasia—A Medico-legal Study. By Louis J. Rosenberg, LL. B., and Dr. N. E. Aronstam.—After a lengthy consideration, the authors arrive at the conclusion that the practice of euthanasia would, in the long run, cause more harm than good. If the physician does his utmost to alleviate pain and to make the pangs of death as void of agony as possible, he will comply with the highest standard of ethics and will earn the gratitude of humanity.

Removal of a Piece of Steel from the Globe by Electromagnet. By Dr. Walter B. Johnson.

Medical Record, January 12, 1901.

Coffee as a Beverage, and its Frequent Deleterious Effects upon the Nervous System: Acute and Chronic Coffee Poisoning. By Dr. William M. Leszynsky.—In roasted coffee are found caffeine and caffeone, the latter consisting of the volatile substances developed in the process of roasting. While the caffeine exerts the larger part of the physiological action of coffee, the cerebral stimulation and activity produced are thought to be largely due to caffeone. The author believes that it is just as necessary to inquire into the patient's habits in regard to coffee, tea, and cocoa as it is to question him as to his use of alcoholic stimulants. Many over-sensitive people complain that a single cup of coffee at once induces in them a transitory sensation of well-being, increased rapidity of thought, etc., which are soon succeeded by a feeling of apprehension, general tremulousness, and indigestion. If a smaller dose were taken, commensurate with their susceptibility, the secondary objectionable symptoms would often fail to appear. The habitual daily indulgence in coffee, even in moderate quantity, by those who are over-sensitive to its action, invariably leads to persistent functional disorder of the nervous system, as well as to disturbance of digestion, which rapidly subsides when the use of coffee is discontinued. Suitable hydiatic treatment and careful attention to the diet and excretions should be systematically carried out. As a sedative to the nervous system, and also to replace the accustomed stimulation, the author prescribes the following:

- R Sodium bromide. 15 grains;
 Fowler's solution of arsenic. 2 minims;
 Compound tincture of gentian. $\frac{1}{2}$ drachm;
 Fluid extract of kola. 15 minims.

M.

To be taken in water three times a day. After five or six weeks this is to be discontinued, and tonic pills containing arsenic, quinine, and strychnine, or some similar combination, should be taken daily for several months.

An Improved Method of Performing Suprapubic Cystotomy. By Dr. C. L. Gibson.—As performed by the author, this operation consists in snugly surrounding a tube of suitable calibre by an inverted cone of bladder wall. The ends of the sutures of the second row are left long, and are carried through the abdominal wall, which is closed snugly by sutures through the musculo-aponeurotic layer, only sufficient space being left for the exit of the tube.

Some Remarks on the Modern Surgical and Medical Treatment of Epilepsy. By Dr. L. Pierce Clark.—Idiopathic epileptics with typical *grand-mal* seizures should never be trephined. Those in whom the seizures are of the Jacksonian type should be trephined only when infantile cerebral palsies can be excluded and when the family and personal degeneracy is at a minimum. Traumatic epileptics may be trephined when the injury is definitely proved, stands in direct causal relation, and has existed not more than two years. As to the medical treatment, associated with diet, regular occupation, and personal hygiene, the bromides give the best results in idiopathic epilepsy. Singly or combined, they still remain our chief sedative for the epileptic state. To be effective in chronic and long-standing cases, the bromides should be given in large daily amounts, from 300 to 400 grains if necessary. Hot and cold baths, high enemata, alimentary antiseptics, and massage are absolutely essential to successful bromide medication. When the bro-

mides are contraindicated or cannot be given in large doses, bromine is a worthy substitute. Salt starvation or semi-salt starvation is a great adjuvant to the bromide treatment.

Report of a Case of Primary Glioma of the Optic Nerve. By Dr. Redmond W. Payne.

The Choice of Suture for the Patella. By Dr. Edwin M. Cox.—The author gives three cases illustrative of his belief that the absorbable suture can be used successfully for holding the fragments of a broken patella, and he asserts that the absorbable suture has many advantages over the metallic. A matter of great importance is the application of the plaster-of-Paris splint during the first few weeks, so that moderate pressure shall be exerted above the patella.

Lancet, January 5, 1901.

Clinical Varieties of Bright's Disease. By Dr. J. R. Bradford.—In classifying Bright's disease clinically, we may recognize three forms, namely, the acute, the chronic, and the latent; understanding by the last, the condition in which, notwithstanding the existence of serious renal disease, symptoms of ill health are either absent or very trivial. In making this classification nephritis must be separated and also granular kidney. Although there is a great resemblance in the ætiology and in the morbid anatomy between acute nephritis and acute Bright's disease, yet there are considerable clinical differences. Dropsy is usually absent in acute nephritis, the symptoms being entirely urinary, and the process being developed early in the course of the primary causative affection (scarlet fever, etc.). The mere occurrence of the secretion of a concentrated urine loaded with albumin, and perhaps containing blood, is insufficient for the diagnosis of acute Bright's disease. The matter may be put in a different way by recognizing two varieties of acute Bright's disease; one with dropsy, and the other without.

At the present day the old view, that chronic Bright's disease was generally the sequel of the acute disorder, is no longer held with the tenacity that it formerly was, and it is generally recognized that a great many cases of chronic Bright's disease, if not the majority, are chronic and insidious from the outset. Clinically, two varieties of the chronic form may be recognized. One is a condition in which the patient suffers from dropsy and passes a scanty and highly albuminous urine loaded with casts. The other variety, which is also exceedingly common, is where the patient presents no signs of dropsy and where, notwithstanding the fact that the urine is highly albuminous, the quantity is not greatly diminished and in some cases is considerably increased. The patient complains either of anæmia and weakness, or of circulatory disturbances due to high tension. There may be great emaciation, and pigmentation of the skin is present in some cases. The first form is due to what is called "large, white kidney"; the second to "contracted white kidney." Most cases of "latent" Bright's disease come under the second head; no serious symptoms of ill health are presented until the onset of uræmia.

Uræmia in one or other of its forms may be met with in any destructive disease of the kidney, but the large proportion of cases are associated with the contracted white kidney. It is here not only remarkable for the suddenness of its onset and the violence of its symptoms, but also for its marked fatality. In acute Bright's disease, on the other hand, uræmia is not nearly so fatal. Chronic Bright's disease may not only be chronic from the outset, but also the two varieties of chronic Bright's

disease are not necessarily different stages in one and the same morbid process, but represent rather the different effects of perhaps the same morbid process.

A Series of Cases of Actinomycosis. By R. J. Godlee, F. R. C. S.—The author reports fifteen cases of actinomycosis illustrating most of the commoner and some of the rarer manifestations of the disease. Of these, ten were in men and five in women. The ages varied from nine to forty-five years. In four cases the lungs and pleura were principally affected; in six cases, the liver and pleura; in two cases, the cæcum or appendix; and the rectum, the jaw and the neck in one case each, respectively. Four of the fifteen patients recovered, though one died subsequently of pulmonary tuberculosis. Vigorous treatment with iodide of potassium was tried in several cases, but to no purpose. The author emphasizes the necessity of vigorous surgical treatment, wherever any chance of success is offered. The special points brought out are the following: (1) The probability that this uncommon disease may be mistaken for others of everyday occurrence; (2) the possibility that for long periods, and even after death, no signs of the ray fungus may be present in the discharges or discoverable in the tissues; (3) the characteristic appearances of the abscesses when opened; (4) the possibility of true embolic pyæmia resulting, the secondary abscesses containing the ray fungus; (5) the fact that if the liver or lungs are affected, lateral curvature of the spine is likely to occur, the concavity being toward the affected side.

The After-results in Forty Consecutive Cases of Vaginal Hysterectomy Performed for Cancer of the Uterus. By Dr. A. H. N. Lewers.—The conclusions that appear to follow from the consideration of the facts in this paper are: (1) That in a certain proportion of cases, patients suffering from cancer of the uterus may be relieved by operation for periods of many years—in some cases for so long a time, seven years and upward, that there seems some probability that the relief may be permanent; (2) that the proportion of cases in which this result can be expected must remain very small so long as patients generally only seek advice at a late stage of the disease; and (3) that consequently the great desideratum is early diagnosis.

Improvement in this direction depends to some extent on the better appreciation on the part of women themselves of the early symptoms of the disease, and especially of the significance of bleeding after the menopause, or the bleeding occurring at an earlier time of life between the menstrual periods. Early diagnosis, of course, also depends partly on the profession. Especially important is the general recognition of the gravity of the symptom just mentioned. It is equally important also to bear in mind that patients suffering from cancer of the uterus may, and generally do for a relatively long period, look quite well. They may be well nourished, or not infrequently even excessively fat; and, as regards the aspect of the case, they may appear to be in perfect health.

A Case of Deformity of the Skull Simulating Leontiasis Ossea, Associated with a Condition of Syringomyelia; No Physical Signs of Syringomyelia Present. By Dr. J. S. Collier.—The author reports a case of this affection occurring in a man aged thirty-eight years, which is of peculiar interest as it exemplifies (1) the presence of syringomyelia in the absence of all the usual signs of that condition, and (2) a close simulation, both in signs and symptoms, of leontiasis ossea by a thin deformed skull and meningeal ossification. The patient was very short in stature, and complained of paralysis of

the right arm, of fits commencing in the right arm, and of gradually increasing deafness. When four years old he fell twenty feet from a window, striking upon his head. The head was much flattened vertically, and was very broad. It was as if the posterior two thirds of the vertex of the skull had been telescoped into the base by pressure from above, leaving a remarkable calvarial fold along the line of bending. The skull was opened over the arm centre, and the meninges found to be ossified in places. The patient died suddenly about three hours after the operation. At the autopsy a cavity was found in the medulla and spinal cord, attaining its maximum size at the fifth cervical segment. The usual signs of syringomyelia were absent, although the examination of sensibility was not sufficiently thorough to exclude absolutely the presence of some sensory change. Deformities of the skull appear to be rare in cases of syringomyelia, and in most of the recorded cases the deformity has approached to the acromegalous type.

Filariasis and its Consequences in Fiji. By M. I. Finucane, M. R. C. S.—The author describes the operation for elephantiasis of the scrotum as usually performed by him at Suva, Fiji, where filariasis is prevalent among natives and Europeans. The disease is seen in its most virulent form in low-lying, swampy districts. In some provinces it is impossible to find an adult person free from the disease. Cutaneous and deep lymphatic varix and orchitis, lymph scrotum, and elephantiasis, are all to be met with in varying stages of the disease. Chyluria is rare in Fiji. Abscess is the commonest form of the disease, with elephantiasis next in frequency. Quinine is given with good effect in acute filarial attacks and at the same time local remedies are employed.

A Case of Mollities Ossium with Spontaneous Fracture through the Great Trochanter of the Left Femur. By Dr. J. H. Ewart.—The special points of interest in the case here reported are: (1) The duration of the disease (fourteen years) with so little discomfort; (2) the small number of bones affected, viz., the left side of the pelvis, both femurs and the tibiæ; and (3) the age of the patient (sixty-five years), and the fact that callus was thrown out and union occurred in nine weeks.

A Case of Cobra-poisoning Treated with Calmette's Antivenine. By W. Hanna, M. B., and G. Lamb, M. B.—The authors report a case of cobra-poisoning successfully treated with Calmette's antivenomous serum. One of them was bitten while extracting poison from a full-sized cobra. Eighteen cubic centimetres of an old, deteriorated, antivenomous serum were at once injected, followed in three hours and a half by ten cubic centimetres of fresh serum. By that time general symptoms of cobra-poisoning had set in, but they passed away in three hours after the second dose of serum.

The following conclusions are drawn: (1) That great care is required in handling poisonous snakes; (2) that the puncture of a fang of a passive snake is not to be neglected, as a considerable quantity of venom may be forced out by reflex action; (3) that thorough sucking of the wound is of little avail, for the poison lies deep; (4) that it is advisable to keep a stock of fresh serum in all dispensaries.

Membranous Oesophagitis. Expulsion of a Complete Cast of the Oesophagus. By Dr. N. Raw.—The author reports a case of this rare and remarkable affection occurring in a man aged forty-six years. He had been a drinker of neat whiskey for several years, which invariably caused a burning sensation in his throat and down the line of his oesophagus. During the last six

months he had had increasing difficulty in swallowing solids, and on admission could only swallow fluids. But he could and did still drink his usual amount of neat whiskey. Six days after admission, after a violent fit of coughing, he vomited a complete cast of his œsophagus, eight inches and a half long. It was foul-smelling and of a dirty greenish appearance. Later, the operation of gastrostomy was performed, and the patient was fed *per rectum*, but he died from asthenia six days later. Microscopical examination showed that the cast was a complete slough of the inner layers of the œsophagus as far as the muscularis externa. This is suggestive of a submucous dissecting cellulitis leading to complete separation of the inner coats of the gullet.

British Medical Journal, January 5, 1901.

Leucocythæmia. By Dr. R. Saundby.—The author's article is based upon the study of six cases of leucocythæmia, admitted to the General Hospital, Birmingham. He reviews our knowledge of the morbid anatomy of the disease, and analyzes the symptoms, paying special attention to the condition of the blood. The treatment should be designed to place the patient under the most favorable hygienic conditions, in a healthy, bracing climate on a dry soil, with good air, good food, and favorable surroundings; and he should, if possible, be free from all sources of worry or mental emotion. The most valuable drug is arsenic, the administration of which should be begun with small doses and gradually increased. Splenectomy is hardly justified from our present pathological standpoint as a rational proceeding; out of twenty-four operations, only one resulted in recovery.

Acute Dilatation of the Heart in Diphtheria, Influenza, and Rheumatic Fever. By Dr. D. B. Lees.—In fatal cases of diphtheria the cardiac muscle is often much degenerated, and the conclusion is irresistible that it must be more or less degenerated in many of the cases that recover. Sudden death from cardiac syncope often occurs after diphtheria; the author cites seven such cases occurring in his own practice. The clinical indications of such degeneration which should be sought for are these: (1) Feebleness of the pulse wave; (2) feebleness and diffusion of the cardiac impulse; (3) extension of the cardiac dulness to the left; (4) feebleness of the first sound at the apex, with accentuation of the pulmonary second sound; (5) marked accentuation of the aortic second sound without increased tension of the pulse.

Alterations in the normal sounds of the heart may be vastly more important than a murmur. Percussion of the heart is often of the greatest value in determining the presence of dilatation. In diphtheria, if the dulness extends two finger-breadths to the left of the nipple line, there is urgent peril and the child must not be allowed to sit up in bed for any reason whatsoever. The increase in dulness is sometimes very rapid. An extension of one finger's breadth may occur within a few hours. This acute dilatation is usually accompanied by vomiting; this symptom is an important danger signal. When the shock of the acute dilatation has passed off, the patients may look and feel well; yet their lives are in urgent danger. The dilatation may occur at an early period of the disease or even after several weeks. So that a careful watch should be kept on the condition of a child's heart for at least two months after a severe attack of diphtheria. The virulence of diphtheria is more intense in children than in adults. In influenza the reverse obtains; rapid dilatation of the heart frequently occurs within a day or two after the onset of the disease, and it sometimes causes

fatal syncope. It is certain that the dilatation caused by influenza may remain as a permanent dilatation, and may give rise to very serious symptoms. Thrombosis is also of frequent occurrence after influenza, probably due, in part at least, to the enfeeblement of the heart. Minor degrees of dilatation may cause merely a feeling of incapacity for exertion. Active exertion may do such a patient much harm, and any prolonged strain may be followed by an acute breakdown. In rheumatic fever, even in the most subacute attacks, acute cardiac dilatation seems to be invariably present. In later attacks also an acute dilatation is usually present, for it may be observed that the dulness of the left ventricle diminishes as the attack subsides. Yet such dilatation is far less dangerous in rheumatism than in diphtheria or influenza. This difference must be produced by a different effect of the several toxins upon the cardiac muscle. In rheumatism, as in diphtheria, a sudden vomiting is often the danger signal. The slightest suspicion of rheumatism in a child should lead to careful and repeated examination of the heart. Fresh rheumatism often kills by breaking down compensation. Since cardiac dilatation in influenza and diphtheria is due to the toxins of the specific microbes of those respective diseases, the occurrence so regularly of cardiac dilatation in rheumatism points strongly to its being also of microbic origin.

Epidemic Arsenical Poisoning among Beer Drinkers. By Dr. N. Raw, Dr. F. H. Barendt and Dr. W. B. Warrington.—The severe epidemic of arsenical poisoning in Liverpool is subsiding. The contamination of the beer commenced about June, and remained fairly constant until November, when a further increased contamination took place, causing more acute symptoms. The skin affections fall into two classes, those resulting from a sudden debauch, and those due to the daily and not immoderate use of the poisoned beer. The interpretation of the pigmentation is important, and there is no doubt that many cases have been diagnosed wrongly as morbus Addisonii, attributed to phtheiriasis, absence of cleanliness, stress or strain of existence. The most characteristic skin disturbance is the pigmentation. The sensory disorders are brought obtrusively into notice. These are: (1) Numbness and tingling, coming on rapidly in both hands and feet; (2) pain on pressing the soles of the feet; (3) erythromelalgia; (4) absence of objective impairment of sensation; (5) in the early cases the knee jerk is often present and perhaps unusually brisk; (6) ataxia has not been noted.

Clinical and Pathological Notes on a Case of Human Actinomycosis. By H. E. L. Heedale, M. B.—The author reports a case of fatal actinomycosis occurring in a man aged twenty-three years. He complained of a large, inflammatory swelling around the neck. This abscess was opened, and the pus and scrapings of the abscess cavity wall examined for actinomyces granules, but none were found. Several weeks later, another abscess formed in front and the patient developed symptoms of pulmonary tuberculosis. Abscesses continued to form at intervals, and the patient finally died of advanced amyloid disease. Postmortem histological examination of the skin in the neighborhood of the abscesses showed the presence of threads and masses of actinomyces in the subcutaneous layer. The lungs showed a double infection with tuberculosis and actinomycosis. The author looks on actinomycosis as a streptothrix infection.

Note on the Dialysis of the Toxines through Colloidion Walls. By Dr. M. A. Ruffer and Dr. M. Crendipoulo.—The authors have studied the dialyses of the

toxines of the *Bacillus pyocyaneus* through collodion walls, and find that they dialyse, but not in their entirety. The time they take in dialysing is comparatively long, and their pathogenic properties vary according to the length of the dialysis. It is extremely probable that the immunizing substances are among the first to dialyse. Advantage might possibly be taken of this property in the manufacturing of vaccines.

A Case of Renal Colic Attended by the Passage of Casts of the Ureter (Ureteritis Membranacea). By Dr. J. A. H. White.—The author reports the case of a woman, aged sixty years, suffering from repeated attacks of renal colic where the urine passed during the paroxysms contained membranous casts of the ureters, semi-transparent, hollow, cylindrical bodies of clear mucus, held together by a few threads of fibrin. From their flimsiness it is unlikely that they could cause any obstruction to speak of. The author thinks they are due to the irritation produced by an encysted renal calculus.

A Case in which Movable Kidney Produced the Usual Symptoms of Hepatic Colic. By Dr. M. Lawrie.—The author reports the case of a woman, aged thirty-nine years, who for ten years had suffered from pain in the region of the gall-bladder and liver. The pain corresponded in every way to that accompanying biliary colic, and the attacks were always associated with fever. As the right kidney was freely movable, a nephrorrhaphy was performed, the kidney being stitched to the deep muscles of the back.

The operation was successful and was immediately followed by the disappearance of all the troublesome symptoms.

The Sex of Patients Suffering from Gastric Ulcer. By R. de S. Stawell, M. B.—In 7,700 postmortem examinations, of which full notes were preserved, the author found the presence of gastric ulcer recorded in 96; 55 men and 41 women. While during the corresponding period 30,500 men and 30,000 women were admitted to the hospital, yet many more male than female bodies were examined postmortem. During life the cases diagnosed as gastric ulcer in men as compared with women during the same period, were as one to four. The great majority of perforations in women occurring between the ages of eighteen and twenty-eight years, while in men there is a much more even distribution over the decades of life, makes the diagnosis easier in the case of the former.

Presse médicale, December 15, 1900.

Affections of the Vascular Apparatus.—M. Hutinel concludes his interesting historical essay on the development of the pathology and diagnosis of the diseases of the blood-vessels.

Localization of Leprosy Bacilli in Various Organs.—M. Jeanselinc, in concluding his elaborate paper, says that the bacteriological diagnosis of every case of leprosy should always be made in the interest of the community as well as of the patient. The nasal mucus may contain the bacilli in the early stages of the tubercular or maculo-aesthetic forms of the disease. The saliva, the tears or other secretions may show them. The semen, the vaginal secretion, the feces even, may be virulent evokers of the disease, but the urine is free from lepra bacilli. Prophylaxis then consists in rigid disinfection of the nose and skin of leprosy persons, and the perfect occlusion of all ulcerations. All objects of common usage, such as the clothing, should also be rigorously cleansed.

December 19, 1900.

Acute Appendicitis.—M. Paul Reynier, in a polemic article, attacks the operative desire and statistics of M. Routier, and advocates without question an armed expectancy and treatment by ice. The recovery is very slow and prolonged over several months, the author admits, but he thinks it more certain in every case. [American surgeons will be interested in reading the details of this paper.]

Dermoid Polyps of the Pharynx. By M. V. Texier.

Progrès médical, December 15, 1900.

Larvated Epilepsy.—M. Ardin-Delteil goes into the history of larvated epilepsy. He defines it as a form of epilepsy differing from the ordinary disease by the manifestation of strange, curious, and various, nosological features. There may be psychological equivalents in the form of incoordinated movements, of coordinated movements or manifesting themselves as paralyses, vaso-motor and sensory equivalents may predominate in the skin, the viscera, or the circulatory apparatus. There may be vesical or rectal incontinence, seminal ejaculation, migraine or "epileptiform neuralgia," as equivalents for the true epileptic seizure. [The article goes into minute detail in the description of each variety].

Lyon médical, December 16, 1900.

Contagion from Vegetations on Cow's Nipples.—M. P. Aubert relates a case in which a woman who milked a cow with verrucosities on her nipples, developed vegetations simulating venereal warts in the anoperineal regions. Her husband became infected similarly from his wife, and the son had the same eruption upon his hands from milking the same cow. The author raises the question of the possibility of infection of the milk from this source.

Intestinal Ulceration in Arteriosclerosis (concluded).—M. F. Monisset says that intestinal ulceration in persons suffering from arteriosclerosis is usually located in the large intestine. He thinks these lesions are more frequent than is ordinarily supposed, and are due to the changes in the intestinal blood-vessels sufficient to evoke ulceration, plus an increased blood-pressure.

Centralblatt für Bakteriologie, Parasitenkunde und Infektionskrankheiten, December 15, 1900.

Ubiquity of Water Vibrios Similar to those of Cholera.—Dr. J. H. F. Kohlbrugge describes a number of vibrios found in water, with cultural peculiarities similar to cholera vibrios. They gave evidence of being different varieties of the same organism. The differences between the cholera and other vibrios can be definitely settled only by means of Pfeiffer's serum reaction during an epidemic.

Bacteriology of Ozæna. By Dr. Walther Stein. (Continued article).

Bacillus Anthracis in the Peritonæum of the Guinea-pig.—Dr. J. W. van Leent concludes from his experiments that anthrax bacilli perish in the peritoneal cavity of guinea-pigs, even when introduced in enormous quantities and when the animal dies of the subcutaneous injection of the same germ. While the absorption of the bacilli is very dangerous to the animal, the absorption of the fluid from the peritonæum will be beneficial. Foreign bodies, or too much fluid in the cavity, may interfere with the bactericidal action of the peritonæum.

Phagocytosis of the endothelial cells, especially of the omentum, plays an important bactericidal rôle.

Distoma Philodryadum West. By Dr. M. Lühe.

Bacteria as Favorable Cultural Agents. By Dr. Arnold Cantani, Jr.

A New Test-tube Stand for Cultures. By Professor Petri.

Berliner klinische Wochenschrift, December 17, 1900.

Amyloid Degeneration of the Kidneys (*continued article*). By Dr. M. Litten.

Fermentation and Digestive Tests of the Fæces. By Professor A. Schmidt.

Oxidation of Urinary Elements. By Dr. Alfred Jolles.

Pressure Irrigation in Acute and Chronic Gonorrhœa.—Dr. Robert Kutner describes an apparatus of his device for irrigating the urethra under pressure in cases of acute and chronic gonorrhœa. He says his results have been much more satisfactory since he has used this apparatus. The method is based upon the principle of dilating the urethra with a fluid medium to secure the destruction of the gonorrhœal bacilli.

Wiener klinische Wochenschrift, December 13, 1900.

Influence of the Röntgen Rays upon the Skin.—Dr. Robert Kienböck has written an elaborate essay upon this topic. He concludes that certain chemical changes result in the skin from the use of the rays. A "Röntgen-dermatitis" may ensue which may take on an acute or chronic course and varying degrees of severity. Alopecia, desquamation of the horny layer and the nails, hyperæmia and swelling of the skin, may be the only phenomena; or vesicular formation followed by exfoliation and serous or purulent exudation may appear. A dry "burn" may result from the use of the rays. Restoration of the affected skin begins at the periphery. Different parts of the body seem to be differently susceptible, and the total time of exposure plays an important rôle. Individuals differ in susceptibility, children and young people reacting more intensely than older persons.

Schleich's Local Anæsthesia.—Dr. Friedrich von Friedländer has had satisfactory results from the use of Schleich's mixtures for local anæsthesia, but he still thinks too large a quantity of cocaine is employed to render the mixtures absolutely safe for all persons. He believes that the field for local anæsthesia is being gradually extended and hopes for the day when, despite its unpleasant features, it will supersede general narcosis.

Aseptic Bougie for the Induction of Labor. By Dr. L. Knapp.

Wiener klinische Rundschau, December 23, 1900.

Questions of Light Therapy (*conclusion*). By Dr. H. Strebel.

Ætiology of Early Ulcerative Syphilides (*continued article*). By Dr. Jaroslav Bukovsky.

Therapeutic Significance of the Hot-air Douche.—Dr. Julian Marcuse prefers this to the hot-air bath, as it does not necessitate the patient's lying still for hours at a time, and permits the action of the hot air on any desired part of the body. The hot-air douche stimulates the skin and the subcutaneous lymph and blood vessels, and,

combined with massage, forms a valuable therapeutic measure for gouty, rheumatic and neuralgic affections.

New Magnesium Suture. By Dr. Chlumsky.

Riforma medica, December 4, 5, 6, and 7, 1900.

Echinococcus Cysts of the Kidneys. A Clinical Lecture. By Professor G. Rummo.

The Infantile State and Mitral Stenosis (Infantilismo Mitralico). By Dr. Luigi Ferrannini.—The author calls attention to the fact that in many young persons with mitral stenosis there is a marked deficiency in physical and mental development, and an anachronism between the age and the general condition of body and mind. Thus, young women of twenty or over will look and act like girls of twelve, and young men of the same age will appear like boys at puberty. The signs of puberty are generally delayed in these subjects, and in women with mitral stenosis the menstrual function appears late, while the sexual instinct does not appear in men with this lesion until the age of twenty or twenty-two years. The author has had occasion to observe the anthropologic characteristics of a number of patients with heart disease and has come to the conclusion that there is a dystrophic condition in many cases of mitral stenosis, which causes the patients to remain in the infantile stage of development for many years past the period of puberty. He reports a number of interesting cases to illustrate his contention. In summing up, he says that these patients simply present a discord between their age and their physical and mental make-up. After reviewing the literature of infantilism, he states that, in his opinion, there is in these cases a distinct connection between the infantile state and mitral stenosis. Embryologic researches, especially those published by the Hertwigs, have proved that the vascular and osseous systems are derived from the same embryonal tissue, the mesenchyme. The author has shown in previous studies that congenital mitral stenosis depends upon malformation of the leaflets of the valve. The skeleton and the endocardium are developed from the same embryonal layer and it is possible that a connection exists between mitral and skeletal deficiency of development. The author gives the same argument in support of the connection between psychic deficiency and mitral stenosis. The central nervous system and the endocardium are developed from the same layer in some animals. We must also remember that the genital and nervous systems are developed from the same germinating ovum as the mitral valve, and that there is a possibility of a connection between the deficiency or abnormality of one and the others. He closes by saying that in these cases Nature seems to have fashioned a being proportionate to the work which the heart is able to perform.

December 10, 1900.

Concerning Experimental Tuberculosis of the Suprarenal Capsule. By Dr. Bindo de Vecchi.—The author studies the development of the lesions of Addison's disease experimentally by producing artificial tuberculosis in a series of animals. (*To be continued.*)

December 11, 12, and 13, 1900.

Clinical Researches Concerning Laughter, Weeping and Yawning in Hemiplegics. By Dr. Giovanni Boeri.—The author's conclusions are as follows: 1. The cerebral hemispheres do not take part equally in those acts which are performed simultaneously by both sides of the body. This is seen especially in ordinary respiration, as

well as in accelerated or forced breathing and in such reflexes as coughing, weeping, laughing, and yawning. As a result of cerebral lesions, there is usually a more or less pronounced difference between the motility of the hemiplegic side in the affected half of the body during the aforesaid acts. 2. This difference between the two sides depends both on the defect on the paralyzed side, and upon an excess of motility (as regards the reflexes mentioned), which may happen to be on the affected side. Thus it is possible that the movements of respiration, etc., are more marked on the paralyzed side. Hence in coma the fact that one side of the chest is expanded less than the other, does not show which hemisphere is affected.

Gazzetta degli Ospedali e delle Cliniche, November 25, 1900.

Concerning Pseudo-tuberculosis Bacilli in the Sputum of Pulmonary Gangrene. By Dr. Ezio Benvenuti.—The author calls attention to the occurrence of a bacillus in the expectoration of pulmonary gangrene which resembles, both in structure and in staining qualities with the Ziehl-Nielsen method, the germ of tuberculosis. He reports briefly the history of a case in which pseudo-tuberculosis bacilli were found. The autopsy showed no tuberculous lesions, but a focus of pulmonary gangrene. Inoculation of animals with some of the exudate found in the gangrenous focus gave completely negative results, so far as tuberculosis was concerned. A bacillus resembling the germ of tuberculosis in almost all respects, except that it was more resistant to acids and alkalies, was found by Müller in *Phleum pratense*, and in the fæces of cows, goats, and other animals. A similar bacillus was found by Fraenkel and Rabinovitch in a case of pulmonary gangrene. Similar bacilli are also found in butter.

Hæmorrhages in Malaria. By Dr. Lorenzo Bidoli.—The author reports a case of malaria which is noteworthy on account of the irregularity of the paroxysms and on account of the occurrence of hæmorrhages. The case is one of the atypical forms of tropical malaria, of the malignant æstivo-autumnal variety, which tends sometimes to recur at irregular intervals separated by prolonged periods of apyrexia. The hæmorrhages from the stomach and intestines, such as were observed in this case, are not frequent occurrences in malaria, and when they occur they may be regarded as signs of profound systemic infection. The patient whose case is here cited recovered under the vigorous use of quinine and appropriate regimen.

Concerning a Case of Hepatoptosis and Uterine Fibroids. Successful Fixation of the Liver and Hysterectomy. By Dr. Davide Giordano.—The patient was a woman, aged forty-two years, whose father had died of cancer of the rectum. Two years before admission she was seized with epigastric pain, which was so violent that she was confined to bed for two hours. After that she was unable to do her work so well as before, and complained of pains in the epigastrium, and in the region of the transverse and ascending colon. These pains would recur after meals, and continued to reappear at intervals until two months before admission, when vomiting was added to the symptoms. Menorrhagia and metrorrhagia were also present. On examination, a smooth, hard, movable tumor was found in the abdomen, extending from the level of the right iliac spine to a spot two finger-breadths above the umbilicus. This tumor could be pushed under the ribs when the patient was in the recum-

bent position, and came down to its original position when she stood up. The diagnosis was prolapsed liver. The upper line of dulness was at the eighth rib and the liver dulness was continuous with the tumor. On the anterior wall of the uterus a well-marked, hard nodule, of the size of a hen's egg, was felt on bimanual palpation. The incision was twelve centimetres long and followed the edge of the ribs on the right side. The liver and biliary apparatus were found normal in appearance, but the suspensory ligament was markedly stretched. The umbilical portion of this ligament was cut through, as it impeded reposition of the prolapsed liver. A strong strand of catgut was passed through the xiphoid cartilage on the same side and through the suspensory ligament, where it joined the edge of the liver. The ends of the catgut were secured in a clamp and the suspensory ligament was attached by means of this suture to the rib cartilages along the edge of the thorax. The surface between the sutures was cauterized with crystals of phenol on a probe, and the sutures were drawn and tied. In addition, a suture was passed through the liver at a point over the gall-bladder and tied to the last rib. By this means the liver was supported and the prolapse reduced. Abdominal hysterectomy was performed after closing the first wound. The whole operation lasted thirty-five minutes. The patient made a good recovery and regained her health rapidly.

The Single Circular Incision as a Radical Treatment for Varices and Varicose Ulcers in the Lower Extremities. By Dr. Carlo Mariani.

Functional Apathetic Dementia. By Dr. R. Alberici.

Concerning the Therapeutic Value of the Kola Nut. By Dr. Adolfo Pinaro.

Vratch, November 25, 1900.

Report of the Cases of Typhoid Fever Observed in the City Hospital of Nikolaeff. Feeding in Typhoid Fever. By Dr. E. S. Timen.—A series of statistics concerning the cases observed, and a discussion of the question of diet in typhoid fever. At first the diet of all his patients consisted of milk (about one litre daily), beef broth, and of Stoke's mixture in which the brandy was replaced by Marsala. In addition, the patients received a sufficient amount of sour drinks, tea and water. The author found that the majority of patients, who for the most part were laborers, did not drink more than two or three glasses of milk daily. They complained of a sour taste in the mouth and said that they never drank milk in health, and that the diet was repugnant to them. Many begged to be given other food, as they believed that they would starve in a short time if they were to continue on milk. In a number, milk diet was accompanied by accumulation of gases in the intestines, constipation, or diarrhœa which did not disappear on addition of lime water to the milk. Frequent administration of milk in small quantities may be excellent in private practice, but it is impossible in a hospital in which there is an insufficient number of trained attendants. The author, therefore, added to the diet soft-boiled eggs, crackers, and white bread without crust. If the patients did well under this diet, and if the appetite increased, he added chicken broth and half a chicken, or a meat cutlet. It seems that these additions did not depend on the temperature of the patients, as the author describes a scene where patients ate their meat with good appetite after rising from a prostrated attitude with feverish faces. In some cases the patients at first refused solid food, but the nurse was instructed to insist

on their eating what was offered, and the patients rapidly became accustomed to the change of diet. The only rule he followed was that if the patient's appetite was not aroused in a few days after admission, he was kept on milk, but those who had an appetite from the first, or who acquired one after a few days, received solid food as soon as possible. If a patient who had been on solids complained of abdominal tenderness, or showed distention of the intestines, an enema was given, a cold compress applied to the abdomen, and the diet changed to milk. Solids were resumed on the disappearance of the symptoms. The results of this method are given as follows: The total number of patients on solid food was thirty-two. Of these, fourteen got solids after a few days' milk diet, and eighteen about the third week of the disease, when the general condition was good and when the morning remissions were more marked. All these patients recovered. As regards appetite he concludes that in many patients the desire to eat remains, in some it may be provoked by varying the food according to our own notions, or according to the patient's wishes. In no case was there any unfavorable result as regarded the bowels. In most cases the evacuations became more formed, and no pain was complained of. In one case there was a distinct cessation of the diarrhoea on adoption of solid diet. There were small hæmorrhages in two cases. A relapse occurred in one case. The influence of solid food on temperature was not marked. It appeared as though the evening temperature was a little higher on the day of transition from liquids to solids, but the curve returned to its previous status on the following day.

The Treatment of Simple Fractures. By Dr. I. A. Piletzky.—The method of treatment advocated by this author consists in the application of what he terms an "open splint dressing." This dressing consists of a splint fashioned for each case by filling a gauze bag of such size and shape as to enclose two thirds of the circumference of the limb, and of such a length as to encompass the joints to be immobilized, with flax saturated with plaster of Paris mass. The bag with the contents is applied to the limb, leaving the site of the fracture open, and the mass is allowed to stiffen. A few strokes of the hand with plaster of Paris mass will serve to smooth the outside of the bag and to harden its surface. The advantage of the open method is that the fractured place can be massaged without removing the splint. Massage is begun from the first day. At first the limb is stroked from the periphery to the centre. Then it is rubbed, without avoiding the fractured place. If the skin is injured, the lesions are healed first, of course. After from eight to twelve days, according to the case, the splint is removed and passive motions of the joints adjoining the fracture, together with massage of the whole limb, are employed. After the second week, active motion is begun. As soon as the callus is well marked, the patient is allowed to sit up in bed, the extension, if there has been any, is removed, together with the splint, and later the patient is told to stand and attempt to walk with crutches and finally with a stick. Massage is performed twice daily for ten or fifteen minutes at a time. Early massage removes pain, absorbs hæmorrhages, and relieves contractions of muscles. The author reports eleven cases illustrating the success of this method.

Edinburgh Medical Journal, December, 1900.

The Indications for the Operations of Hysterectomy and Myohysterectomy in Myoma. By Dr. H. McN. Jones.—[This article is the sixth of a series entitled

Points of Practical Interest in Surgical Gynæcology.] The author briefly surveys the present attitude of gynæcological surgeons with regard to the operations of supra-vaginal myohysterectomy and hysterectomy. After touching on the biological, morphological, and histological grounds connected with the tumor itself and its immediate surroundings, which may impel the performance of hysterectomy, he takes up the associated clinical complications. Hæmorrhage can no longer be regarded as the one great indication for interference with a myomatous tumor; in a large proportion of cases the bleeding is slight or entirely absent. Marked mental derangement associated with the presence of an abdominal tumor, is an indication for operation. In many such cases the dementia is entirely relieved by the removal of the tumor. Various degrees of peritonitis, associated with acute exacerbation in size of the tumor, may call for interference. In myoma complicating pregnancy, when the tumor is so situated that its removal offers the best chance of saving both mother and child, while noninterference endangers the lives of both, operation should be attempted. Otherwise, labor must be awaited and Cæsarean section, followed by hysterectomy, be performed. The adhesions, pelvic and extrapelvic, which form between the tumor and the omentum, intestine, bladder and rectum, also form serious complications. Too great importance has been attached to the results of the menopause on a myoma. There is no security that after the menopause a myoma will cease to grow or escape suppurative or necrotic degeneration. A table is given in which are classified the principal dangers to life which may arise from the presence of a myoma. As serious contraindications to an operation must be included grave degenerative changes in the kidney or the other abdominal viscera, or profound anæmia associated with organic cardiac conditions. A tumor in which there is no evidence of any serious degenerative change, which is not complicated by gross changes in the adnexa, which is causing no serious obstruction to the bowel or displacement of the bladder with incontinence or distress, where neither peritoneal nor ascitic complications are present, and the rapidity or the size of the growth has not to be considered, will certainly not demand interference.

The General Care of the Skin, Considered from the Point of View of Prophylaxis. By Dr. W. A. Jamieson.—The author discusses the management of the skin and its appendages during health. One essential element in the due care of the skin is not to remove prematurely, or to too great an extent, much of the outer epidermis. The author does not approve of the indiscriminate use of soap; moderate friction is far better, and the loofah forms the best flesh brush. He is a warm advocate of cold baths, where not contraindicated by age or weakness. Hot baths should not be indulged in frequently. Distilled or rain water is by far the best for toilet purposes; hard water acts deleteriously to the skin, yet artificial additions to water for the purpose of softening it, are apt to be harmful. The article closes with some general remarks on the toilet of the hair and nails.

Dental Caries as a Factor of Disease. By Dr. J. R. Leesown.—Hundreds and thousands of people are going about with rotten teeth, carrying with them so many small cesspools in their mouths, filled with fætid abominations of stinking food *débris*, with its teeming population of micro-organisms, and the resulting toxins as concomitants, and daily swallowing these putrefactions, and absorbing the pus. Many cases of septic disease are due to dental caries, and to that alone. Its effects may

be manifested in multifarious ways. The author reports a case of persistent spasm of the right hand, of two years' duration, the diagnosis having been tetany or hysteria. Finally, two septic molar teeth were observed and removed, with the result that the spasm disappeared, not to return. Many of the so-called "scrofulous" scars of the neck have had their starting-point in carious teeth. The usual complaint by patients that fresh air will give them face-ache, is in most cases due to uncared-for carious teeth. Many laryngeal and pharyngeal troubles have their origin in the same cause. A man with a decayed molar hardly ever has a clean tongue. Insufficient mastication of food is another effect of dental caries. Teeth should be cleaned twice a day and always the last thing at night. A toothbrush should be considered as a conglomeration of toothpicks, and used accordingly. Children should never be allowed sweets or biscuits on going to bed. And the teeth should be inspected by a dentist from time to time as a matter of routine.

Observations Relating to the Symptoms and Effects of Oxygen Inhalation. By G. L. du Toit.—The author reviews the action of oxygen on the various systems of the body, on the temperature, on micro-organisms, and on unhealthy tissues. In cases of head-injury or favus, the gas is applied by a tightly fitting cap, connected with the oxygen bag. In abrasions of the face or lupus, the gas is to be applied by specially constructed masks, with a window of glass through which the patient can see. In wounds or ulcers of the thorax, the same kind of mask is to be used. In ozæna, the patient receives the gas through one nostril, the other being plugged with cotton-wool, and he breathes through the mouth, to avoid inhaling the gas. The masks used should not be airtight; ventilation is necessary. The earlier oxygen gas is administered in pneumonia, the better the prognosis for the ultimate cure of the patient. The author has used oxygen with special success in the treatment of wounds and ulcers, acute and chronic. It acts beneficially in alleviating pain and throbbing, it dissipates the heavy, sickly odor of the ulcer, and acts as a powerful stimulating agent without causing irritation of the tissues. The author cites a case of chronic syphilitic ulcer in which oxygen was used with the greatest benefit.

Notes on the Surgery of Joints. By A. Neve, F. R. C. S. Edin.—The author's article is based on a study of 540 joint operations performed at the Kashmir Mission Hospital during the past ten years. The relative infrequency of amputation is noticeable, there being only twenty-eight amputations performed, as compared with 201 conservative operations. The indications for amputation are: (1) great weakness due to suppuration or constitutional disease, where the risk from excision would be too great; (2) where the disease is too extensive for excision; (3) where more than one large joint of a limb is seriously diseased; (4) where the limb, if saved, would be, not only useless, but a hindrance; (5) in patients over fifty years of age, with septic arthritis.

Excision is indicated: (1) in ankylosis with bad position; (2) in traumatic purulent arthritis, where the bones are injured; (3) in tuberculosis of the articular surfaces in adults; (4) in septic sinuses, septic arthritis, and bone disease, where the patient is not too weakened.

Arthroectomy is appropriate for: (1) the same class of cases in an earlier stage; (2) growing children; (3) purulent synovitis resisting milder measures, and (4) chronic tuberculous disease resisting milder measures.

Whatever operation is performed, the surgeon should extirpate every atom of local disease.

The total mortality of the author's cases was 1.5 per cent.; that of the major cases only, 4 per cent.

Archives of Pædiatrics, December, 1900.

Fœtal and Infantile Typhoid. By Dr. John Lovett Morse.—The typhoid bacillus can traverse the abnormal, and possibly the normal, placenta from mother to fœtus. Other organisms may pass in the same way. Infection of the fœtus results. Because of the direct entrance of the bacilli into the circulation, intrauterine typhoid is from the first a general septicaemia. For this reason, and possibly also because the intestines are not performing their functions, the classical lesions are wanting in intrauterine typhoid. The fœtus usually dies *in utero* or at birth as the result of the typhoid infection. If born alive, death occurs in a few days without definite symptoms. It is possible that the fœtus may pass through the infection *in utero* and be born alive and well. There is, however, no proof that this happens. Infection does not always occur. The pregnant woman does not necessarily transmit the disease to her child.

As to the serum reaction: It occurs in infantile, as in adult, typhoid. There are no data as to whether or not it occurs in fetal typhoid. The agglutinating power may or may not be present in the blood of infants born of women with typhoid. If present, it is transmitted from the mother to the child through the placenta. It is possible, however, that it may be formed in the child through toxins transmitted through the placenta. The agglutinating principle can pass through the normal placenta. Part of it, however, is arrested in the passage. Whether or not it is transmitted, seems to depend on the strength of the agglutinating power in the maternal blood, and the length of time during which the placenta is exposed to it. It may be transmitted to the nursing through the milk. It may appear in the infant's blood in less than twenty-four hours. It lasts but a few days after the cessation of nursing. It is always weaker in the milk than in the maternal blood and always weaker in the infant's blood than in the milk. This weakening of the agglutinating power is due to the obstruction to its passage in the mammary gland and in the nursing's digestive tract. The chief factor governing transmission is the intensity of the power in the maternal blood. A subordinate but important factor is some unknown condition in the digestive tract. If the power in the maternal blood is weak and the obstacles great, it may not be transmitted.

Pulmonary Tuberculosis in Infants and Children. By Dr. Frank Parsons Norbury.—Referring to the children of tuberculous parents, the author insists upon the importance of their receiving proper care from the date of birth. Artificial feeding should be used; the infant should not sleep in the room with its mother; kissing should be prohibited, and the child should live in the open air as much as possible. As to drugs: creosote and creosotal in milk, are of value. The simple phosphoric acid in a vehicle of elixir of pepsin, improves the appetite and assists digestion. Paregoric, heroine, one twenty-fifth of a grain, or codeine, one tenth of a grain, may be used for troublesome and persistent cough, combined with some suitable cough mixture. Fever is combated by baths or some of the coal-tar preparations administered with caution.

A Report of One Hundred and Eighty-seven Cases of Measles with Reference to Koplik's Spots and their Value in Diagnosis. By Dr. John J. Cotter.—The results of the author's observations may be briefly indicated by this table:

Koplik's spots, positive.....	169 cases.
Koplik's spots, negative.....	8 cases.
Koplik's spots, doubtful.....	10 cases.

Total.....187 cases.

Poorly nourished children of the type known as marantic, those affected with rickets, or with the taint of hereditary or acquired syphilis, do not present the spots so clearly as their more vigorous companions, and sometimes the spots are absent, while catarrhal symptoms, fever, skin eruptions, etc., may be presented classically and give accurate data for absolute diagnosis. We have yet to know that any disease other than measles presents these spots, and their value in diagnosis should meet with the universal appreciation which their importance demands.

Poisoning by Vapo-cresolene. By Dr. S. S. Adams. —In two cases in the author's experience, most alarming symptoms were found to be due to the presence of a vapo-cresolene lamp. There seems to be no doubt as to the accuracy of the diagnosis, and the author reports these cases because vapo-cresolene is to be found in a great many houses in which there is a child with a cough.

Fatal Intestinal Hæmorrhage without Known Cause in an Infant of Five Months. By Dr. Maurice Ostheimer.

Letters to the Editor.

THE ANTITOXINE TREATMENT OF DIPHTHERIA.

NEWARK, DELAWARE, January 3, 1901.

To the Editor of the *New York Medical Journal*:

SIR: With the last note of Dr. Herman I considered the controversy closed. My confidence in the sound judgment of the general practitioner left no doubt as to the crushing defeat of the "antis" represented by the doctor. Moreover, time alone will show whether the "bell-wethers of bacteriology" or the antediluvian empirics "lead (the profession) into a mire of mistaken conjecture." The purpose of this correspondence is to acquaint the reader who has been patient enough to follow our controversy with some additional facts brought out by a recent contribution by Dr. Zansajlow (Russia) to the *Bolnitshnaja Gazeta Botkina*, Vol. xi, No. 47. During a period of eight years, 1891-1899, there occurred among the employees (and their families) of the Ekateriuin Railroad 1,114 cases of diphtheria. The patients were mostly treated at their homes, and the diagnosis was generally made from clinical symptoms alone. Only in a few doubtful cases recourse was had to a bacteriological examination. Prior to 1895, the 455 cases were treated by local antiseptics, stimulants, and tonics. After 1895 antitoxine was introduced, the antiseptic gargles and stimulants being in addition resorted to in the majority of cases. The total number of patients from 1895 to 1899 was 659. The mortality prior to 1895 ranged between 25 and 32 per cent. With the introduction of antitoxine the mortality at once began to decline, reaching as low as 2 per cent. in 1899 (156 cases). "This decrease of mortality," the author asserts, "is not due, as some contend, to the inclusion of non-diphtheritic cases." That these remarkable results can only be credited to the use of antitoxine will not be doubted by any reasonable person, except Dr. Herman. Furthermore, the Russian writer states that no serious complications followed the use of antitoxine and the greatest benefits were obtained in cases in which the Klebs-Löffler bacillus predominated. The results

were not so good in mixed infections or in cases in which the streptococcus alone was the offending agent.

A. ROBIN, M. D.

Book Notices.

A Manual of Medicine. Edited by W. H. ALLCHIN, M. D. Lond., F. R. C. P., F. R. S. E., Senior Physician on Clinical Medicine, Westminster Hospital, etc. Volume I. General Diseases. Diseases Excited by Atmospheric Influences. The Infections. Pp. x-442. New York and London: The Macmillan Company, 1900.

The first volume of this new *Manual of Medicine* impresses us favorably; as much for what it omits as for what it includes. It is devoted to "diseases excited by atmospheric influences and the infections." Now, in recent years there has been no dearth of systems and text-books and manuals of medicine, which differ among themselves only microscopically. The volume before us differs from this type only in being delightfully smaller (it is a volume that gives one pleasure to hold and to read), in being far less verbose (it is really an excellent presentation of all that is required), and from many, alas, in being well written. That the future volumes will be of excellence equal to that of the first is to be hoped and expected.

Suggestions to Medical Writers. By GEORGE M. GOULD, M. D. Pp. 4 to 185. Philadelphia: The Philadelphia Medical Publishing Company, 1900.

MOST of the articles in this book are mainly reprinted from editorial notes that originally appeared in the *Philadelphia Medical Journal*. Briefly, the work is a plea for (1) a "reform of spelling" by the disuse of diphthongs, diæreses, umlauts, hyphens, accents, and the silent "e," and of silent syllables; (2) the "cur-tailing" of adjectives with the double adjectival endings "ic" and "ical," as, for instance, "pathologic" and "pathological"; and (3) the disuse, so far as practicable, and the anglicizing when impracticable, of all foreign terms, especially the Greek and Latin. The arguments employed are not new, and in our eyes not at all convincing. It is said, for instance, that modern English spelling has no consistency, that it is both physiologically and commercially expensive, and that such changes as are recommended are directly in line with the natural course of evolution.

As to consistency, it seems to us that the only way to attain it, even approximately, would be to carry out to their logical conclusion the suggestions of those same "fonetik fok," of whom the author says that "if there was the slightest danger of this wild communism being translated into fact, they should every one be gibbeted, body and soul." There is in our opinion exactly the same justification for "thru," "enuf," "askt," etc., as for "catalog," "feces," "chlorid," "iodin," and all the other recommended changes.

As to the question of physiological and commercial expense, the time and effort saved, both in business and in school wear and tear, the author expressly discounts that very consideration when, condemning the modern tendency to convert nouns into adjectives in such compound words as "head injury," "heart disease," etc., he says, "Brevity and conciseness are excellent qualities in medical writing, and within certain limitations are to be commended, but *life is not yet so short that we cannot take time to say 'wound of the foot,' 'cardiac murmur,' 'renal stone,' 'vesical disease,' etc., instead of the barbaric*

bunching together of two nouns." (The italics are ours.) Further, when discussing the spelling of hæmorrhage, and so forth, the author asks those who object to "the mutilation of our beloved language," in the substitution of *e* for *æ*, whether they are prepared to go back and spell all the words beginning *pre*, e. g., prescription, etc., with a diphthong, *præ*, as they must do if they are to be consistent. On the same principle we would ask if Dr. Gould is prepared to banish "headache," "daylight," "rosetree," "railroad," *et hoc genus omne*, from his vocabulary. Finally, as to the everlasting talk of consciously proceeding on evolutionary lines, evolution practically means the survival of the fittest. It is only its ultimate survival which proves that it is the fittest. Evolution does not make systems to be worked out; it accomplishes facts. We can only judge what is best for the world as things are, and then only approximately; what is best now for the time to come we cannot know at all. The positive certainty of yesterday is the fallacy of to-day. How long is it since surgeons used every effort to aid the formation of "healthy pus," and cooped up tuberculous patients in stuffy confinement? Let those who think they know how to help evolution along the way it should go, by all means do so; but let them refrain, until time has proved them right, from trying to compel along the same path others who do not see as they see, remembering that, in spite of all the persistent efforts of centuries to eradicate from the Hebrew race that superfluous and possibly insanitary terminal, the Jew is still born with a full allowance of normal prepuce.

The Use of the Sphygmograph in Clinical Medicine. By GRAHAM STEELL, M. D. Edin., F. R. C. P. Lond., etc. Pp. 57. Manchester: Sherratt & Hughes; Philadelphia: P. Blakiston's Son & Company, 1900. [Price \$1.00.]

THIS little work is a collection of sphygmograms accompanied by descriptive text. The first chapter concerns the normal pulse and is introductory, the second relates to the pulse in aortic disease and its sphygmographic illustration, the third to mitral stenosis, the fourth to mitral incompetence, and the fifth to irregularity and intermission. Dependence on the sphygmograph, or even belief in it, is far from general, but one must see that a book like this cannot fail to be of use.

Surgery: Its Theory and Practice. By WILLIAM JOHNSON WALSHAM, F. R. C. S. Eng.; M. B. and C. M. Aberd., Surgeon and Lecturer on Surgery, St. Bartholomew's Hospital, etc. With 483 Illustrations, including 16 Skiagram Plates. Seventh Edition. Pp. ix-953. Philadelphia: P. Blakiston's Son & Company, 1900.

THE seventh edition of this interesting manual on the theory and practice of surgery adds another useful volume to our library. Inasmuch as it covers such an extensive field, we must necessarily expect the work to suffer somewhat from the brevity of its articles and also from the slight consideration devoted to many important subjects deserving of much greater attention. Not only has the present edition been carefully revised, but a hundred pages of new matter have been added. Special attention has been devoted to general surgical pathology, and the portion of the work that treats of it has been almost entirely rewritten. Most of the obsolete matter that appeared in former editions has been omitted; there still remains much, however, which could in like manner have been disposed of to advantage.

The arrangement of the book follows the order estab-

lished by its former editions, and we find sections on general pathology of surgical diseases, general pathology of injuries, injuries of special tissues, diseases of special tissues, injuries of regions, and diseases of regions, and an appendix on amputation, the latter much too condensed to be of great practical value.

As a handy reference manual for the use of students and practitioners the work will find its greatest field of usefulness, and to them it is heartily commended.

The Mental Affections of Children: Idiocy, Imbecility, and Insanity. By WILLIAM W. IRELAND, M. D. Edin., formerly Medical Superintendent of the Scottish Institution for the Education of Imbecile Children, etc. Second Edition. Pp. ix-450. Philadelphia: P. Blakiston's Son & Company, 1900.

THIS second edition of Dr. Ireland's work, under its present title, in reality the third edition, is but little altered from that of two years ago. The praise we gave it then in these columns we gladly repeat. The work brings together studies of able observers on the subjects treated, and, while it is chiefly intended for medical men, it will also be found useful to those who have the care and guardianship of idiots and imbeciles, or who take a philanthropic interest in provisions for their welfare.

Encyclopædia Medica. Under the General Editorship of CHALMERS WATSON, M. B., M. R. C. P. E. Volume I, Brachial Plexus to Digestion, pp. vi-562; Volume II, Diphtheria to Food, pp. vi-545; Volume III, Foot to Hernia, pp. vi-534. New York: Longmans, Green, & Company, 1900.

ONE cannot but be impressed by the wide scope of this system, for it includes practically all that is medical, surgical, or medically specialized and of to-day. We have been inclined to criticize its pretension to be encyclopædic, and have regarded it rather as a "system," but there can be no two opinions as to its inclusiveness and excellence. It is, indeed, a medical library in itself, but a compilation of authoritative treatises such as hitherto would have been collected only after much trouble and expense if at all. To criticize a work like this in detail is an absurdity; one might with almost equal appropriateness endeavor to critically review the *Encyclopædia Britannica*, but we can express our appreciation of the work and our admiration of its quality as well as of its quantity. If one wishes a work which contains about all that medically is of importance, arranged not by classes and subjects, but alphabetically, it is to be had in the *Encyclopædia Medica*.

A Practical Treatise on Fractures and Dislocations. By LEWIS A. STIMSON, B. A., M. D., LL. D. (Yalen.), Professor of Surgery in Cornell University Medical College, New York, etc. Third Edition, Revised and Enlarged. With Three Hundred and Thirty-six Illustrations and Thirty-two Plates in Monotint. Pp. xxii-19 to 842. New York and Philadelphia: Lea Brothers & Company, 1900.

THE rare and invaluable experience of the author in this special field of surgery, combined with an astute power of observation and deduction, has enabled him to present to the profession a work which has established itself as a safe and valuable guide to the diagnosis and treatment of both fractures and dislocations. That the work has been appreciated is evinced by the fact that a little over a year has elapsed since the appearance of the last edition. In the present one we recognize the same features which characterized its predecessor, with the ad-

dition of a number of valuable and important statements which the rapid strides in surgery have made mandatory. Of the more important, we may mention the better recognition of the ætiology and manifestations of traumatic hæmatomyelia, the importance of which has only lately been called to the attention of the surgeon. It is to be regretted that the author has not devoted more space to its diagnosis from pressure on the cord; for fuller information the writer refers us to the papers of Bailey and Bolton. We miss also the mention of the cocainization of the spinal cord in the open operation for the relief of pressure symptoms, although it would seem to us to be worthy of mention. As of almost equal interest might be mentioned the author's simple method of reducing certain dislocations by simple continued traction.

Some twenty new illustrations have been added or substituted for obsolete ones, and the number of plates and skiagrams has been materially increased. It has been our pleasure to speak most highly of former editions and we can only add that the present one is even more attractive and instructive than its predecessors.

Modern Surgery, General and Operative. By JOHN CHALMERS DACOSTA, M. D., Professor of the Principles of Surgery and of Clinical Surgery, Jefferson Medical College, Philadelphia, etc., etc., with Four Hundred and Ninety-three Illustrations. Third Edition, Revised and Enlarged. Philadelphia and London: W. B. Saunders & Company, 1900.

WE are happy to note the advent of the third edition of Dr. DaCosta's *Modern Surgery*. The welcome accorded the former editions has prompted the author to increase the present volume by two hundred pages to admit of sufficient space to include a quantity of new matter, made necessary by the rapid progress in surgical development. The original plan and scope of the work have not been materially changed in the present edition; as in the former, the greater part of the first half is devoted to general surgery. Each subject is approached in an able and careful manner, with a strict avoidance of all redundancy of language and padding, leaving the student a clear and succinct idea of surgical diseases and injuries and concluding with the best means of meeting the difficulties. In the second half we find the greatest number of changes in the book by the addition of the newer surgical operative procedures, which brings the book quite up to date. We find also the addition of two new articles, one on the examination of the rectum, the other on the use of hot air in the treatment of diseased joints.

The work is characterized by a thorough condensation of all necessary surgical information, expressed in a terse and clear style, which will continue to make the work most attractive to the student and practitioner.

Miscellany.

Ancient Mexican Medicine.—The *New York Times* for January 6th publishes some foreign correspondence from the City of Mexico in which it is stated that the primitive Mexicans recognized and classified the principal diseases and their principal remedies, and each one had its system of treatment. They understood the virtues of cold water and of vapor baths, both being favorite remedies for a number of diseases.

They also practised blood-letting, and used as lances

the sharp-pointed ends of the maguey plant, from which pulque is made. The setting of fractured limbs was done with skill, and surgeons even ventured with success upon trepanning, and when their surgeons made painful operations they gave narcotic and stupefying herbs to deaden the pain.

In all the markets at the present day Indian men and women are seated on the ground surrounded by strings and wreaths of herbs, while little piles are neatly arranged for sale. The elder ones do not hesitate to say, when asked to diagnosticate an ache, "That pain you complain of in the back of your neck and head is from your nervios ninos; you should take le cedron; here I have fine, fresh leaves for you." For every ill under the sun they have something to give relief.

It is often these same innocent-looking, manta-clad folk who baffle the government by bringing in the Marihuana, which sends its victims running amuck when they wake from the long, deathlike sleep it produces. Weak friends manage to secretly convey it to friends in the big prison of Belém, or wherever they be, and woe be to the luckless guards first to meet the crazy victim of the harmless-looking plant.

The system, recently inaugurated, of baking patients for various ailments is antedated in the hot lands of Mexico. Curious ovens are dug in hillsides, connected by little tunnels, with small furnaces, also dug in the earth. Fever patients, rheumatics, and kindred sufferers are placed in the ovens with only the head above ground, and subjected to all the heat they are equal to bearing. No thermometer tests the heat, and no scientific instruments register the heart beats. Occasionally the process is too thorough and lasting. The result is not good, but the idea is there.

In the State of Vera Cruz in isolated Indian villages when small-pox is epidemic, holes of proper length are dug in the ground; a bed is made in them of new barnyard droppings, with banana leaves spread over. The sick one is laid upon that and covered with more leaves. It is a terrible ordeal, but if the patient can be prevented from taking cold the result is often good, and the recovery rapid.

Tumors Complicating the Puerperal Period.—At a meeting of the New York Obstetrical Society, held on December 11th, the president, Dr. H. J. Boldt, in the chair, Dr. E. B. Cragin presented specimens from two cases of tumor complicating the puerperium and requiring operation. The first was an ovarian cyst, of which the pedicle had become twisted during the puerperium. The second was a large myoma, which began to show necrotic changes during the puerperium. The history of Case I was as follows: A primipara, nineteen years of age, at full term, was delivered at the Sloane Maternity Hospital, on October 20, 1900, of a male child weighing seven pounds and two ounces, after a short, dry labor. After delivery there was found high up on the right side of the abdomen an ovarian cyst with a long pedicle, which allowed the tumor to be moved to nearly all parts of the abdomen. Her puerperium was normal until the fourteenth day, when the temperature rose to 101.2° F., and for ten days fluctuated slightly above and below this point. For the succeeding six days the temperature gradually fell to 99° F., the pulse during the sixteen days ranging between 90 and 110. On the thirtieth day of the puerperium the patient was seized with an attack of vomiting and was unable to retain food during the whole day. The tumor at the same time became more tense and tender. There was slight change in either pulse or

temperature, but, the vomiting and tenderness of the tumor persisting, a diagnosis of twisted pedicle of the tumor was made, and the abdomen was opened on November 19th. An ovarian cyst of the size of a large cocoon was found springing from the right side; it was purple in color, and its pedicle was twisted one turn and a half. The left ovary was the seat of a dermoid cyst of about the size of an egg. Both tumors were removed, and the abdominal wall was closed in layers. The union was primary and convalescence uneventful.

Case II was that of a woman, forty-four years of age, admitted into the Sloane Maternity Hospital on September 8th. Her last menstruation had occurred early in January. For two years she had noticed a large, hard tumor in the abdomen; her menstruation had always been regular, of the three-weeks type, lasting from three to four days. On examination, a large, hard tumor of the size of a foetal head was found to the right of and a little in front of the fundus of the gravid uterus and intimately connected with it. During the next month the mass rotated so as to be more behind the fundus, but before labor it resumed its former position in front and to the right. At full term, on October 25th, after a prolonged labor, the child, weighing seven pounds and ten ounces, was easily extracted by the low forceps operation. Credé's method of expression failed, and the placenta and membranes were extracted manually, both being very adherent. The woman lost thirty-eight ounces of blood and her general condition was poor, her pulse 112, and her temperature 99.6° F. For twenty-four hours the temperature gradually rose, until it reached 104° F. Three days later it dropped to 101° F., at which point it remained for twenty-seven days. On the thirty-second day of the puerperium, as the patient seemed to have made very little if any improvement, abdominal hysterectomy was performed, and the specimen removed, which was now presented. Although the cavity of the uterus seemed normal, necrotic changes had begun in the substance of the tumor, which seemed to be a myoma. The uterus, with the tumor, weighed eight pounds and two ounces.

Dr. A. Palmer Dudley, in the discussion, asked Dr. Cragin why he had delayed so long after the confinement before operating, also, if he would advise others not so well equipped to watch a labor like that and risk the death of the child in order that he might get a normal labor. Dr. Dudley then reported the case of a patient who had been brought into the Harlem Hospital in an ambulance. The child was dead, and the mother was delivered by the house surgeon. She made an uneventful recovery. On the tenth day after delivery he had performed abdominal section and removed sixteen fibroids from the uterus, four of which were larger than an orange, the others ranging in size from that of a walnut to that of a pea. As he removed one of the larger fibroids, he made an incision into the uterine cavity and found that in the delivery the uterus had been cut by the forceps and that the temperature had been due to the injury to the uterine walls, and not to the fibroids. The recovery was uneventful. Dr. Dudley asked Dr. Cragin if, in a young woman, he would in a similar case to the one he presented, venture to do a myomectomy and drain through the cul-de-sac. In the case reported by Dr. Dudley, the patient had recovered and now had a healthy uterus with normal ovaries.

Dr. Cragin, in answer to the question why he had let the patient go so long in labor with the hope of a normal delivery, would say that he had realized that she was in the hospital, where a Caesarean section could be done

within an hour's time if it was deemed necessary, the patient being under close observation. Then, again, while the tumor at first was in front of the child, it was noticed that the fibroid was gradually getting behind the child, out of the way of the canal, and so it was thought best to trust to Nature. In answer to the question why he had waited so long before removing the uterus in the puerperium, he said that the patient had lost considerable blood (thirty-eight ounces) at the time of delivery, had albuminuria as well, and was in a generally poor condition, and that therefore he had not cared to subject her sooner to a radical operation. He had found some decidua retained in the uterus over that part of the cavity against the tumor, and realized that there was some sapraemia, and from that, and as she seemed to be holding her own, he had waited. But when, at the end of thirty days, she was no further along than at ten, he thought an operation was indicated. In reference to Dr. Dudley's question of myomectomy, he would say that in the present specimen one could see that the whole posterior wall of the uterus was involved in the tumor, and that therefore myomectomy would have been a hazardous undertaking.

Ruptured Tubal Gestation Sac.—At the same meeting Dr. Brettauer demonstrated a specimen of ruptured tubal gestation sac which he had removed from a patient with the following history: Age twenty-nine, married six years; one miscarriage two years before, in the second month. She had always menstruated irregularly, her last period having been three weeks overdue, when she came under his observation, on November 4th. About two weeks before she had noticed an occasional pain in the lower abdomen and morning nausea. On the morning of November 4th, during an attack of vomiting, she had severe pain in the abdomen. She was put to bed, and a physician summoned. He found her in an exsanguinated condition, practically pulseless. Active stimulation improved her condition to such an extent that an operation was practicable five hours later. The abdomen was opened and found to contain an immense amount of fluid and coagulated blood, more than he had seen in cases of rupture after pregnancy had progressed for three or four months. Owing to the collapse of the foetal sac, which was formed by the uterine end of the tube, after the expulsion of the ovum, it had at first been difficult to see which side was the offending one, as both tubes were apparently normal; only on closer inspection, an opening was seen in the right tube, close to its uterine end, almost a quarter of an inch in diameter, with sharp edges. The ovum entire was found free in the abdominal cavity. The patient stood the operation better than was expected, but succumbed on the ninth day to a septic infection starting from a widespread necrosis of the abdominal fascia.

Dr. Brothers said that, in his opinion, syneope was a valuable aid in the diagnosis, but he recalled the case of a patient operated upon five days before, in which there was absence of both pain and syneope. At the operation there was considerable blood in the peritoneal cavity, and yet the patient had not had syneope.

A Metallic Obstetric Phantom.—At the same meeting Dr. Edgar presented a metal pelvis, with metal foetal head attached, the head being connected with the pelvis by means of a "goose-neck" series of universal joints, allowing the head to pass into and through the pelvis in any of its diameters. The goose-neck was long enough to give ample scope to the movements of the head, and the contrivance was of the greatest value in obstetric teach-

ing. By means of it the student could be thoroughly taught the mechanism of labor in all presentations, and also the delivery and extraction of the after-coming head. Dr. Edgar also presented several varieties of obstetric bags in which the various bottles and jars were contained in a canvas case which could be easily cleansed. The gown, forceps, Kelly sling, and other articles were wrapped in separate packages, all distinctly labeled. The cost of one outfit was ten dollars, and that of the more elaborate case, with metal trays (described before by Dr. Edgar in detail), eighteen dollars.

Dr. Dickinson believed the outfit could be made much lighter by carrying the vaseline in tubes instead of glass jars, and he himself did not carry the metal pans except when laparotomy was to be performed.

Dr. Marx thought that the Kelly sling was superfluous, as a twisted sheet could be easily prepared at any time. He thought the large tray in the Edgar outfit of great value in resuscitating asphyxiated infants, and he used the smaller one for the forceps.

A Plea for the Recognition of Some of the Factors in the Mechanism of Labor.—Dr. Malcolm McLean, at the same meeting, read a paper with this title. He declared that the great immunity from evil results of radical operative interference was due to close observation of the laws of germ invasion. The evil resulting from the neglect of these laws obscured the brilliancy of our modern science of obstetrics. He believed that in many cases serious traumatic incidents had resulted from a well-defined ignorance of the principles governing the mechanism of labor. Not only did the patient (and perhaps the child) suffer, but the obstetrician was mentally biased as to the difficulty presented in just such cases. It appeared to the writer that injuries to the genital tract were about as frequent as in years gone by, and that a few new and not trifling ailments had been added to the list of unhappy sequelæ by some of the modern attacks on the mother's tissue. The loose-jointed pelvis and the mutilation following extirpation of the uterus, tubes, ovaries, or all together, were instances of these. In the mechanism of labor it must be remembered that, first of all, there was marked softening and relaxation in all the structures to be involved in the passage of the child from the uterus into the world, to allow of the enormous distention to which the parts were to be subjected. As the changes normally occurred, it was important to avoid an artificial mechanism by too hasty interference when the mother's tissues were unprepared and rigid. As a rule, these changes required more time in the primipara than in the multipara. Again, the changes which took place in the shape of the presenting part must be carefully observed, as a very considerable disproportion between the foetal head and the pelvis would be effaced by the moulding of the head as it was compressed within the walls of the pelvic canal. An arrested head with increasing scalp tumor must not, however, be mistaken for the moving and moulding head. The membranes should be preserved intact until the dilatation was complete. When this had occurred, and the membranes drew flat and stiff across the uterine mouth with every pain, instead of protruding, bag-like, to the point of rupture, we might be able to avoid unnecessary delay and assist with propriety by rupturing the sac. All excitement, mental or physical, which interfered with the rhythmic recurrence of the uterine contractions, put so much difficulty in the way. The impropriety of the use of ergot would be apparent if it was remembered that the only effect ergot could have was to cause tonic contraction to take the place of proper

intermittent uterine contraction and relaxation, and voluntary effort on the part of the patient to bring into play the accessory forces of the abdominal muscles should be limited to the second stage. Earlier efforts would result only in fatigue, and the uterine muscle would be made more irritable. In labor with breech presentation the observance of this law was most valuable, and the writer had demonstrated this in the recording of thirty odd consecutive deliveries by the breech without the death of a child. In quite a number of instances the cord, during the last few months of pregnancy, became wound about the child's neck and also about the arms and shoulders in such a way that forward rotation was prevented, and a persistent occipitoposterior position might result. It was in such cases that manual rotation was so unsatisfactory. The occiput itself might be turned forward, but when the hand was removed one found the brow caught by the forceps. In such a case, if the instrument was removed, and the hand used to rotate the occiput around posteriorly to the opposite sacro-iliac joint, the position would be retained. This was due to the unwinding of the misplaced funis. The writer then emphasized the great importance of using the foetal envelopes as a rubber glove in intrauterine manipulation. In this way, if germs were introduced, they would remain in the amniotic sac and come away with it, the uterine wall having been protected from contamination by the foetal sac. In some cases of rupture of the uterus the foetal sac was pushed through the rent, in front of the escaping foetus. If the child was drawn back in the uterus, it might be extracted with the secundines, no liquor amnii having entered the peritoneal cavity. The writer had reported such a case to the society. In the expulsion of the placenta and membranes the accessory action of the abdominal muscles was valuable. In the opinion of the writer, it was not desirable to use intra-uterine douching after labor, for the reason that the sinuses were plugged with sterile clots, and these should not be disturbed in our endeavor to destroy germs which did not exist there. Chloroform was of value to control too violent advance of the presenting part through an unprepared vulva, but, except in instrumental delivery or some other major operation, it should be given only to the obstetric degree. In breech delivery chloroform should not be given after the breech had crossed the perinaeum, for it was just here that we wished the action of the voluntary muscles. The long-continued use of chloroform tended to relax uterine contraction for hours, hence to induce post-partum hæmorrhage. In the mechanism of labor it must be remembered that the head in its passage through the pelvis described a spiral course, and where the high forceps operation was done, the tendency of the blades was to throw the head around in such a way that its largest diameter engaged in the conjugate, or shortest, diameter of the pelvis.

Traction under these circumstances might result in the gravest of injuries. The writer recalled one case in which four operators had striven in vain to extract a head in that position, with the result that both mother and child perished. An autopsy revealed the fact that the head would sink to the floor of the pelvis by its own weight when turned in a flexed condition into one of the oblique positions.

Dr. Cragin said that the more we studied the relations existing between the presenting part and the brim, and the more attention we gave to pelvic measurements, the better the results would be.

Dr. Dickinson emphasized the importance of making use of the amniotic sac as a glove in the removal of the

placenta. The cord should be used as a guide to the opening in the sac, and the membrane used as a mitten in peeling off the placenta. In the matter of rotation in occipitoposterior cases, he said that the trunk as well as the head should be turned forward.

Dr. Edgar spoke of the frequency of imperfect flexion and of the delay it caused in labor. If flexion could be increased by the pressure of the finger, labor would progress more rapidly. He preferred ether to chloroform in obstetric work. He could not agree to the statement that it was a safe practice to grasp the chest of the child and turn the fœtus round, then leave the case to Nature, for fear of having intra-uterine respiration. He would prefer version and extraction if the head did not engage immediately after the procedure of rotating the trunk, and in some cases the forceps was very valuable.

Dr. Dickinson said he wished to go on record as protesting against version in these difficult cases of occipitoposterior positions as compared with high manual rotation followed by the use of the forceps at once.

Dr. Simon Marx believed that the best procedure in persistent occipitoposterior positions above the brim was podalic version followed by extraction. He had not used an intra-uterine tube after labor in a number of years. He had seen excellent results after the administration of quinine in labor.

Illegal Practice in the County of New York.—The Medical Society of the County of New York is sending to physicians the following circular, dated December 15, 1900:

"The medical laws of the State of New York provide that, before one can practise medicine, a certificate of proficiency shall be obtained from the Regents of the University of the State, which is given only after a satisfactory examination. The purpose of this law is to protect the people from incompetent practitioners of medicine, and, in so far as the medical profession is concerned, this purpose is accomplished.

"There are, however, many irregular practitioners who practise in open defiance of this law, apparently without molestation. This is an incentive to irregular methods, and can only be to the disadvantage of the community at large.

"It is the purpose of the Medical Society of the County of New York to begin an active crusade against these unlicensed, and therefore illegal and incompetent, practitioners, and we ask the cooperation of the profession and the public generally.

"Any information concerning unlicensed practitioners will be gratefully received by the board of censors and the counsel of the society, and will be considered confidential when requested.

"Communications can be addressed to the members of the board of censors or to the counsel.

Jurisdiction over a Medical College in the Philippines.—The first question dealt with by the Taft Commission affecting the Church and the United States Government in the Philippines is whether the control of the San José Medical College is vested in the Government or

in the Church. The college was established by bequest in the seventeenth century, and the Jesuit order was given the control of it. When the authority of the Jesuits in the Philippines ceased the Spanish Government assumed direction of the college, and later permitted the Dominican order to conduct San José College as part of the University of Santo Tomas. Following the American occupation, a representative of the people insisted that the college under the treaty of Paris came into the control of the United States, and ought not to be controlled by the Church. The Church authorities claimed the Church had full legal possession. General Otis closed the institution. If the commission decides that the control is vested in the Government, litigation is considered probable.

Since the foregoing was written, press dispatches from Manila, dated January 5th, state that the decision of the Philippine Commission in regard to the San José Medical College case unanimously refers the settlement of the questions involved to the courts, and provides trustees, who, with the assistance of the attorney-general of the Philippines, will inaugurate and prosecute the litigation. The sum of \$5,000 is appropriated for the expenses of the suit.

Many listened to the reading of Judge Taft's opinion in English and Spanish.

A bill has been passed carrying out the terms of the decision. It appoints five physicians as trustees, including Dr. Tavera, who is the complainant throughout, and Colonel Greenleaf, the chief surgeon in the Philippines. The trustees are required to begin a suit within a month in the supreme court of the Philippines, to determine whether the ownership of the college is in the Church or the Government. The Dominican rector of St. Thomas University and Archbishop Chapelle are required to defend the suit and establish the claim of ownership upon the part of the Church. The act provides that the decision of the Philippine court is not to be so final as to make it impossible for Congress to provide an appeal to the United States supreme court.

The opinion says:

"A case involving the construction of the treaty of Paris and the effect upon public trusts of the transfer of sovereignty from a kingdom in which Church and State are united and inseparable to one in which Church and State are entirely separated is of such import that it ought to be submitted to the highest tribunal."

The commission recommends that General MacArthur rescind General Otis's order suspending the conduct of the medical college under the rector of St. Thomas University.

The Origin of Ovarian Cysts.—Mary Dixon Jones, M. D., F. R. M. S. (*American Journal of Obstetrics and Diseases of Women and Children*, xlii, 4), gives an interesting summary of the views generally held as to the origin of ovarian cysts. She combats them all, and declares that cysts are always of inflammatory origin. She draws the following general conclusions from her own investigations: 1. Cyst formations are the outcome of disease. 2. No ovarian cyst, small or large, exists without a previous oophoritis. 3. Other things being equal, the more intense the inflammation the more rapid is the growth of the cyst. 4. There can be no cyst without a reduction of the tissues to protoplasm. 5. This reduction to protoplasm is what we call inflammation. 6. Cysts are always the result of inflammation and are always accompanied by more or less pain, distress, and disturbance of the general health.

Original Communications.

GASTRO-ENTEROSTOMY
BY THE ELASTIC LIGATURE.

By THEODORE A. MCGRAW, M. D.,

DETROIT, MICH.

IN 1889, '90, and '91 I was exceedingly interested in the study of the various methods of making intestinal anastomosis, and for a long time I worked with the object of making some instrument which would expedite the performance of the operation, secure the patient from all danger of intestinal sepsis, and, at the same time, make an immediate communication between the hollow viscera and permit the passage of food. My ingenuity was, however, not equal to the task which I had undertaken, but I, nevertheless, hit upon a method of making intestinal anastomosis which is unequaled in the rapidity of its execution, its efficiency, and its safety, although it does not accomplish its purpose until after the lapse of two or three days. This method is by the application of an elastic ligature, binding the two viscera together and ultimately cutting its way through. I made many experiments on dogs, and operated twice on the human subject, when I was diverted from the method of my own invention by that ingenious device which has made the name of Murphy famous all over the world. I became charmed with an invention which seemed to meet the very indications on which I had spent so much useless labor. I, besides, exaggerated in my own mind the disadvantages connected with the use of the ligature, in the time which must elapse after its application before the patient could take food by the mouth. I therefore abandoned its use for the time being, and during the last nine years have employed the button instead. There are, however, some disadvantages connected with Murphy's method which, every now and then, cause embarrassment if not disaster. I have three times failed to find the button, and twice it has been discovered postmortem in the stomach long after the operation. I am by no means sure that a metallic button bouncing about in a cancerous stomach has no injurious action on the ulcerated surface. In the experience of other men the button has at times failed to hold the viscera together and the intestinal contents have escaped into the peritoneal cavity, causing death. At other times its lumen has become occluded by particles of food or by fæces. It is, too, by no means always easy to insert and fasten in place, the more especially when the efferent gut has become contracted and small. For these reasons I have recently recurred to my old device, and after more, though limited, experience, have wondered at myself that I should ever have abandoned it.

When I experimented with the elastic ligature in making communications between hollow viscera I supposed that I was the first in this field of surgery. I found afterward that Dr. Gaston, of Atlanta, Ga., had published experiments, in 1884, with the elastic ligature as a means

of uniting the gall-bladder to the duodenum. In 1888 Dr. Franz Bardenheuer had also made experiments on dogs with the same purpose, and published his conclusions in a paper entitled *Experimentelle Beiträge zur Abdominal-Chirurgie* (J. Dietz und Baum'sche Druckerei, 1888).

Neither of these surgeons, so far as I can learn, achieved any practical results from his labors. The method is not suitable for the production of anastomosis between the gall-bladder and intestine, as the thinness of the gall-bladder permits the ligature to cut its way through before the viscera have become sufficiently glued together. Dr. Bardenheuer's method was wrong in technique, and therefore of little value in practice. He sought to accomplish the purpose by uniting the intestines by three or four rubber ligatures which were joined together in loops like a chain, each loop containing about one centimetre and a half of tissue. This method was not only difficult and tedious, but also insufficient, and had the further disadvantage of making numerous holes in the viscera and thus multiplying whatever danger there might be from infection.

My experiments with the elastic ligature were made in 1890 and 1891, and my first operation on the human subject was performed on January 8, 1891. I was, that year, chairman of the Section of Surgery of the American Medical Association, and made the matter the subject of my address before that body at its meeting in May, 1891. The address was published in the *Journal of the American Medical Association* on May 16, 1891. I will quote from that address as much as refers to my method of operating and to my first operation on the human subject.

"In my experiments I tried three kinds of ligatures. One, a large, round rubber cord four millimetres in diameter, was speedily discarded. It was too large, was clumsy to tie; when tied it took up too much room and tore too big a hole through the intestinal wall. A second consisted of a flat rubber band three millimetres in width. This proved to be serviceable and can be advantageously used if the third variety cannot be obtained. The third kind, a rubber cord two millimetres in diameter, is that ordinarily used for the ligature of piles. It could not, for some reason, be obtained for my first experiments, but is to be preferred to all others on account of its smoothness, elasticity, and great tenacity. By shaving the end of the rubber thin it may be drawn through the eye of a so-called worsted needle (a needle with a long eye) smaller than itself. This is a decided advantage, for the reason that it is important to make as small a hole as possible through the intestinal wall, and also to have the ligature not only completely fill, but even to distend the hole so as to prevent any extravasation of fæculent fluid. Now, by stretching the rubber during its passage and rendering it thin and small, it may easily be drawn after the needle, and its subsequent contraction will then largely increase its size and cause it to more than fill the orifice. The ligature in the most cases was passed

through the gut in the direction of its long axis and at points most distant from the mesenteric attachment. Before passing it the bowels were stitched together by from three to six Lembert stitches, and afterward similar stitches above the ligature served not only to give additional protection, but also to bury the rubber in the intestinal folds. Usually an inch or more in length was included in the ligature. After the cord had been drawn through both coils of intestine it was tied as tightly as possible in a square knot. Although this knot will ordinarily hold without further fastening, yet, as I wished to cut the ends very short in order to cause as little peritoneal irritation as possible, I always secured the ends so as to make slipping impossible. At first I did this by running a fine needle threaded with silk through the ends and thus tying them together, but, as this procedure was awkward and consumed much time, I later on adopted a suggestion of my student, Mr. Hickey, and secured the knot by tying a silk thread, which was laid under it, first over the first turn of the knot and afterward over the completed knot. This consumed almost no time and fastened the rubber securely against the possibility of accident. In making the knot, the ligature should be drawn as tightly as possible without breaking.

"The first effect of the ligation was to draw the intestines together into folds, and I was not a little apprehensive at first, lest these folds, agglutinated together, might be fixed in a permanent corrugation. In this I was agreeably disappointed. Examination of the intestines, even after so short a time as twenty-four hours, and before the ligature had made any perceptible progress in cutting through, would find these folds in process of obliteration. In some way the intestine accommodated itself to its new conditions and became speedily smooth and shapely. In some respects the early disappearance of these corrugations has been quite a puzzle, as I should have expected them to remain until the intestine was released from the binding cord. I feared, too, lest the ligation and folding of the intestinal wall might cause irritation or even obstruction of the gut. When we consider, indeed, the severity of the symptoms produced by the pinching of even a small segment of a gut in strangulated hernia, we might reasonably expect the occurrence of similar phenomena, with the extreme pinching of two adjacent intestines held together by a tightly drawn rubber ligature. This, however, never happened. Obstruction occurred in one or two cases from a too acute bending of an intestine, but the ligation itself seemed in no case to produce distress—even in gastro-enterostomy, where the involvement of the stomach in the ligature might warrant fears of an uncontrollable gastric irritability, this did not occur. The man upon whom I operated by forming a gastro-intestinal enterostomy for the relief of a pyloric cancer, vomited only once after the operation, namely, on the third day.

"It is evident that the mere pinching or constriction of a portion of the intestinal wall is not in itself a cause

of great irritation, provided the nutrition of the gut is not seriously interfered with. In fact, the symptoms which followed the operation seemed in no case to depend merely upon the injury done to the intestine. If the wound ran a perfectly aseptic course, the animals would show no distress whatever. If it became septic they would suffer accordingly. Every one who has operated on dogs knows the difficulty of making and keeping them aseptic, especially in confined quarters. From lack of proper facilities, I lost several animals from septic peritonitis. It was noteworthy that the origin of trouble was rarely to be found at the seat of ligature or connecting with the cavity of the intestine, for the ligature, in fatal cases, was almost always found buried in the intestinal fold and progressing its usual course, while the distant peritoneal surfaces were covered with lymph or pus. In no case was there found any escape of fæces or intestinal contents into the peritoneal cavity.

"The normal course of the ligature and inclosed tissues was about as follows:

"Animal killed after twenty-four hours showed no change in the condition of the intestines operated on, except a partial obliteration of the folds caused by a ligature and an adhesion of the adjacent peritoneal surfaces. No opening became as yet apparent at the seat of ligation. After forty-eight hours the intestines resumed their normal shape, all folds had disappeared, the adhesions had become firmer, and the rubber was seen to have slightly cut through the inclosed structures. At the end of seventy-two hours a free space usually appeared on each side of the ligature, through which water could be made to pass from one intestine into the other. The ligature still hung in the middle on uncut tissue. At the end of the fourth day the opening became complete, the ligature disappeared, and the anastomosis was accomplished. As the ligature cut through, the edges of the mucous membranes of each gut became glued together and united, and the result was a smoothed, healed edge all along the opening. The irritation caused by a rubber ligature in the peritonæum was just sufficient to cause adhesion of the surfaces with the intervention of hardly any appreciable amount of exudation. The length of the orifice formed was found to be equal to that of the tissue inclosed in the knot. Whether subsequent contraction with partial obliteration of the orifice, such as has happened after other methods of producing anastomosis, would follow in course of time, is as yet uncertain. Variations were occasionally found in the course described. I have seen the opening completed at the end of the third day, and have seen it incomplete at the end of the fifth, but in general, if the operation is done as I have described it, the result will be as I have stated.

"In my first series of experiments I operated on twenty-four dogs, and then, having become convinced of the perfect feasibility of the operation, I chose it in preference to other methods when called upon to establish an

anastomosis between the stomach and small intestine in a case of pyloric cancer.

"Subsequently, seven dogs were operated on for the purpose of studying the effects of the operation in relieving intestinal fistulæ and false anus, and eight others for the production of fistulæ between the gall-bladder and small intestine. The history of the only case in which this method of operation has been thus far employed on the human subject is as follows:

"Mr. Otto Cook, aged fifty-nine years, a Belgian by birth, a farmer by occupation, by the advice of his physician, Dr. John Monaghan, since deceased, entered St. Mary's Hospital on January 8, 1891, to place himself under my care for cancer of the pylorus. He had been perfectly well until three years ago, when he had begun to suffer from indigestion and occasional attacks of vomiting. The trouble gradually increased until he found himself during the last three months unable to retain any food whatsoever. He became gradually very weak, and at the time he entered the hospital very much emaciated. His breath was foul, and his food was vomited regularly a few hours after its ingestion. Examination revealed a tumor as large as a hen's egg, four centimetres above and four centimetres to the right of the navel. This tumor was immovable, and was evidently adherent to the adjacent structures.

"January 9th.—The stomach was washed out with warm water and a large quantity of very sour, dark, and offensive fluid, mixed with mucus, evacuated. After the hot water, a solution of boric acid and bicarbonate of sodium, eight grains of each to the ounce, was injected and again evacuated. The patient experienced immediate relief from the nausea, and the procedure was repeated daily until January 12th, the day of operation. As the diagnosis was not doubtful, the examination for hydrochloric acid was not made. The temperature during the time of his stay in the hospital previous to the operation ranged high, from 99.5° to 100.5° F. His pulse was steady at about 90 per minute. His bowels had been costive, but were made to act by enemata, and rectal injections of bovine and brandy were given three times a day to supply the much-needed nutriment.

"There were present at the operation Dr. H. O. Walker, Dr. F. W. Robbins, Dr. Pilcher, Dr. Irving, Dr. Monaghan, Mr. P. M. Hickey, Mr. A. J. Warren, and others. An incision was begun four centimetres above the navel, in the median line, and extended transversely to the left for a distance of four inches. The pylorus was found to be, as expected, the seat of a large tumor, adherent to the liver and absolutely immovable. Excision was out of the question, and I proceeded to make an anastomosis with the small intestine. I tried first to find the jejunum by grasping it at its origin, but failed to do so, and then followed Lucke's advice and grasped the highest coil of small intestine. As will appear later, I had cause to regret this part of the operation. The omentum was very thin, atrophied, and destitute of fat, and was pushed to the left. A small opening through its right border enabled me to bring the stomach into contact with the intestine, which was then sewed fast to it by six Lembert sutures in a line about four centimetres in length. A long worsted needle, armed with a long rubber cord, was then passed into and out of the stomach, the included space being about three and a half centimetres in length. It was then carried in like manner through the intestine and the ligature tied tightly and

firmly in a square knot. The ends of the ligature, which were cut short, were then secured by tying them together with a silk thread, which had been passed under them, and six Lembert sutures were inserted above. The stomach and intestine were thus fastened together by two rows of Lembert sutures and by the rubber ligature which was between them and hidden from view, while the walls of the viscera were held by the ligatures as in an ever-tightening vise. The operation of anastomosis was conducted in this case very deliberately, and consumed, after the exposure of the stomach, eleven minutes of time. The most of this was occupied in passing the fine needle armed with the silk thread through the rubber in order to secure its ends. This is quite a delicate matter, as the needle must be passed directly through the middle of the stretched rubber, in order not to cut and weaken it, as it would do if passed too near its edge. Since adopting the suggestion of Mr. Hickey and securing the knot by tying the silk thread firmly around it, I have been able to materially reduce the time required for the procedure, and can now do it on the dog in less than three minutes.

"The peritonæum, fascia and muscles, and skin were sutured separately, and the wound dressed with usual regard for asepsis. The patient reacted well and was given injections of bovine and brandy every six hours.

"January 13th.—Injections continued. Temperature as before the operation, ranging from 99.5° to 100.5° F. Pulse was stronger than before the operation. Patient had a tendency to slight hacking cough, no nausea nor vomiting; nothing was given by the mouth.

"January 14th.—No pain, tenderness, nausea, nor tympanites. Injections of bovine, brandy, and tincture of opium every four hours; mouth and tongue moistened with water, but no food nor drink. Morning temperature 100.5° F.; evening temperature 103.8° F. Ten grains of quinine in half an ounce of whiskey were given by the mouth and retained.

"January 15th.—Morning temperature 101° F.; evening temperature 100° F.; pulse 90 and good, but patient felt very weak. The mouth and throat were dry and the cough troublesome. No expectoration, negative results on auscultation and percussion, complained of acidity. Is given teaspoonful doses of wine and water every fifteen minutes. For the first and only time since the operation, the patient vomited a mucus mixed with wine and water; the stomach was washed out with the boric-acid solution.

"January 16th.—Morning temperature 100° F.; evening temperature 101° F. Patient retained milk, bovine, and wine in small quantities. Bowels moved at noon. The stool was thin, dark-colored, and offensive. Ligature could not be found, wound was dressed for the first time and found to have healed by first intention. Bowels moved three times on the night of January 16th and January 17th. Nutrient enemata altogether discontinued; patient is weak and very homesick, and complains bitterly of his cough. Bismuth and saccharated pepsin, aa gr. v, were given every three hours. Morning temperature 99.5° F.; evening temperature 100° F.

"January 17th.—Patient seems brighter and stronger. Pulse 90, good. Morning temperature 99° F.; evening temperature 100° F. Milk, beef tea, and brandy are taken by the mouth and retained; no nausea nor distress. Cough is troublesome; bowels moved five times during the day; stitches were removed from wound, which was entirely healed. The pyloric lump seems to have decreased in size.

"January 18th.—Morning temperature 99° F.; evening temperature 100.5° F. The cough is very annoying,

but sounds are clear over both lungs. The cough is aggravated by drinking, but not by swallowing solids. He ate baked potatoes and soft-boiled egg for breakfast, also some milk toast, but is dejected and homesick. Bowels moved six times since previous evening. The passages were dark and offensive.

"January 19th.—Morning temperature 99° F.; evening temperature 100° F.; cough much worse, but no expectoration. Mouth and throat are very dry. The throat is red, but not swollen, and is covered with a white deposit, which, however, may be easily wiped off. Has difficulty in swallowing liquids, but can take solids with ease. Throat was gargled with boric-acid solution. Internally, tinctura ferri chloridi, in five-drop doses. Bowels have moved seven times since last evening.

"January 20th.—Morning and evening temperature 100° F. Patient is growing weaker and more homesick. Pulse 90, good; mouth is not quite so dry, and throat is somewhat better. The pyloric tumor has apparently disappeared. Diarrhœa continues. Twelve passages in the last twenty-four hours.

"January 21st.—No material change.

"January 22d.—Diarrhœa continues, and patient is growing weaker, but otherwise no marked change.

"January 25th.—The patient insisted on going to his home, twelve miles in the country, where he died on January 27th, fifteen days after the operation.

"On January 28th I drove out with an assistant, and succeeded in getting permission to examine the abdomen. It was found that the healing had taken place with absolute asepsis, the wound was firmly and completely united. There was no inflammatory exudate whatever in the abdominal cavity. The viscera all had their normal appearance except at the seat of disease. There was a pyloric tumor as large as a hen's egg firmly adherent to the under surfaces of the liver. In the mesentery underneath there were numerous enlarged lymphatic glands. The stomach and underlying intestines were adherent by what may be called primary adhesion; that is, their surfaces were attached without any apparent deposit of lymph. I had feared, on watching the case, that I might have made the anastomosis too near the ileocecal valve, and in order to determine the exact position of the operation I was obliged to separate the stomach from the surrounding mass. I found that the seat of anastomosis in the small intestine was about 91 centimetres (three feet) from the colon. The intestine above that point was empty; below it, full of partly digested food. The cause of death was evidently inanition. In tracing out the intestine I unfortunately tore it partly apart from the stomach and thus spoiled the specimen. I found, however, that the anastomosis had been complete. In the stomach there were two holes through the mucous membrane and one through the muscular and serous coats. It was evident that in passing the needle into the stomach I had passed it too near the wall of that organ, and instead of clearing the mucous coat had pierced it, altogether, in four places, which made, on the completion of the anastomosis, two holes. This seemed to cause no difficulty in the passage of food, but it taught me to enter the needle, in the future, into and to pass it out of the stomach more perpendicularly to the surface. In this way all such complications may be avoided. The orifices in the intestine and serous and muscular coats of the stomach were three and a half centimetres (one and a half inch) long. That in the mucous coat of the stomach was, as I have said, divided in two by a small bridge of mucous membrane. It must be observed that neither in the stomach nor intestine nor

peritoneal cavity was there the slightest appearance of inflammation. The edges of the opening between the cavities were healed and the mucous membrane of the small intestine was turned around the edge of the orifice and attached. The mucous membrane of the stomach, owing to the faulty course of the needle through it, was stretched over the orifice and communicated with it by means of the two openings.

"Although in transcribing this history I have not taken up space in relating unnecessary details of treatment, having given only the essential points, enough is nevertheless given to show conclusively that it is entirely practicable to produce intestinal anastomosis on the human subject by the elastic ligature. The failure of the operation was due, not to the method of making the anastomosis, which was highly successful, but to the misfortune of establishing it too low down in the ileum for the purpose of nutrition."

In the fall of 1891 I operated again, on a woman, a patient of Dr. Flintermann's. She had refused the operation until nearly moribund, and died a few hours after it was done. A post-mortem examination could not be obtained, and the case affords no data on which we may base an opinion as regards the value of the operation.

It was about this time that I became acquainted with the Murphy button and began to operate almost exclusively by its use. No further efforts to produce intestinal anastomosis by ligature took place, to my knowledge, until 1898, when a Russian surgeon by the name of Podres made some experiments to this end by connecting the viscera together with silk threads. Sokoloff, in Moscow, operated upon four persons by Podres's method. On two of the four the operations were successful. It was found on postmortem examination of the other two that there had taken place no anastomosis, the threads having failed to cut through. Later, Modlinski read a paper at the Twenty-eighth German Congress, in which he advocated the use of a rubber, instead of a silk, ligature, and Professor Trezebicky, in Cracow, put this advice into practical operation on one patient, but failed in producing an anastomosis. This experience was published in the *Centralblatt für Chirurgie* of May 20, 1899. It is rather odd that the technique in all these operations, including those of Bardenheuer, was very similar, and was faulty in the same direction.

Instead of grasping a large area of tissue in one bold ligature, the operator sought to accomplish the purpose by a number of short ligatures, each including only from one to two centimetres. I could not learn, from the meagre description I have been able to find of these efforts, what kind of ligature was used, whether small or large, round or flat, hard or soft. And yet these matters are very important if we would achieve success by this method. I have never yet been disappointed in forming an anastomosis by the elastic ligature in the dogs upon which I experimented, and in three men, who lived for a sufficient time after the operation, and I do not believe that there will ever be a failure of the ligature to do its work, if

made of the right material and of the right shape, and if it is properly applied.

I think that, if the ligature which I have described were tied tightly around the finger and left *in situ* a week, it would cut the finger off. In my first operation on the human subject I included in the ligature a length of about three centimetres. In my later operations, which I will presently report, I included in the ligature a length of five or six centimetres. This was done for two reasons: First, to make a larger opening, and thus preclude the danger of subsequent contraction, and, second, because I have become convinced that the more tissue is included in the ligature the quicker and more certainly does it cut through.

I have, since October 1, 1900, operated in three cases of cancer of the pylorus by gastro-enterostomy.

The first was that of Mr. D., a lumber merchant, who had suffered for several months with symptoms of increasing pyloric stenosis. Dr. Chapoton, his physician, had made frequent examinations of the contents of the stomach, and found an invariable absence of hydrochloric acid and presence of lactic acid. He consulted me first, at Dr. Chapoton's request, on July 11, 1900. He complained of frequent vomitings, dyspepsia, loss of appetite, and loss of weight. An ill-defined tumor could be felt in the abdomen to the right of the navel. The stomach was dilated. He could not at that time make up his mind to an operation, the more especially because when limited to a liquid diet he could be made pretty comfortable. He continued to transact business until he became convinced of the necessity of speedy relief. On October 1st he entered St. Mary's Hospital for an operation. At the request of his family, I explained his condition fully to him and gave him his choice between the radical and more dangerous operation of complete removal of the tumor and a gastro-enterostomy, with a possible survival of one or two years. He chose the less dangerous operation. This was done on October 2d; the usual preparations were made at 8.30 A. M., the stomach was thoroughly washed out with borated water. At 9.30 I made a transverse incision, beginning at a point in the median line, about three centimetres above the navel, and extending ten centimetres to the left. Examination of the pylorus discovered a firm tumor about as large as a hen's egg, movable and free. There were a few small glands enlarged underneath it. It was a good case for excision, and I should have performed the radical operation had I not promised the patient definitely to limit myself to the other. Bringing then the jejunum up in front of the colon, I made a posterior gastro-enterostomy with an elastic ligature. The posterior wall of the stomach was first sutured to the jejunum for a distance of six centimetres by a row of interrupted silk sutures. The posterior wall of the stomach was then folded between the thumb and fingers of the left hand so that the ridge of the fold was at right angles to its long axis. A long, straight needle, armed with an elastic cord, was passed through the base of the fold, during which process the cord, for its more easy passage, was stretched and rendered taut. When the fold was released the cord perforated the posterior wall of the stomach in a line parallel to its long axis with a distance between the two orifices of five centimetres. The jejunum was then treated in the same manner. Now before noting the cord, a silk thread was laid directly under

the place where the knot would come. The elastic cord was then drawn together in one knot with such force as to compress the walls of the viscera into close folds, and the silk thread tied over it to fasten it. A second knot of the cord and a second binding of the thread fastened the ligature so firmly together that there could be no question of its slipping. A second row of Lembert sutures now completed the operation on the viscera.

The wound healed by first intention; on the evening of Tuesday, October 2d, the day of the operation, he vomited a greenish fluid tinged with blood. This was the only time that his stomach seemed disturbed during the whole course of his postoperative sickness. His temperature on the evening of October 2d was 99.8° F., and again, on October 6th, it rose to 100.2° F. At all other times it was normal. On the afternoon of Thursday, October 4th, he indulged himself with a smoke, and I permitted him to take water by the mouth. He was nourished by nutrient enemata solely during the first three days. At the close of the third day he began to take both by the mouth, and the last nutrient enema was given at the end of the fourth day. After that he was nourished solely by the mouth.

His convalescence was uninterrupted, and on October 18th, sixteen days after the operation, he left the hospital well and strong and with a good appetite and unailing digestion. He is now, on December 3d, two months after the gastro-enterostomy, attending to his business and apparently well.

The second case was that of a hospital patient, a German, aged fifty-eight years. He had suffered with digestive troubles for the last three years. In the hospital he came under the care of Dr. Steinbrecher, who made repeated examinations of stomach contents. At all times he found an absence of hydrochloric acid and presence of lactic acid. His stomach was enormously dilated. He was transferred to the surgical ward, and I operated on him on October 24th. He took the anæsthetic badly, and after the operation never regained complete consciousness. He died in collapse three hours after the completion of the operation. A post-mortem revealed a clean abdominal cavity, an enormous stomach, a cancerous tumor of large size, which was adherent to the spine and involved the lower surface of the liver and the transverse colon. The serous surfaces at the point of ligature were slightly agglutinated, otherwise there was no change. The death of this man had no connection with the mode of operation, and would doubtless have occurred had the Murphy button or any other method been used.

The third is a very important one, as it enabled me to verify by a post-mortem examination the condition thirteen days after the operation.

A Canadian, aged thirty-one years, was brought to me on October 12, 1900, by Dr. Bryan, of Essex, Ontario, with evidence of pyloric stenosis. His family history was bad. One sister had died of some malignant disease of the bowels, and another was said to have cancer of the stomach at the present time. He had suffered with dyspeptic symptoms since early in June. Indigestion was soon followed by a daily vomiting, from which he could get only partial relief by the use of a stomach-pump. A tumor was to be felt to the right of the umbilicus, and the stomach was evidently enlarged. I urged an immediate operation. This he declined, and it was not until a month later that he came again with mind made up for an operation. He had by that time become greatly emaciated, and was so exhausted that he could hardly stand. He entered the hospital, and the contents of his stomach were carefully examined. There was an absence

of hydrochloric acid. I operated on November 14, 1900. The operation of gastro-enterostomy was made with the elastic ligature, as already described.

He was given afterward, every six hours, nutritive enemata, containing peptonized milk and clear beef soup. Nothing was given by the stomach until the evening of November 17th, when we began to feed him with clear beef soup. During these three days he had been gaining in strength, but had some fever, his temperature rising, on November 16th, as high as 101° F. As he had had some fever before admission, I was inclined to attribute this to starvation. On November 18th his temperature became normal. He was given broth, milk, and other semi-liquid nourishment until the evening of November 20th, and seemed to thrive. At 11 P. M. of November 20th he was seized with severe abdominal pain and became bloated. This was attributed to over-feeding, and the amount of nutriment was diminished.

The pain and disturbance, however, continued through November 21st, although he had had some free evacuations of the bowels. On November 22d, in the evening, he vomited for the first time after the operation, a thick, yellow fluid.

Food by the mouth was now discontinued and nutritive enemata were given every six hours as before. His pain now subsided and he became comfortable again. On November 24th he was given some gruel by the mouth, with no bad effect, and we began again to give him small quantities of milk.

He manifested no pain until November 26th, when the bloating and pain began again and he began to hicough. I became now suspicious of the occurrence of a "vicious circle," but, as his pulse seemed to be gaining in volume and strength and I was not quite sure of my diagnosis, I deferred operative procedures. On the evening of November 27th he vomited once freely, but his pulse, 104 in the minute, was good, and I postponed interference until the following morning, to find then that he had suddenly collapsed and died at 4.40 A. M.

This was my first case of a "vicious circle" after gastro-enterostomy, and I did not interfere so promptly as I should have done had I not cherished the vain hope that the trouble might finally right itself. I made a hurried postmortem and found a clean and blameless peritonæum without a morbid adhesion except where the hard cancerous tumor was grown fast to the surrounding structures. There was a perfect anastomosis, but the duodenum and stomach were both distended with liquids.

I am convinced that in this case the sad result was caused by making the union too near the duodenum, for I found that the efferent limb of the jejunum exerted a decided traction on the stomach. Further examination showed a most perfect union at the seat of operation. There was a large orifice five centimetres in length. The mucous membrane of the stomach passed without a break into that of the gut. The serous membranes surrounding the orifice were adherent in a ring of about half a centimetre in width.

Of the five persons on whom I have operated by this method, two died in collapse a few hours after the operation, two of the three others lived, one fifteen and the other fourteen days after the operation, the one dying from starvation due to the anastomosis having been lo-

cated too near the ileocæcal valve, and the other from the formation of the "vicious circle." The third feels in perfect health, unconscious of the disease which sooner or later will end his life.

I regret very much that I should have put the elastic ligature aside for the Murphy button. Its one disadvantage, the length of time occupied in the formation of the opening, was, as I have said, exaggerated in my mind by my experience with dogs, in which four or five days are occupied in completing the anastomosis. It is, as yet, uncertain how long the thinner human intestine will resist the cutting action of the ligature, but it is my belief that a sufficiently large opening of communication between the viscera would exist toward the close of the second day to permit the passage of water and clear soups. In the mean time nutriment may be conveyed to the patient by means of nutrient enemata.

If the disadvantage caused by its slow action is put aside, the method is superior to all others in simplicity, ease, and rapidity of execution, and safety. There is, with this method, no possibility of complications such as arise when the openings in the stomach and bowel are of different lengths.

Three minutes suffice to put in the Lembert sutures and accomplish the function. Time is given for the serous membranes to become agglutinated before there can be a possibility of infection from the escape of intestinal contents. When it accomplishes its purpose the small contracted rubber cord passes away unremarked in the fæces.

One peculiarity in its application I have noticed which I have not been able to explain. When first applied, the stomach and bowel are corrugated in folds. At the end of twenty-four or forty-eight hours, before the cord has begun, apparently, to cut through the bridge of tissue, the folds have disappeared. I have been surprised, too, at the almost total absence of colicky pain, which *a priori* might have been expected from the severe pinching to which the gut is subjected. The pain complained of by patients is that common to all laparotomies, viz., the soreness of the abdomen.

It would be absurd to be at all dogmatic from so limited an experience. If I venture to state strongly my own hopes, and I may even say convictions, on the subject, it is because I wish a fair trial for a method which has, as I believe, unusual merits. It is adapted for producing anastomosis between all hollow abdominal viscera, except the gall-bladder, although I have as yet applied it to gastro-enterostomy only. I wish to emphasize the necessity of a proper technique as regards:

1. The ligature. This should not be a rubber thread nor a flat band; these lack the necessary strength to cut their way with certainty through the thick walls of the stomach. The surgeon must use a hard, round, smooth, and strong rubber cord, at least two millimetres in diameter.

2. It must include in one loop all of the tissue which it

is desirable to sever. The formation of several small connected loops is an error. In general, the larger the amount of tissue included in the loop the quicker and more certainly will the ligature perform its work.

3. The cord must be drawn as firmly and tightly together as possible, and fastened by a silk thread, which is tied around them. I have myself tied the rubber first in a single knot, fastened the silk around it, and then repeated the process for the sake of greater security. This may not be necessary, as the knotting of the silk thread once would probably serve the purpose.

4. Before inserting the rubber ligature the viscera should be joined together by a row of Lembert sutures for a distance of six or seven centimetres, and when the ligature has been tied a similar row in the front should complete the function. If ever there should be an ill success with the ligature, it will, I believe, occur from its too rapid action. The failures to cut through observed by certain German surgeons have, as I have said, been due to some fault in the technique.

I wish again to urge upon American surgeons the trial of this method. I firmly believe that he who has learned once to use it will never abandon it for any other procedure.

Note.—The term "vicious circle" is applied by German surgeons to a condition, sometimes occurring after gastro-enterostomy, in which the food passes from the stomach into the afferent instead of the efferent limb of the intestine. It then fills the duodenum, soon to regurgitate and pass again into the stomach. The causes of this condition are not well understood. If not relieved, it causes the death of the patient.

CEREALS, EMULSIONS, AND PROTEIDS IN INFANT FEEDING.*

BY T. M. ROTCH, M. D.,

BOSTON,

PROFESSOR OF DISEASES OF CHILDREN, HARVARD UNIVERSITY.

IN the *Jahrbuch für Kinderheilkunde* for September 5, 1900, appears a report of the proceedings of the Thirteenth International Medical Congress, held in Paris last August. The first subject discussed was entitled *Die künstliche Ernährung des Säuglings*. The opening address on this subject was made by one whom we all honor and respect, our adopted citizen, one who has been for half a century in the foremost ranks of intellectual medical progress in this country, one whose writings and personality are known and felt throughout the world, and whom we, as American physicians, are proud to acknowledge as our teacher and leader in the many questions connected with American medicine, and especially with all connected with pædiatrics.

Dr. Jacobi's views on infant feeding, enunciated some forty years ago, reiterated in Paris and at the last meet-

*Read before the New York Academy of Medicine, October 18, 1900.

ing of the New York Academy of Medicine, are well known to us American physicians; have been listened to with respect, have been studied with the interest ever connected with Dr. Jacobi's name, and have been weighed in the balance under the light of modern research, and by the aid of American methods. There is no need, then, to repeat what Dr. Jacobi has said, for it has been for years as well known as Dr. Jacobi himself, whose opinions I for one have always considered with the greatest respect, though I may not always have agreed with them. Following Dr. Jacobi's remarks are reported the views of pædiatrists well known throughout Europe, and as we read these views we are immediately struck not only with the apparent lack of knowledge of the practical investigations which have been made and the practical work which has been done in America during the last six, seven, or even ten years, but also with the fact that they pay no attention whatever to, and seemingly do not even understand, what Dr. Jacobi is referring to when, as a representative of American thought, he is reported as mentioning the American idea of percentage feeding.

Variot, Escherich, and Sevestre enunciate old ideas which American physicians now look upon as relics of the past. For instance, Variot and Sevestre still seem proud that they are able to in certain cases rear human infants on whole cow's milk. Again, Marfan disagrees with the only approach to modern methods which appears in the report of the Congress, and which was stated by Monti when he spoke of whey, but Monti does not seem to attempt to go on with the good work which he began so many years ago, simply because he does not know that his students and admirers of former years are working on his own lines.

The three points connected with infant feeding which I have been asked to speak of to-night, *Cereals, Emulsions, Proteids*, are of very great interest and importance when we wish to compare a substitute for human breast milk. It has so happened that within the last four months I have had unusual opportunities for the study of certain points connected with these questions in substitute feeding. These investigations and results are too extensive to formulate as I would wish, but will appear later in a paper on this subject which will be published by Dr. Franklin White and Dr. Maynard Ladd, of Boston, who have, under my supervision and direction, done some thorough and excellent work in connection with the treatment of milk mixtures with cereals, lime water, plain water, and whey in connection with the subject of milk modification.

I can only, in the time allotted to me to-night, outline the deductions which can be made from these investigations, and from certain clinical work which I have myself carried out with the same materials and under the same conditions as their experiments represent.

CEREALS.—The addition of cereals to the milk is chiefly for one of two reasons: First, that the resulting food should have a greater nutritive value from the ad-

ministration of starch in addition to the chief elements constituting human milk, namely, fats, milk-sugar and proteids. (The question of the use of mineral matter will not be taken up here, as it is not significant to the present discussion.) Second, to aid in the digestion of the proteids, by acting in some mechanical way on the coagulum of the caseinogen so as to render it finer and more closely to approximate the coagulum of human milk. Having once admitted that good milk as a food for infants is unrivaled by any preparation whatever, both from its nutritive and digestive qualities, it is very evident from a nutritive point of view that it is not consistent and is irrational to add an element, such as starch, which never exists in milk, except as a foreign element, and has been proved by Nature to be absolutely unnecessary for nutrition in the first year of life. If, on the contrary, starch is introduced into the milk for digestive purposes, it is supposed to act chiefly, so far as I can learn from those who believe in adding starch to an infant's food, by mechanically rendering the proteids more digestible. This brings us to the question of the mechanical subdivision of the caseinogen coagulum. In order to determine the relative value of adding a cereal diluent in preference to water or lime water or whey, or whether there was any difference in milk mixtures when centrifugal or gravity creams were used, the experiments just alluded to of Dr. White and of Dr. Ladd were made. Rennet and dilute hydrochloric acid were used in very much the same way as have appeared in the experiments of Dr. Chapin and others. The cereal diluent used was barley water, as representing the favorite cereal used by the exponents of those who have adopted the ideas of Dr. Jacobi in respect to barley water. Actual experiments, however, show that there is no difference in the action of the different cereals as diluents if they are all diluted alike, therefore Hcubner's preference for a rice diluent does not seem to be of any more significance than Jacobi's for barley water. To obtain the best results the minimum amount of starch should be about 0.7 per cent., and there is no increase in the value of barley water as a diluent when a higher percentage is used.

White's experiments also showed that the employment of a dextrinized starch solution did not appear as a diluent to differ essentially from solutions of milk sugar (lactose) or plain water, and that barley water as a diluent gave a finer coagulum than lime water or plain water.

The more the starch is dextrinized the less is its action on the coagulum of the caseinogen.

Provisional Experiments of Dr. White and Dr. Ladd on Cereals.—A milk modification of fat 3.50 per cent., milk sugar 6.00 per cent., and proteid 1.00 per cent., in which the water had been replaced by barley water, was compared with similar percentage mixtures made up of gravity 16-per-cent. cream, and centrifugal 16-per-cent. cream. The results of their observation showed that the barley-water mixture differed from the other mixtures in

that they gave a slightly finer coagulum with hydrochloric acid and rennin, and with the combination of hydrochloric acid and rennin. The barley-water mixture with lime water gave finer coagula than the barley water without lime water. No difference, however, was noted macroscopically or microscopically between the emulsion in the barley-water mixture and in the plain-milk mixtures.

In the light of the present advanced knowledge of the management of the proteids, which will be spoken of presently, we are so independent of this crude means of making a coagulum slightly finer by cereals that it would seem manifestly unnecessary to make use of such means, and entirely foreign to the information which we have received in recent years from physiological chemistry relating to the composition of the total proteids of human milk in comparison with those of cow's milk. My conclusions in regard to the addition of cereals to cow's milk for young infants are that such addition is unnecessary, because better results can be obtained by newer methods, and irrational as it differs so much from Nature's method. These conclusions are supported by a large clinical experience and an opportunity to investigate this question by exact laboratory methods.

EMULSIONS.—In a certain proportion of cases where cream is mixed with milk, water, and lime water, the emulsion seems to be at times partially disturbed, as evidenced by coalesced fat globules floating on top of the milk in the tubes. Much has been said against this condition by those who believe that such a disturbance of the emulsion contraindicates the general principle of percentage feeding. These same opponents of percentage feeding bring forward certain theoretical explanations, such as the use of centrifugal rather than of gravity cream, and other causes which are purely hypothetical, and which they have never proved to be the real cause. The investigations which I have had made included also the endeavor to solve the question of disturbed emulsion, and are as follows:

Provisional Report of White and Ladd on the Emulsion in Mixtures of Milk.—Modifications of milk giving a fat 3.50, milk sugar 6.00, and proteids 1.00 were used, and also whole milk without lime water and with lime water, heated and unheated.

The modified milk was arranged in two series, one of which was made from a 16-per-cent. gravity cream and the other from a 16-per-cent. centrifugal cream. In each series there were four bottles, two of which contained 5-per-cent. lime water, one of which was heated and the other not heated; of the two remaining bottles, which contained no lime water, one was heated and the other not heated. These specimens of milk were examined soon after bottling; again after they had been carted about the city for from eight to eleven hours, and again twelve hours after they had been delivered and had been set, one series in a warm place, and the other series in a cool place. As a result of these experiments, White and Ladd

have shown that under the above-mentioned varied conditions in no case were there any fat globules noted such as have been observed at times. Moreover, they noticed the much greater frequency of such appearances in hot weather, and did not notice them on cold days when the milk was kept under the proper conditions of temperature. The macroscopic and microscopic appearances of the centrifugal-cream mixtures and gravity-cream mixtures were essentially the same as regards their emulsion, and their reaction to dilute hydrochloric acid and to rennin and to hydrochloric acid and rennin combined. In both series the milks which were pasteurized gave slightly finer coagula than the milks which had not been heated. The fat globules under the microscope showed essentially as fine a subdivision as in an unmodified milk.

The results show that in a majority of cases there was no disturbance whatever in the emulsion in any of the mixtures, and that there was no difference in the emulsions when centrifugal or gravity cream was used. The deductions were that the disturbance of the emulsion occurred seldom under any of the above-mentioned conditions excepting in warm weather combined with much transportation, when it occurred quite frequently, and also that there must be a combination of the motion of transit with heat to produce it.

My present views on this subject are that in my experience, with milk carefully modified in the laboratories, I have of course many times met with this disturbance of the emulsion, and I have never been able to see that it did any special harm, as only part of the emulsion, and a small part, is disturbed, at any rate. Of course it is better to obviate all disturbance, but it has for years been very evident to me that the most vigorous outcries against the disturbed emulsion come from those who have had the least experience with large numbers of milks carefully modified in the milk laboratories, and not from those who by much use of the laboratories appreciate their value as practical, scientific, and exact time-savers to both physician and infant.

PROTEIDS.—The management of the proteids in an infant's food is important. Up to within the last two months it has been customary, when prescribing for a desired percentage of the proteids, to write for the total amount of proteids. This, as was pointed out to me by Dr. Westcott, of Philadelphia, is not a rational way of dealing with the proteids, for it is no wonder that when we prescribe the same total proteids in cow's milk as exists in human milk, the coagulum is larger in the former, for we are, under these circumstances, according to König, giving about five sixths of caseinogen instead of the third that exists in human milk. The total proteids in all milks is practically and for clinical purposes made up of caseinogen and whey proteids. According to the analysis of König the proportion of whey proteids to caseinogen in human milk is about two thirds of the former to one third of the latter, while in cow's milk it is about one sixth of the former to five sixths of the latter. If,

therefore, we wish to prescribe a total proteid of 0.75 we should, theoretically, write our prescription for whey proteids 0.50 and caseinogen 0.25. It is evident that young human beings have, as the best food provided for them, one which has a high percentage of whey proteids and a low percentage of caseinogen, while calves require a very high percentage of caseinogen and a very low one of whey proteids. An object which we should keep in view in regulating the lactation of the first twelve months of life is, in the early months, to start with the low percentage of the total proteids, and to make the composition of this low total proteid in the proportion of two thirds whey proteids and one third caseinogen. Then as the infant grows older we should not only increase its total proteids, so that in the latter part of the year it may take the high total proteids of undiluted cow's milk, but also that, at this late period of the lactation, the proportion of whey proteids to caseinogen should, as the total proteid becomes higher, gradually change from two thirds whey proteids to the one sixth contained in the total proteid of cow's milk. Following out this idea, I consulted with Mr. Waterhouse, of the Boston Milk Laboratory, as to how this method of dealing with the proteids could be carried out. We finally decided that it could be done by using whey. Hammarston's analysis of whey is as follows:

Fat	0.23 per cent.
Milk sugar	4.70 " "
Whey proteids	0.85 " "
Water (about)	93.24 " "
Lactic acid	0.33 " "
Salts	0.65 " "

By a series of calculations founded on the analysis of whey, it was then found possible to prescribe whey proteids by using whey, and to obtain the caseinogen by using milk. I then proceeded to write my prescriptions for whey proteids and caseinogen instead of for a total proteid, and requested Mr. Walker to have the laboratory prepared to receive such prescriptions. It was found, however, that it was not possible to furnish all the combinations desired and written for. This, however, may be accomplished in the future, but at present the laboratories can only put up a limited number of percentage combinations, such as I have been lately using and such as are shown in the table given on page following:

By referring to the table it will be seen that a total proteid over 1.50 per cent. cannot at present be obtained, and that the lowest percentage of caseinogen in the various percentage combinations cannot be less than 0.25, while the highest percentage of whey proteids cannot be higher than 0.75. These low percentages of the total proteid, however, are exactly what are needed for young infants or for sick infants with delicate digestion. It will be noticed, however, that we can prescribe any percentage of milk sugar in the various combinations from 4 to 7 per cent., and any percentage of fat from 1 to 4 per cent.

The results of the experiments as to the coagulability

of whey mixtures are still *sub judice*, but so far as they go they bear out the theoretical assumption that the coagula are very distinctly finer than in an ordinary modified milk (with or without barley water) of the same total proteids.

The deductions to be made from this method of treating the proteids are that the management of the coagulum depends on the management of the caseinogen, and that the coagulum will be small and fine if the caseinogen is kept down to its proper relative proportion to the whey proteids. Also that by using whey we can obtain these desired percentages of whey proteids, and that in all probability it will in the future be proved that by using whey the coagulum will be finer than that obtained from the use of barley water or any other cereal diluent. My views on this subject are of course only provisional until further trial has been made of this method, but I have clinically already used it in quite a large number of cases, and I believe that it is safe and practicable with a carefully preserved milk supply, such

as comes from the laboratory farms, to prescribe a percentage mixture which will retain its emulsion except under extraordinary circumstances of transit and heat; need not be pasteurized, except for long journeys in hot weather, and will not need to have cereals added for their mechanical action; also that a centrifugal cream no more disturbs an emulsion than a gravity cream, and therefore is preferable as about half a day fresher.

Whole milk has often been sent from the laboratory farms as far as Vienna without any pasteurization whatever, but simply sealed with paraffin, and has arrived perfectly fresh.

II.

THE INDICATIONS FOR HYSTERECTOMY AND
THE INDICATIONS FOR ABDOMINAL
SECTION AND DRAINAGE IN
PUERPERAL INFECTION.*

By H. J. BOLDT, M. D.,

NEW YORK.

I.

To those interested in the study of pathogenic germs upon which depend the ailments which we are about to consider, I would suggest the perusal of an article "Zur Untersuchung von pathogenen Organismen," by Robert Koch (*Mittheilungen aus dem kaiserlichen Gesundheitsamte*, Vol. i, pp. 1 to 48).

Although it has been proved that there are a number of varieties of streptococci, such as—*Streptococcus conglomeratus*, *Streptococcus involutus*, *Streptococcus pathogenes longus*, etc. (Fluegge, *Die Mikroorganismen*, Vol. ii, pp. 107 to 109), it has been thought best by most writers to discard the difference in kind. Streptococci have, however, been divided into three varieties according to their virulence; 1st, those which cause only local changes that soon disappear; 2d, those which are "mildly virulent"; and, 3d, those of "the highest degree of virulence," which cause death in a few days (*ibid.*, p. 113.)

"Most of the streptococci in pus, from different sources, are one species, having approximately the same morphological characters. Their different effects are due to different degrees of toxic virulence; they are always more virulent when associated with other bacteria, for example, the *Proteus* family." (George Newman, *Bacteria*, p. 301).

For the distinction of the streptococci forms, I refer to Ueber die Unterscheidung der Streptokokken, by Dr. H. Kurth (*Arbeiten aus dem kaiserl. Gesundheitsamte*, Vol. vii, p. 389, etc.)

To show the definitions for septicæmia and for py-

*Read before the New York Obstetrical Society, January 8, 1901.

æmia, and their mingling with the terms septic infection and septic intoxication, which may have a tendency to confuse some readers, I quote a number of the definitions found in recent text-books and dictionaries.

From Dorland's *Medical Dictionary*, 1900, Septicæmia, "A morbid condition due to the presence of non-specific pathogenic bacteria and their associated poisons (toxines and toxalbumins) in the blood. Also called septic infection and septæmia."

Duane's *Medical Dictionary*, 1900, "Poisoning of the blood by bacteria."

Foster's *Encyclopædic Medical Dictionary* gives several varieties, which causes confusion. Septicæmia is "a constitutional, generally acute disease * * * due to the absorption of various putrid substances into the blood." Fulminant septicæmia, "True putrefaction of the blood, as distinguished from septic infection." Lymphatic septicæmia, "in which the infecting material has entered the circulation by way of the lymphatics; it is rapid and severe in its course, and characterized by effusions into the serous cavities." Venous septicæmia, "That form in which the infection proceeds from a putrid thrombus, as in uterine phlebitis."

Cyclopædia of Medicine and Surgery, by Gould and Pyle.—"Septicæmia is an infective disorder produced by the absorption of septic micro-organisms and their ptomaines, generated in an open wound or by inflammation. There are two varieties: septic intoxication and septic infection. Septic intoxication is most generally met with in obstetric cases when a clot of blood or a portion of the retained placenta becomes putrid. This ailment is supposed to be due to the absorption of chemical poisons presumed to be ptomaines. Septic infection is due to the absorption of the ptomaines and the septic bacteria in the blood and to their subsequent proliferation."

Manual of Pathology, 3d edition, by Coplin, 1900, p. 272—"Infected thrombi are constantly throwing into the circulation bacteria or the products of bacterial life, this condition constituting what is known as septicæmia or mycosis of the blood. When the infected material contains pyogenic organisms, the emboli, lodging, give rise to abscesses; such abscesses are spoken of as pyæmic or metastatic, and the disease is known as pyæmia." Page 386.—"Commonly, the organisms active in the production of bacterial intoxications are pathogenic in the true sense of the word. It is not to be forgotten, however, that bacteria normally unable to infiltrate living tissues, and hence properly classified with non-pathogenic organisms, may pullulate in dead tissue, and may elaborate poisons the absorption of which may give rise to grave intoxication. The intoxication arising from the absorption of microbic products is known as septic intoxication, or sapræmia, and the element absorbed, the bacterial product, is termed pyrogenous."

The best definition for septicæmia is given by Coplin, under the term (p. 389) mycoses of the blood.—"In

these the bacteria are present and multiplying in the circulating blood in which their products are generated. The intensity of the septic phenomena is augmented by the greater production of the poison, and, not having even the barrier of protection afforded by the necessity of osmosis or absorption, they are enabled to engender lesions not presumed to occur, at least not to the same extent, in either sapræmia or local infection. * * * The embolic production of abscess is the essential element of pyæmia, a disease recognized by surgeons as septicæmia plus the infected emboli to which are attributed metastatic abscesses."

Green and Martin, *Pathology and Morbid Anatomy*, p. 325.—"Under sapræmia (septic intoxication) are included those forms of septic absorption which are due to the introduction of the chemical products of the organisms without the organisms themselves; and under septicæmia (septic infection) those forms due to the introduction and multiplication of the organisms within the body. Pyæmia is a term used to denote those cases of septic absorption which are characterized by the presence of septic embolism and abscesses. The three conditions are frequently associated."

Sapræmia.—"This form of septic poisoning can occur only where extensive surfaces are open to the absorption of large quantities of septic products under considerable pressure. Pure sapræmia, without any septicæmia, is rare."

Delafield and Prudden, *Pathological Anatomy and Histology*, 5th edition, p. 196.—"If from a focus of suppurative inflammation due to micro-organisms, or if from a point of entrance of micro-organisms without local reaction, the germs and their products become distributed through the body, inducing disease, the general condition is called septicæmia. If by the invasion of the body by the micro-organisms and their products new suppurative foci be established, it is now customary to designate the condition as pyæmia."

Stengel, *Pathology*, 2d ed., p. 197.—"From local suppurative foci toxic products may be absorbed into the general circulation, and a condition known as sapræmia results. The infecting bacterium itself may invade the blood-current without giving rise to any secondary collection of pus. This is termed septicæmia. When, however, the microbe is carried to various parts of the body and there gives rise to secondary suppuration, the condition is called pyæmia."

Ziegler's *Pathology*, 9th ed., p. 458.—"If the symptoms of intoxication come strongly to the fore in the disease-picture, then the infection is known as septic intoxication, as toxæmia, or as septicæmia. Preponderance of the metastatic suppuration leads to the form of disease designated as pyæmia or as bacteriæmia. If the symptoms of both these forms of infection appear together, then one speaks of the condition as a septicopyæmia or a pyoseptæmia."

Pyæmia. — Dorland: Pyæmia. — "Blood-poison of

microbic origin; septic infection due to the absorption of pyogenic germs."

Duane: "A condition of septic infection produced by the absorption of germs (especially the *Staphylococcus pyogenes aureus*) from a focus of suppuration." (Streptococci are usually found.—H. J. B.)

Foster's *Dictionary*: "A febrile disease supposed to be due to the absorption of pus or its constituents into the blood. It is sometimes associated with phlebitis or embolism. It results in the formation of secondary abscesses in the viscera, joints, and connective tissue."

Cyclopædia of Medicine and Surgery, by Gould and Pyle: "Pyæmia differs from septicæmia in this respect, that the absorption and dissemination of the poison give rise not only to general disease, but also cause the formation of secondary foci of inflammation, the so-called metastatic abscesses, that is to say, pyæmia is septicæmia combined with the formation of abscesses."

Green and Martin: "Pyæmia differs from septicæmia in that the absorption and dissemination of the poison give rise not only to a general infective disease, but also to scattered abscesses. It is always accompanied by some septicæmia.

"Secondary abscesses are of two kinds: 1. Those which follow septic embolism. 2. Those which occur without any apparent local cause."

The definition which I would favor is: Septicæmia (acute bacteriæmia) is a blood disease caused by parasitic micro-organisms invading the circulatory system from some primary seat of infection, the infection producing elements multiplying so rapidly in the blood that the patient generally succumbs within five days after the disease begins. Usually the parasitic germ is the *Streptococcus pyogenes*; other pathogenic germs may, however, be present also.

Pyæmia (chronic bacteriæmia) is likewise caused by the invasion of the system by the *Streptococcus pyogenes* alone or in conjunction with other pathogenic germs, but they disseminate from an infected thrombus. They are not diffused into the system in one large quantity, neither are they possessed with the same *foudroyant* virulence from a clinical viewpoint. The production of the abscesses found in the condition called pyæmia, upon which the pathological difference between the two conditions depends, is due to the parasitic organisms finding a resting place outside of the blood circulation, and there giving rise to abscess formation.

Let us endeavor to explain why there is such a difference in the course of the two ailments, both depending upon parasitic micro-organisms for their production. We know from animal experiments that a small quantity of some streptococci injected into the peritoneal cavity of an animal produces little or no disturbance, whereas a repetition of the injection at short intervals will cause death by septic peritonitis. It has also been proved that a large quantity of similar pathogenic germs injected at one time will cause a fatal issue rapidly.

That there is a decided difference in the virulence of streptococci no observer could deny; for instance, an incised wound of my finger had been infected with pus containing streptococci, and but slight local disturbance resulted. On the other hand, I have been infected, while operating on a woman suffering with puerperal septicæmia (acute bacteriæmia) where the denuded surface was so slight that only the epidermis was pierced, and not a fractional part of blood exuded. On that occasion the local and constitutional symptoms were very severe, resulting in a long siege of illness.

In addition to the clinical observations which have been made, there are numerous bacteriological studies supporting the assertion. I call your attention to the excellent work of Menge and Krönig (*Monatssch. f. Geburtsh. und Gynäk.*, Vol. ix, p. 703); (Stahler und Winkler, *ibid.*, p. 737); (Otto Burckhardt, *Beiträge zur Geburtsh. u. Gynäk.*, Vol. ii, p. 193).

When sepsis originates from infected thrombi, the infection elements, in my opinion, are diffused to a great extent through the lymph-channels by migration through the vessel-wall. Some micro-organisms are, however, carried by the blood into the circulation as the blood comes into contact with the thrombus. Small particles, not infrequently, are dislodged and carried by the circulation into a blood-vessel of such small calibre as to impede its farther progress; there the embolus produces a grave pathological lesion.

It is obvious that pyæmia (chronic bacteriæmia) should have a slower course than septicæmia (acute bacteriæmia), since the micro-organisms in the former are to a great extent disseminated through the medium of the slower lymph circulation and come from an infected thrombus, thus being thrown into the system in smaller quantities; whereas in septicæmia (acute bacteriæmia) they are thrown directly into the blood circulation and there multiply rapidly; as, for instance, infection with virulent parasitic germs on a fresh uterine wound.

Briefly consider the symptom "chills" in septicæmia (acute bacteriæmia) and in pyæmia (chronic bacteriæmia). We may diagnosticate that a patient has metrophlebitis if, in connection with other symptoms pointing to the uterus as being the seat of pathological changes, there is the occurrence of repeated chills about a week or more after confinement. Those chills are probably dependent upon a fresh addition of septic micro-organisms to the system. A woman with general septicæmia (acute bacteriæmia) has usually but one chill, or in some instances she may have none. The infection is intense and all at once. There is no repetition of the chill, because the rapidly propagating organisms are already in large quantity in the circulation.

I need not dwell upon the pathological differences found on autopsy between septicæmia and pyæmia; they are known to you. These differences harmonize with the manner in which the pathogenic germs are introduced into the system, and the difference in the duration be-

tween these conditions. But it is impossible to distinguish septicæmia from pyæmia by a bacteriological examination of the blood or tissues. Most authors classify these two conditions under two headings, septicæmia and pyæmia, whereas the conclusion I can draw from my observation is that they are in reality similar diseases, differing, so far as the symptoms and duration are concerned, only in this: septicæmia is an illness of short duration, while pyæmia is a similar illness, produced by like micro-organisms, of long duration. In septicæmia (acute bacteriæmia) the symptoms begin with intense severity and continue severe until death; in pyæmia (chronic bacteriæmia) there are exacerbations and remissions.

Again, the term "bacteriæmia" is more appropriate from the point of bacteriological science than those usually used, because it at once conveys to the mind the idea that the disease is caused by pathogenic germs. The term "septic infection" includes all ailments caused by micro-organisms diffused from some wound surface. I would propose, however, to limit its meaning to *local sepsis*; then there could be no misunderstanding as to what one meant when he spoke of the conditions which we are discussing to-night. Further, septicæmia, being an acute disease and of short duration, depends upon similar bacteriological matter to that of pyæmia. I would designate this ailment as acute bacteriæmia. To distinguish the ailment of longer duration, pyæmia, I would apply to the latter the term "chronic bacteriæmia."

II.

If the definition and the pathological changes of acute bacteriæmia are kept in mind, it should be evident that a surgical intervention, like extirpation of the uterus, whether performed *per abdomen* or *per vaginam*, or an abdominal section with drainage, and either with or without extirpation of the annexa, must be a futile operation. So far as my observation goes, it is a common error committed by many writers, when reporting clinical cases, that they include under "puerperal septicæmia" (acute bacteriæmia) cases of local septic infection accompanied by serious constitutional symptoms. This leads to confusion, especially when we see reports with such headlines as "Acute Puerperal Septicæmia; Laparotomy; Removal of the Annexa; Recovery"—or "Hysterectomy for Acute Puerperal Septicæmia; Recovery."

I maintain that such a result never has been and never will be achieved by the surgical interventions alluded to on patients suffering with acute bacteriæmia (puerperal septicæmia). For the cure of this, if ever we should be fortunate enough to find a remedy, we must look to a serum treatment.

My decisive assertion is verified by clinical experience. I have performed all the major operations which have been mentioned on a comparatively large number of patients, beginning eighteen years ago with abdominal section, extirpation of the annexa, and drainage of the

peritoneal cavity. I began with the operation of vaginal hysterectomy for puerperal infection in 1893; yet I have not seen a single instance of recovery from acute puerperal bacteriæmia (general puerperal septicæmia) even if operations were performed. In my opinion, the only effect from the operation on such patients has been to hasten death. I continued to do these operations for acute bacteriæmia, thinking that it might be possible to save a life, because others had maintained that they had been successful, but it is evident to me that those who made these assertions were mistaken in their view as to what acute bacteriæmia (septicæmia) was.

There is, however, no doubt that the operations alluded to in my title are indicated in the cases of some patients ill with septic infection. It is not so much the question of performing an operation as it is to know when to operate, to individualize, to realize when an operation is indicated. To advise and perform such serious operation is a most responsible position, and requires good judgment. These surgical interventions might, yes, probably would, save some patients ill with septic infection when with less heroic measures they would be doomed.

Although much scientific work has been done, especially in Germany, to bring clearness on the subject of puerperal infection as a whole, yet the question of treatment, including the indication of the operations which this paper deals with, is still clouded with much uncertainty. This is verified by the diverse therapeutic measures in vogue and is due mainly to our inability to make exact diagnoses. It cannot be doubted that different infection elements cause different symptoms, neither can it be denied that similar infection-producing elements give rise to a varying clinical picture, this depending upon the seat of the agents to which the infection is due. It may be argued that it is not possible to make an accurate diagnosis. This is true in the beginning of infection symptoms in the case of some patients, because the symptoms resemble each other frequently, but observing the patient carefully for two or three days usually allows us to come to a correct conclusion, if also other diagnostic aids are resorted to. Some patients ill with sapræmia may show such severe symptoms that they simulate acute bacteriæmia, but a short observation will usually decide the question.

Occasionally patients who suffer from toxæmia (sapræmia) may present positive indications for the removal of the organ giving rise to the infection. To illustrate, B. S. Schultze, Heilung schwerer Puerperalerkrankung durch Amputation des septisch inficirten Uteruskörpers (*Deutsche med. Wochenschrift*, 1886, No. 44.): The patient was delivered of a dead child on September 7th. The placenta did not follow, and upon traction the cord was torn off. The physician subsequently called could not reach the placenta to remove it. In the hospital it was likewise found impossible to remove it, even under full anæsthesia. She began to show symptoms from in-

fection two days after delivery, and her condition became very much worse; she had frequent chills and high temperature, so that it was evident that she would die if the cause of the infection could not be removed, especially as peritoneal irritation had begun. On September 13th a supravaginal amputation was made. The uterus bicornis was gangrenous nearly to its peritoneal covering. The placenta was decomposed. Recovery.

Albert Sippel (*Centralbl. f. Gynäk.*, Vol. xviii, p. 667) reports a case in which the placenta was removed by manual extraction, which was followed by hæmorrhage. Some placental remnants remained in the uterus. Sippel could not remove them either, because of the softened condition of the organ. The patient was extremely anæmic from the loss of blood. All treatment instituted did not better the toxic symptoms permanently, which evidently arose from a septic endometritis. Thirteen days subsequently to the delivery, supravaginal amputation was performed. Recovery.

Fehling condemned the procedure vigorously in a discussion, but, on careful perusal of the conditions existing, I must coincide with Sippel, because, from his description, I believe that an infection by septic microorganisms had been added to the infection by saprophytes, an occurrence not uncommon in sapræmia.

While it is true that an infection usually originates in the cervix, in these two instances it is clear that the cervix was not affected, and to perform a vaginal hysterectomy under such conditions, the uterine body being so soft that during the operation by the vaginal route the organ must necessarily have been mutilated, and the peritoneal cavity contaminated with the foul contents, would have been unwise.

Here, then, we have a clear indication for abdominal hysterectomy. The only question which in such instances needs discussion is that of whether supravaginal amputation with extraperitoneal treatment of the pedicle or total extirpation should be performed. I have, on former occasions, placed on record my view on this point as favoring total extirpation, because we can guard the peritoneal cavity from contamination by appropriate safeguards. This was also done by Siedentopf (*Centralbl. f. Gynäk.*, Vol. xxii, p. 92), who followed a Cæsarean section on a septic uterus with total extirpation of the organ. Recovery. This course has also been adopted by others.

W. A. Freund (*Beiträge zur Geburtsh. u. Gynäk.*, Vol. i, p. 397), in view of the thrombosis of the internal spermatic vein on the side of the placental site, in instances of chronic bacteriæmia, proposed and did hysterectomy, with excision of the thrombotic vessels, twice, both times with a fatal result. It seems to me that this is a useless procedure in instances in which blood-vessels outside of the uterus are thus affected, because the infection elements have probably found lodging in other parts of the body. He, too, is of this opinion.

The most exact and scientific contributions bearing

on the indications for extirpation of the septic puerperal uterus have been published by Prochownick (*Monatssch. f. Geburtsh. u. Gynäk.*, Vol. ix, p. 756, and *ibid.*, Vol. x, p. 14). He reports five cases in which hysterectomy was performed.

CASE I.—A criminal abortion at the third month. The products of conception were expelled completely. Rectal temperature 105°, pulse 140. The patient had three chills. The heart and lungs were normal. The urine contained some albumin. A smear preparation of blood from the index finger and expressed blood from the placenta contained many organisms, and only streptococci. Vaginal hysterectomy on the same day with clamps. One additional chill, with pulse rate of 160, but then the patient began to convalesce. In the parenchyma of the uterus numerous small abscesses were found. A wound of the uterus was not found. Pure streptococci cultures were obtained from the abscess cavities. According to the author, the infection was probably caused by an injury of the placenta with a uterine sound.

CASE II.—Premature birth (seventh month). Retention of placenta, which could not be removed because of myomata in the lower segment of the uterus. From the second day on, chills and fever. Supravaginal amputation. Slow recovery. No blood examinations were made.

CASE III.—Abortion in the third month, probably criminal. Retention of conception products, which were removed with a dull curette. Frequent chills and fever. First blood culture, negative. Cultures from interior of uterus showed only saprophytes; another blood culture, fourteen days after the abortion, showed positive results. Innumerable streptococci were found. Vaginal hysterectomy with clamps on the following day. Apparently the infection-producing process was limited to the uterus, but the chills continued, and the patient gradually sank and died thirteen days after the hysterectomy. Subsequently frequent blood cultures after the operation continued to show pure streptococci. On autopsy, the only serious lesion was found in the upper portion of the right lung, where a small metastasis containing a mixture of microorganisms was found. Serum treatment begun at the time of operation had no effect on the reduction of the number of streptococci.

CASE IV.—Abortion in the sixth week, from physical exertion. The patient was infected by her physician, who had just previously cleaned a septic uterus. Blood cultures showed streptococci. The sepsis-producing elements seemed, however, limited to the uterus. Hysterectomy with clamps; temporary improvement only. Death in thirty-six hours after the operation. (This was probably an instance of acute bacteriæmia [septicæmia], the blood showing pure cultures of streptococci shortly after infection by her physician.—B.)

CASE V.—Destruant mole in a patient aged fifty-three years. Frequent chills, but the blood cultures remained negative. The secretions from the uterus, however, showed streptococci infection. Hysterectomy with clamps. Recovery. For the details of this case see article by M. Voigt (*Monatssch. f. Geburtsh. u. Gynäk.*, Vol. ix, p. 63).

Prochownick proceeds as follows, as by information kindly furnished to me by him: "When called to see a patient seriously ill from puerperal infection, especially one who has chills, I take with me a sterile syringe, in sterile packing, three test-tubes with sterile bouillon, and

one empty sterile test-tube. The blood for the culture is taken, if at all possible, at the time of the ascending temperature curve (after the chill). The patient's arm is cleaned with soap, brush, and alcohol, then rinsed with sublimate solution. A gauze bandage soaked in sublimate solution is then wrapped around the elbow joint and left on from ten to fifteen minutes. Then moderate compression is made on the upper arm, and the surface rinsed off again with alcohol. Ten cubic centimetres of blood are aspirated from the median or basilic vein. From this two bouillon tubes are inoculated each with from 1½ to 2 cubic centimetres of blood. The third bouillon tube is retained for control purposes. The remaining blood is put into the empty tube. As soon as possible the three bouillon tubes are put into the oven. The tube containing the blood only is placed in a cool place until the serum has separated. 1. After six to eight, twelve to fourteen, and twenty-four hours, with a platinum point a smear preparation is made. 2. An agar or glycerin-agar tube is inoculated. A few times results were obtained after from six to eight hours, usually after fourteen hours. If positive results were obtained, they were usually pure streptococci cultures."

An interesting article bearing on puerperal infection and the variance in the clinical picture of streptococcus infection was written recently by M. Walthard, *Der Diplostreptococcus und seine Bedeutung für die Aetiologie der Peritonitis puerperalis (Monatssch. f. Geburtsh. und Gyn., Vol. xii, No. 6)*. He cites animal experiments and clinical observations with diplostreptococci. Because these streptococci show less tendency to chain-formation than the *Streptococcus pyogenes*, and because in bouillon cultures numerous diplococci are seen alongside of streptococci chains. Tavel has termed them diplostreptococci. Walthard's clinical observations are:

CASE I.—Diplostreptococcus infection by way of the uterine mucosa, then the tubal mucosa and peritonæum. Death fifteen days after confinement. No streptococci were found in the blood or in the lymphatics.

CASE II.—Diffuse puerperal peritonitis; puerperal uterus complicated by myofibromata. Diplostreptococcus infection. Abdominal hysterectomy; flushing with saline solution; drainage; recovery.

CASE III.—*Streptococcus pyogenes* infection. Death on the seventh day after confinement, which is alleged to have been normal, and with the possibility of contact-infection excluded. The only point of entrance found for the transversely oval streptococci (the diplostreptococcus being oblong-oval) existed in the cervix, where the laceration was covered with grayish membrane.

From a pathological viewpoint, the *Streptococcus pyogenes* invades the peritonæum through the medium of the blood-vessels and lymphatics, whereas the diplostreptococcus may leave the blood-vessels and lymphatics intact, and encroach on the peritonæum by progressing on the uterine mucosa, then the mucous membrane of the oviducts, and then the peritonæum. For the morphological and bacteriological differences between these strep-

tococci forms I refer to the original article. It is to be regretted that the author made no blood cultures from the living patients, or before operation in Case II, as suggested by Prochownick.

My own blood investigations in such cases are based entirely upon smear preparations obtained from a finger, and these were unsatisfactory. In two instances when streptococci were finally found, previous examinations having proved negative, the patients succumbed. In three successful instances, in which I based my indications for operation only on clinical conditions, the blood examinations were negative, the secretion alone showing streptococci. This I deem insufficient for a scientific report, because we know that we may find virulent micro-organisms in the uterus eight or ten days after the conception products are expelled, and yet the patient may not be seriously ill, the condition of the uterine parenchyma being such as to act as a barrier against the entrance of the micro-organisms into deeper structures.

In this connection I would say, however, that it would not, in my opinion, be just to a patient to wait always for an operation until positive evidence was found in the blood. To illustrate—in 1893, which was before I attempted blood examinations, I saw in consultation a woman who had been delivered three weeks previously. On the sixth day after delivery she had a chill followed by a temperature of 104° F. Two days later she had another chill with similar elevation of temperature. Her physician, probably fortunately for her, abstained from curetting and local treatment, relying on vaginal douches, stimulants, and quinine. The course of her illness continued with exacerbations and remissions. When seen by me she was greatly emaciated, the temperature 103° F., pulse 124 and feeble. The thoracic and abdominal viscera were normal. There was no exudate in the pelvis, but the uterus was large, boggy, and very sensitive to touch. Examination of the interior of the uterus under anæsthesia did not reveal the presence of placental tissue. Immediately after the examination the patient had another severe chill, with an elevation of the temperature to 105.8° F., pulse 156. In view of the gradual sinking of the patient, the irregular chills, the high fever, the size and consistence of the uterus, I diagnosed the condition as septic metritis, and because of the general condition of the patient, and the recognition of the fact that my examination had perhaps disseminated the germs more, as evidenced by the severe chill, high temperature, and pulse rate, I proposed hysterectomy, which was performed on the following morning. The microscopical examination of several sections of the uterus proved the diagnosis correct. The tissue of the organ tore as though it was decomposed. The result of the operation was that the patient had no more chills; the highest temperature after the operation was 101° F. She was able to retain her food, which she could not do before—in short, she made an uninterrupted recovery. Some may say that recovery would have taken place without such radical

treatment. Perhaps it would, but I doubt it, and the almost sudden change in the condition of the patient gives me reason to be satisfied with the course adopted, and I should repeat the same treatment now, even with a negative result of a blood examination, were I to meet with a similar condition.

I realize the great difficulty in answering the questions of if and when a patient may be saved by hysterectomy, and I believe it is impossible with our present knowledge to lay down absolute rules for the performance or omission of the operation. One's conscience must be the judge, but for general guidance I would suggest the following indications for hysterectomy, if it is evident that less heroic treatment is useless:

1. If, after a full-term delivery or an abortion, there are no conception products in the uterus, and the patient has fever with exacerbations, chills, and a small and frequent pulse (120 to 140 or more), if careful observation should show that the infection comes *from the uterus alone*, that organ being enlarged, and relaxed in its consistency, if there is no evidence of peritonitis, the parametria being free, if streptococci are found in the uterus, and, especially, if the blood shows the presence of pathogenic germs, as in Prochownik's patients.

2. If there are decomposition products in the uterus, as in the instances reported by Schultze, Sippel, Prochownik, Stahl, and others, which cannot be removed satisfactorily *per vaginam*; if, on doing a Cæsarean section, the uterus is found septic, then an abdominal hysterectomy is indicated.

Abdominal section with drainage is indicated in diffuse septic peritonitis when there is no evidence of an exudate in the pelvis. The annexa are to be left undisturbed unless there is some positive indication to do otherwise.

OBSERVATIONS ON THE TOXIC EFFECTS OF SOME COMMON DRUGS.

By PHILIP F. HARVEY, M. D.,

MAJOR AND SURGEON, U. S. ARMY.

The physiological distinction between a food and a drug, broadly stated, is that the former is absorbed by the lacteals after conversion into a diffusible peptone, and the latter directly by the veins in an unchanged form; that a food is further changed by a process of metabolism and excreted or stored up in a form different from its natural one, while a medicine passes through the system unchanged. It is therefore reasonable to regard a substance which resists the functional activities of the bodily organs as a body foreign to their normal use, and to believe that, even if exhibited in doses which appear to be tolerated, many such substances insensibly produce effects injurious to the organic integrity.

There is hardly any department of medicine so condite as that of the *modus operandi* of drugs. Much

it is true, has been made clear, but it contains many dark corners. Function and nutrition may be modified by the action of medicines on the protoplasm, on the enzymes, on the micro-organisms, on the blood, etc., and this modification may proceed to injury, not only by idiosyncrasy, cumulative action, etc., but by an insensible change in organic structures, due to prolonged use.

It is not my purpose, however, to enter into the scientific consideration of the mode in which drugs operate to produce their physiologic or therapeutic actions, but to indicate in a practical way some of the injurious effects which follow the protracted use, and in some instances the temporary use, of authorized doses.

There is a growing tendency toward greater conservatism in the treatment of chronic ailments by the use of drugs, and, happily, nowadays we do not see patients with necrosed inferior maxillæ, or caries of other parts of the osseous system from the excessive use of mercurial salts. But the disposition to push certain medicinal substances to and beyond their physiological tolerance is only too manifest and is sanctioned in the works of most authors.

Experience is a costly teacher, but in its school we have learned and must continue to learn our most valuable lessons. Where we make one permanent addition to our therapeutics by scientific deduction, we add dozens by practical experience.

It has repeatedly been my observation that the curative action of medicines in chronic diseases has been defeated by the harmful effects to the digestive, nervous, or circulatory system, following the administration of doses too large to be tolerated long enough to ultimately produce the slow alterative change required to cure the morbid condition. I think one of the most striking examples of this within my observation is the following case:

Miss C. applied to me for the relief of a pustular acne of the face of long standing. She was naturally a remarkably handsome girl, but considerable disfigurement of her face existed at that time, and she wore a thick veil to conceal her features. She stated that she positively could not take arsenic or mercury in any form, that many physicians had prescribed one or both for her, only to cause her great suffering, and she would not take any more of either. I told her the prescription I would give her would produce no such effect, and that she could take it for months without injury. I gave her very minute doses of the bichloride of mercury and chloride of arsenic. She had suffered from this acne for seven years, had never been benefited by arsenical or mercurial preparations before, or by any other treatment during that time, but in three months after the commencement of the treatment by minute doses she was well.

Many times we are in too great a hurry to achieve a certain end, and in consequence overload the bridge we rely on to carry us over; very much as a captain does when he marches his company in column of fours across

a weak bridge, which breaks down under the load, but which would have taken the company over safely in single file.

Hartzell (*American Journal of the Medical Sciences*, September, 1899) mentions arsenic when used in the usual doses in the treatment of psoriasis as an ætiological factor in the development of epithelial cancer. He cites eleven cases, eight of which had been under prolonged treatment by arsenic, and the direct influence of arsenic appears to be strongly indicated by the antecedent appearance of palmar and plantar keratosis, such as is now recognized as caused by the protracted use of arsenic. Reference is made to the suggestive observation of Geyer among the arsenic miners in Reichenstein, Russia, that carcinoma frequently occurs among them, having its beginning in "arsenic warts" on the fingers.

That such a grave effect actually follows the internal use of arsenic as affirmed is rendered all the more probable by the occurrence of other irritant effects now well established by observation, such as dermatitis with sensations of burning, proceeding even to pustulation; various lesions of the skin and mucous membrane, multiple neuritis simulating locomotor ataxia, nephritis, pigmentation of the skin, asthma, and vitreous opacities of the cornea.

In addition to the well-known train of symptoms following the continued or too free use of mercurials, there are others more insidious and less well known; one example of which will suffice in this connection: The mercurial treatment of syphilis in the infant is attended with serious danger to its future well-being, as it has been established by observation that mercury is apt to cause injurious effects on the enamel of the permanent teeth. It is, moreover, very doubtful if mercury at this age has the power to obviate attacks of keratitis, otitis, and other affections incident to puberty and afterward. An infant should not be put upon mercurial treatment unless called for by symptoms. (*Twentieth Century Practice*, Vol. xviii, page 381.)

I have met with persons who were so susceptible to iodoform, that a minute quantity dusted on a wound would at once bring on symptoms of general systemic poisoning. Scarlatinal rash, malaise, nervous disturbance, headache, insomnia, vomiting, and delirium are all effects which may be developed by iodoform absorption; and, more remotely, the drug is capable of causing fatty degeneration of the internal organs and œdema of the pia mater.

Bromide of potassium escapes very slowly and unchanged from the body, and may be found in all the secretions. It diminishes tissue waste and its long use renders breathing slower. Albertoni found that it decreased the excitability of the motor cells of the brain, and diminished the development of thought. The hydrochloric acid of the stomach sets bromine free, and acne, fœtid breath, drowsiness, feebleness, blunted faculties, and general torpor may follow its continued use, and

some patients are much more easily affected than others. Féré asserts that naphthol or salol will prevent acne and digestive disorder.

Iodide of potassium causes symptoms somewhat similar to the foregoing, in some patients, and Eaton reports a case in which acute iodism developed twenty hours after taking three grains (*Philadelphia Medical Journal*, October 28, 1899).

During the Spanish-American war, typhoid fever made sad havoc among our troops, especially in our home camps. I know from personal observation in some instances, and from report in others, that the exhibition of strychnine as a heart tonic became in many hospitals a routine treatment in that disease. From the effects it produced in certain patients who came under my observation as a consultant, I am of opinion that many lives were sacrificed to its injudicious use. The symptoms, in brief, presented by these cases, were excessive cardiac debility, denoted by a thready pulse, cyanosed surface, and great irregularity of action. In every instance the suspension of the strychnine sufficed to restore the heart function to a more normal condition.

The works on therapeutics of to-day class strychnine, with reference to its action on the heart, as a tonic; but Headland affirmed that it had no such action. The weight of evidence is in favor of its action as a heart stimulant up to a certain point, and such, no doubt, is the correct view. Theoretically, strychnine might be viewed as a heart sedative on account of its stimulating action on the vagus centre, but this depressing influence is overcome by the direct stimulating action on the heart muscle. Its routine or long-continued use in typhoid fever is regarded by the writer as fraught with danger, for the reason that it spurs on an organ which is undergoing a progressive weakening from the toxic assaults made upon it by the disease and hastens the advent of cardiac exhaustion. In the opinion of the writer, the long-continued use of strychnine to stimulate the heart in typhoid fever is unscientific and more prone to prove hurtful than beneficial. Hare says: "In some cases of exhaustive disease the prolonged use of full doses of strychnia may produce a talkative delirium with great peevishness, and, if the drug is continued, this condition may pass into a state of temporary insanity." It should be used only during short periods to bridge over some interval of danger.

The writer has many times seen cases in which quinine acted as a poison, with symptoms familiar to all experienced practitioners. Dr. J. D. Head reports a case* in which one eighth of a grain sufficed to cause an acute universal erythema with desquamation and headache. Dr. F. F. Simpson reported two similar cases,† one suffering general desquamation, including the nails, and the other going into collapse and recovering under stimulation; and Dr. P. F. Eaton reported a case in

**Philadelphia Medical Journal*, October 28, 1899, page 791.

†*Ibid.*

which quinine produced intense prolonged headache and insomnia.*

Some very interesting observations upon the toxic action of chloroform have been reported by Dr. Paul A. Heinick, in the *Medical Standard* for July, 1899. According to this, Heintz has proved by autopsies and experiments that chloroform inhaled for long periods produces, through a slow secondary action, pathological changes in the organs capable of causing death, one or several days after anæsthesia. He finds that the elimination of chloroform inhaled is completely effected only in about a week. The secondary action of chloroform exhausts itself in about a week also. He believes that ninety-five per cent. of air mixed with the chloroform is necessary to lessen the danger of an overdose.

It is probable that the rate of elimination has a direct bearing upon the systemic action of drugs, those passing rapidly out of the system being less prone to act injuriously than those eliminated slowly. Idiosyncrasy, degree of functional activity, and many inherited tendencies respond in their own way to the influence of drugs, and the careful practitioner will give them due consideration before putting his patients under treatment, especially in chronic diseases.

The subject is one of great interest and importance, and deserves more careful and earnest study than has hitherto been given it.

The writer, however, at present can only touch upon the main theme and embody in this brief note a few data which have fallen under his notice without special research.

ZAMBOANGA, PHILIPPINE ISLANDS.

THE TREATMENT OF INFLUENZA.†

BY W. H. THOMSON, M. D., LL. D.,

NEW YORK.

PHYSICIAN TO THE ROOSEVELT HOSPITAL.

MUCH stress was laid in former years on the doctrine of change of type in acute diseases. It was supposed among our forefathers, for example, that pneumonia was of a high sthenic type, and that the reason why vigorous antiphlogistic measures, so-called, were no longer as successful in modern practice as in previous generations, was because of a change in the type of the disease itself. A plausible support to this theory was the undoubted difference in severity from one year to another of prevailing epidemics of the exanthemata, but, on the other hand, in these affections, when the comparison is instituted over a series of years instead of between two successive seasons, it is plain that they have altered but little, if at all, from the times of their first recognition in medical literature.

A present exception to this statement, however, I think can be made out in the case of the influenza. Its

epidemic prevalence in this city and throughout the country during the past month is about as extensive as it was when it made its first invasion, in 1889-1890. But nothing is more certain than that its clinical accompaniments now are much milder, as a few illustrations from my own personal experience will suffice to show.

In 1890 numerous suicides were reported of persons attacked by the grippe, one of whom was a valued personal friend of mine and who, without the least known reason to his friends, and evidently when impelled by a very sudden impulse, threw himself out of a window. I also had four cases of sudden insanity, all delusional in character, in no case with symptoms of acute mania, and all very transient except the last, which continued for some months and gave rise to legal complications. I saw in consultation two cases of chronic meningitis with very serious sequelæ which followed influenza, and a very considerable number of cases of neuritis, both of nerve trunks and of obstinate peripheral neuritis. In one case also with chronic cerebral symptoms, accompanied by dilated pupils for several months, before recovery very extensive desquamation of the skin occurred. I also met with three cases of extraordinary acute gastritis, one of them rapidly fatal. Several cases also of the most profuse sweating that I have ever witnessed, one being that of a lady, in which it dripped from the bed upon the floor. Also several cases of acute nephritis, one in a physician which ended in chronic Bright's disease, and so on. In short, a more universal and virulent poison than this infection appeared to be on its first visitation has hardly been recorded in the annals of medicine: for, though cholera, yellow fever, and the plague have each been at times more destructive of life, yet they are always very specific and well-defined in their symptomatology according to their own special lesions, while influenza seemed to make its attack along the whole line as it listed.

My own personal experience with my first and only attack was in that epidemic, when, without any warning whatever, while I was returning in my carriage from a consultation in a case of grippe pneumonia, I felt as if a disc of iron had transfixed my temples. It was with difficulty when I got home that I reached my bed. Excruciating pains in the back and limbs, high fever, and a sense of intense prostration lasted through the night and all the next day. The catarrhal symptoms were very slight. In three days I was able to sit up, but there then followed an experience which hundreds that winter described as their own also after *la grippe*. For fully six weeks I felt as weak in my muscular system as if I had suddenly passed seventy years of age. It was not so much that I would be easily exhausted by muscular exertion as that I did not seem able to exert myself from the start, but rather seemed to have all the debility of advanced life settled upon me.

The other attendants of the influenza are familiar to all and seem due primarily to general diminution of the resisting power of the system to bacterial invasion. We

**Ibid.*

†Read before the Section of Medicine of the New York Academy of Medicine, January 15, 1901.

may, in fact, regard this lowering of vital resistance as one of the most serious results of this infection at all times. Pneumonias occurred with all the characteristics of the lobar or croupous variety, and were exceptionally fatal.

Bronchopneumonia, of course, followed suit, engrafted upon the influenzal catarrh, and carried off multitudes of the aged. Pulmonary phthisis increased to more than double its usual prevalence, and whoever had a vulnerable part in his body was very likely to have his trouble there greatly aggravated. In many a fatal case of chronic disease the beginning of the end would be very probably dated from an attack of the influenza.

On the other hand, my experience in the present epidemic has been that of meeting with very numerous cases of simple catarrhal fever, beginning as often gradually as suddenly with malaise, chilliness, coryza, and bronchitis, accompanied with the usual train of aching in the head, back, and limbs—in short, with all the characteristics of a severe old-fashioned cold, with an increased tendency to general debility. As might be expected, the most common of the serious complications are connected with the bronchi and lungs.

Now, I scarcely believe that this change in the clinical aspects of the disease is owing to any change in the character or properties of the specific bacillus which is the cause of the infection, but rather that it is due to the same kind of modification in the system of those at present attacked which a previous vaccination causes in a subsequent infection of variola. When we consider how great the number now is in any community who have had one or more attacks of the influenza since 1890, the greater the probability is that those previous attacks have rendered them less susceptible to the worst effects of the infection, so that it now develops in them in a milder form. I am the more confirmed in this inference by two cases which I have lately seen which presented the same severe constitutional conditions which were so common in the first epidemic, and both these patients had never experienced an attack of influenza before. Moreover, I am of the impression that in young children it is this year relatively more severe than in adults.

As to treatment, my own experience and sensations during my illness with this complaint led me to deal with it symptomatically somewhat on the following lines, and, as we do not yet possess either antidote or antitoxine for the poison of Pfeiffer's bacillus, we can only prescribe for its symptoms. In the first place, I have long relied upon aconite as the best remedy with which I am acquainted for the general aching which characterize the onset of so many febrile infections. Not only is it one of our most effective analgetics for this class of pains, but it counteracts the accompanying vascular derangements, particularly of the upper respiratory tract. I believe that I have often aborted an acute tonsillitis by administering early a dose of the tincture of aconite sufficient to cause this drug's specific sense of constriction in the throat. At the begin-

ning of the febrile infections, including that of croupous pneumonia, aconite has seemed to me not only to relieve the systemic pains, but to modify much for the better any local capillary stasis setting in with the onset of the fever. The heart under its influence becomes much quieter and the pulse softer; all results more than temporarily beneficial, as the subsequent course of such acute affections often appears to be better for timely dealing with the initial derangements. This particular action of aconite seems to me further promoted by the addition of a small dose of Dover's powder.

One member of the coal-tar series has also proved in my hands very serviceable in these febrile pains, and that is phenacetine, because its analgetic action, especially when combined with aconite, is more marked in influenza than in any other affection. I would not give it in influenza in doses sufficient to reduce temperature, for temperature here is a very secondary matter; and, moreover, in antipyretic doses it may have the undesirable effect of weakening muscular function, which, in the case of the heart, is to be dreaded in a gripe bronchitis or pneumonia. But, combined with quinine, it may have another action also; namely, these two drugs may not improbably act as true antitoxines to the influenza poison. There is no *a priori* reason why these blood antiseptics may not be effective as such against this infection, and only experiment can determine the question. My own experience is decidedly in favor of this hypothesis, for these combined agents have seemed to me to mitigate the symptoms and to prevent the sequelæ of the disease, evidently not by their antipyretic properties, but by a specific neutralization of its effects, as is indicated by the less favorable course of those cases in which these medicines have not been taken.

Influenced by these considerations, I devised for my own case while suffering from the gripe a prescription containing in each dose $\frac{1}{6}$ th of a grain of solid extract of aconite, 1 grain of Dover's powder, 4 grains of phenacetine, and 3 grains of quinine, made into two pills; three doses, or six pills, to be taken on the first day of the attack, and continued daily as long as a febrile temperature lasted. As soon as the temperature declines, whether on the second day or subsequently, the dose is reduced by one pill a day, till three, or one half the first daily dose, are taken, and this is continued until all catarrhal symptoms have subsided. My experience with this prescription was so uniformly favorable that I often had occasion to recommend it in consultation, with the result that by the request of different physicians the wholesale firm of the Messrs. Schieffelin & Co., in this city, have put up the prescription under the name of the compound phenacetine pill, the formula for which is printed on the labels upon the bottles. Owing, apparently, to the extensive sale of these pills, they are also manufactured by McKesson & Robbins, of this city; Upton & Co., of Kalamazoo, Michigan, and other wholesale druggists. Some patients who are very susceptible to aconite find the dose in this for-

mula causes numbness and tingling, in which case its proportion may be reduced.

When coryza and nasal catarrh are leading symptoms the peculiarity is often developed in influenza of a sudden shifting of the trouble from the nasal passages to the trachea and then back again. In such conditions a pill of a quarter of a grain of extract of belladonna with a grain or two of camphor seems to afford relief. To this should be added a flushing of the throat by a fountain or a Davidson syringe with a quart of hot water in which two teaspoonfuls of potassium chlorate and five drops of oil of peppermint are dissolved. This measure often affords a marked relief by causing a great flow of mucus from both nose and thorax with the return current from the mouth. On the other hand, a very troublesome complication occasionally occurs by the supra-orbital sinuses becoming involved, with attacks of excruciating pain and often photophobia. It is curious that these pains are very commonly periodical, commencing at a definite time in the forenoon and measurably subsiding at night. The specific for these pains is the fluid extract of ergot, in drachm doses, repeated every three hours if necessary. The addition of a drachm of elixir of cinchona makes it better borne by the stomach. I once published a paper on the use of ergot in periodical neuralgias, not necessarily confined to the head, and in 1890 I had frequent illustrations of its curative powers in these pains following influenza whose seat was sometimes in the sides of the thorax, in the abdomen, and in the sacrum or pelvis. In each case morphine hypodermically, with large doses of quinine, Warburg's tincture, etc., had been unavailingly prescribed, while the ergot afforded immediate relief.

One accompaniment, or sequel, rather, of influenza may be mentioned here, and that is the supervention of a markedly paroxysmal dry cough which has nothing to do with bronchitis, but is evidently of a nervous character and which may persist for weeks after other symptoms have subsided. It is apt to be especially troublesome at night. I have generally found it yield to doses of twenty grains of the ammonium bromide with ten of antipyrine.

In no other infection does an intercurrent bronchitis so often become serious as in influenza, particularly in patients past middle life with more or less endarteritis and habitually high-tension pulse. The course of the affection very commonly is that after a week or more of the ordinary catarrhal symptoms, the temperature rises rather suddenly from 99° to 102° or 103° F. The cough may then become less frequent but more severe when it does occur. Insomnia then may be much complained of, and the physician be disappointed at his morning call by the discouragement of his patient from passing such a bad night. He changes his remedies from day to day only to find each improvement very temporary and a bad relapse follow. After a time disquieting signs of respiratory failure develop, with the constant presence of râles

at both bases along with lessening power of expectoration. This condition calls for active treatment, and it is well to note what the chief elements in its production may be. I have long thought that the influence of the mechanical factor of unexpelled viscid mucus in the smaller bronchi has been too much overlooked in accounting for the graver symptoms in bronchitis. When we note the inevitable and peculiar pneumonia which follows the plugging of a main bronchus by a foreign body, it seems natural to infer that a like occlusion of the smaller bronchi by tough plugs of secretion will entail a local pneumonia of the same kind in the areas supplied by these bronchi, and it is the supervention of this condition which is marked, as I believe, by the new rise of temperature. This bronchopneumonia, therefore, is not by an extension of the catarrhal process itself from the bronchi to the air lobules, but rather is allied to the serious mechanical pneumonia of occlusion, which, as is well known, disorganizes the delicate structure of the air-vesicles and soon implicates the interstitial tissues with consequent frequent caseation of the inflammatory products. The chief indications for treatment, therefore, would seem to be to liquefy the retained secretions as effectively as possible, and simultaneously to stimulate the function of expectoration. It is remarkable how easily the bronchial tract is sometimes freed from contents which are really fluid, as we often note a copious bronchial hæmorrhage got rid of with so little coughing that the patient may be uncertain whether the blood came from the lungs at all. Now, I have been struck with the apparent failure of the preparations of ammonia to subserve this purpose of promoting expectoration when the inflammation has reached the smaller tubes, compared with their apparent benefit in inflammation of the trachea and larger bronchi. My own remedy, which I have often advocated for the past twenty-five years for converting a viscid bronchial secretion into a freely flowing liquid, is the emulsion of linseed oil. This emulsion is now sold extensively throughout the country as a proprietary article, and during the past year I have been in frequent receipt of other linseed emulsions made and sold as proprietary articles by druggists both in this and in other cities. All that I wish to say about it now is that I do not know of any so-called expectorant in bronchitis which equals it, as I have lately had occasion to note in consultation cases of influenza when other remedies for this purpose had been previously fully but vainly tried. I always add to each dose of the emulsion a twelfth of a grain of morphine and eight grains of chloral, simply because the nervous element of irregular bronchial muscular action is always a hindrance to efficient expectoration in bronchitis.

Adjuvants which should not by any means be neglected are, first, thorough dry cupping of the chest, both anteriorly and posteriorly. We scarcely possess a more powerful stimulant to the bronchial muscles than the peculiar reflex action of this cutaneous impression, both to restore their rhythm, as is shown by the prompt arrest of

the sibilant wheeze, and by increased power of both acts of respiration following it. We should not be afraid of repeating this application too often, but the weak cupping by glasses with rubber bulbs is wholly useless. Following the cupping, the stimulant action of large cloths applied to the surface of the chest, wet with the infusion of capsicum, made with a drachm to the pint of boiling water, is quite preferable to mustard, as it does not occasion vesication or an intractable sore. It is well to keep up such cutaneous stimulation for a long time, because the patient who has once had a bronchitis develop basal râles is not likely to cease coughing for weeks. One of my prescriptions for this purpose is a liniment of one part each of aqua ammoniæ, oleum terebinthinæ, and tincture of capsicum, with three parts of linimentum saponis. For the tedious debility which follows influenza I rely mainly on the fluid extract of coca with nux vomica. Inhalation of oxygen is also often serviceable if administered with a funnel over the nose and mouth as in administering ether. The usual method of simply holding the tube to the nostrils scarcely gives the patient any appreciable amount of the gas.

It should always be impressed upon the patient, as soon as the diagnosis of influenza is made, that he should at once go to bed and stay there till further orders. A slight attack of influenza scarcely ever means the same thing as a slight attack of illness, any more than a mild scarlatina ever means that it is really mild. A slight influenza may cost the patient his life, all the same, for we are continually meeting with cases of fatal complications developing after the most moderate beginnings of this infection. Rest in bed is quite enough for most persons to get well of influenza without any medicines, if they will only take this prescription faithfully to the end. But the majority wish to get out too soon, it may be to attend a dancing party, when they succeed in furthering the epidemic spread of an infection which is every whit as catching as measles.

Therapeutical Notes.

For Firemen's Cramp.—Willis Cummings (*Merck's Archives*, August, 1900; *Medicine*, November, 1900) considers this colic due to an excessive loss of fluids and solids, consequent on the profuse sweating, with a reflex vasomotor paralysis of the abdominal circulation and a spasmodic condition of the muscles. In a crude way he attempted to estimate this loss and to supply a water which contained a sufficient quantity of solids to supply the waste. To one gallon of water were added:

Calcium phosphate.	256 grains;
Sodium phosphate.	256 "
Potassium phosphate.	256 "

with an excess of orthophosphoric acid. Four ounces of this solution were put into nine gallons of water; to this was added some oatmeal and ice, if available. Each man was given a gallon of the acidulated water during four

hours, the phosphates in solution amounting to three and one-half drachms. After this treatment was instituted the cramps and colic immediately disappeared. The solution was very highly appreciated by the men, and it resulted in a diminution of the desire for alcoholics, so common among this class of men.

For Amenorrhœa.—The *Journal de médecine interne* for December 15th gives the following hypodermatic treatment for amenorrhœa:

℞ Crystallized apiol.	300 grains;
Sterilized oil.	1,500 "

M.

A Pravaz syringe (one cubic centimetre, or sixteen minims) daily.

A Lotion for Genital Pruritus.—A formula of Robin's is given in the *Journal de médecine de Paris* for December 9th as follows:

℞ Mercury bichloride, {	each. 1 part;
Ammonium chloride, }	
Emulsion of almonds.	2,000 parts.

M.

An Abortive Treatment of Chalazion.—Strzeminski, of Wilna (*Semaine médicale*, 1900, No. 42; *Fortschritte der Medicin*, December 19th), recommends this ointment:

℞ Iodine.	2 parts;
Potassium iodide.	6 "
Lanolin.	enough to make 75 "

M.

To be rubbed gently on the affected lid.

An Ointment for Intertrigo and Acute Eczema.—The *Journal de médecine de Paris* for December 16th gives the following formula as Wende's:

℞ Camphoric acid.	1 part;
Bismuth subnitrate, {	each. 2 parts.
Zinc carbonate, }	
Powdered starch, }	
Vaseline, }	
Anhydrous lanolin. }	

M.

Caffeine as a Cardiac Stimulant.—The *Klinisch-therapeutische Wochenschrift* for December 16th attributes this formula to Capitan:

℞ Caffeine, {	each. . . . 15 to 22 grains;
Sodium salicylate, }	
Sparteine sulphate.	6 "
Ammonium acetate.	15 "
Distilled water.	1½ ounce.

M. S. A coffeespoonful every half hour till three doses have been taken. It is said to be very prompt in its action.

Cod-liver Oil Soap in Pulmonary Consumption.—Rohden (*Deutsche medicinische Wochenschrift*, 1900, No. 39; *Fortschritte der Medicin*, December 12th) employs a superfatted soap made of cod-liver oil and an alkali, to which may be added various medicaments, such as balsam of Peru, potassium iodide, etc. It is employed by inunction on the legs, the neck, the breast, and the back, about two drachms and a half at a time. The treatment lasts for several weeks at least.

NEW YORK, SATURDAY, JANUARY 26, 1901.

FILTH AND THE SPREAD OF DISEASE IN NEW YORK.

THE recent action of a Columbia University professor in causing the arrest of a passenger in a public conveyance for spitting on the floor, an act forbidden by a board of health ordinance, has, we understand, resulted in the offender's being punished; at all events, it may be presumed to have served the good purpose of giving the public an inkling of the determination of the sanitary authorities and of all good citizens to suppress the indecent and dangerous practice of promiscuous spitting. Not only upon this vicious practice, but also upon many allied means of disseminating pathogenic germs, is a vivid light shed by Mr. Elmer W. Firth, a civil engineer and a fellow in sanitary engineering of Columbia University, in a paper entitled *Micro-organisms in the Air of Public Buildings and Conveyances, due to Improper Methods of Cleaning*, a paper submitted in partial fulfillment of the requirements for the degree of doctor of philosophy in the University Faculty of Pure Science and published in the seventh volume, recently issued, of *Studies from the Department of Pathology of the College of Physicians and Surgeons*, which, as our readers know, is the university's school of medicine.

The New York public has improved somewhat of late years in attention to the joint demands of decency and health, but Mr. Firth's examinations of specimens of air contaminated with bacteria and his descriptions of certain processes still in vogue in the so-called cleansing of buildings, street railway cars, ferry boats, and the like, show that a great task is yet to be accomplished in the direction of public cleanliness, and much of the cleaning that is now done might better go undone, for it actually adds to the spread of germs. In his summary Mr. Firth properly insists that no attempt should be made to conceal dust and dirt, as by the use of certain absorbent floor-coverings. Carpets and fibre mats should no longer

be used in churches, theatres, court rooms, street cars, and ferry boats. When a room is swept or dusted, the process should be performed several hours before it is to be occupied by an assembly, unless there can be such a draught of air completely through it as to clear out the bacteria, and this, as he points out, is hardly possible in the case of a theatre. Unless, he says, the draught can pass directly across the room, between openings on opposite sides, currents of air from open doors and windows may keep micro-organisms in suspension for an indefinite length of time. Dry sweeping and dusting should never be done in the presence of numbers of people, as is now the practice in some conveyances. The absolute removal of the solid impurities of the air, which settle in all buildings, is best accomplished by the use of damp cloths, and frequent washing or mopping of the floors is essential to proper cleanliness in public places. Dust thus moistened may be removed unobjectionably. "Finally," says Mr. Firth, "the material accumulated in cleaning should be so disposed of that it will not be merely a nuisance transferred to another place, but one absolutely suppressed."

THE LESSON OF THE ENGLISH "EPIDEMIC"
OF ARSENICAL POISONING.

It was very clearly brought out in an interesting discussion on epidemic arsenical neuritis at a meeting of the Liverpool Medical Institution held on December 20th (*Lancet*, January 5th) that, as Dr. R. J. M. Buchanan remarked, the lesson of the recent prevalence of arsenical poisoning from drinking contaminated beer was that members of the medical profession individually should cultivate the faculties of observation and deduction to the highest degree. The familiar association of alcohol and peripheral neuritis in the relation of cause and effect, he said, had no doubt tended toward incredulity regarding the statements made by patients who denied excess. "thus narrowing the field of mental vision and hindering the elucidation of the truth."

A prejudiced state of mind on the part of the medical man when confronted with a morbid condition is almost a bar, for the time being at least, to his arriving at a correct diagnosis. To elicit the salient signs and symptoms and then to say to one's self that only alcoholic indulgence, syphilis, malaria, hysteria, or some other stock aetiological agency can lie at the root of the trouble is not only to waste time which should be devoted to further investigation, but positively to bar the way to the true solution of the case. It is always well to look askance at the plausible; it so easily leads one into error. One

should cross-question his first impressions, leaving no stone unturned in an exhaustive investigation to determine, on the one hand, that there is no feature in the case incompatible with the diagnosis that seems most obvious, and, on the other, that no other hypothesis than the one tentatively entertained will cover all the points. Minor exceptions, of course, have to be allowed for, and we cannot hope to meet always or even almost always with typical pictures of disease; otherwise the art of diagnosis would be a marvel of simplicity, whereas, as we all know, it is the most difficult that the physician has to practise. It is in prognosis perhaps, as was maintained by Trousseau, that the physician's wisdom is most conspicuously shown, but it still remains true that it is in diagnostic acuteness that lies his straightest path to success in practice. The lesson is always before us; it is but emphasized by the recent extensive prevalence of arsenical poisoning in England.

THE CARE OF THE DYING.

WHEN, at the close of a naval engagement in the recent war with Spain, Captain Philip besought his men not to cheer, saying "the poor devils are dying," he gave voice to the humane feeling of all well-ordered people. To disturb the dying purposely is left to savages, to disquiet them unthinkingly is a mark of reprehensible carelessness if not of selfishness, to sooth them with all possible art and tenderness is the part of gallantry. In general terms it may be said, we think, that comparatively few dying persons are in physical pain; we doubt, indeed, if most of the dying have any feeling of dread, even when they are conscious that the end is near. Nevertheless, the assiduity with which we minister to the sick should not be relaxed—rather should it be heightened—in the case of the dying. A dying person, if conscious, is easily harassed, and often one who seems unconscious is not wholly insusceptible to impressions from without. It is said that ordinarily the sense of hearing is the last of the special senses to leave a dying person, that for a considerable time after the sight and the sense of touch are gone the power of hearing lingers; hence the caution has been given, and should always be observed, to exercise great care as to what is said at the bedside of one who seems unconscious.

Actual suffering, whether bodily or mental, is probably, as we have said, not generally felt by those who are really dying, but discomfort is apt to be present. A fold of the linen or an inequality of the bed may give rise to

real interference with composure, and that at a time when death is so close at hand that the faculty of speech is gone. The open mouth may be parched or a glare of light may offend the eyes. It is the duty of the physician, of the nurse, and of all present to be alert to do away noiselessly and unostentatiously with all these sources of annoyance. Such matters as these are wisely and humanely treated of by Brunke, of Uchtspringe (*Irrenpflege*, December; *Zeitschrift für Krankenpflege*, December), who remarks that, while the thought of approaching death is one of awe and anxiety to most persons, the conviction that it is stealing on, coupled with readiness to meet it, makes the nurse's part immeasurably easier than it otherwise would be, for she is relieved of the harrowing dread lest in an unguarded moment she may involuntarily add a sudden pang by suggesting the fatal termination.

When a dying adult person is unaware of his condition, it is sometimes, perhaps generally, the physician's duty to intimate the truth, but never should a blunt declaration of impending dissolution be made. There are few tasks that call for more tact and delicacy than the care of the dying, and it is particularly in what is said to the dying person, whether spontaneously or in answer to questions, that the humane physician and nurse best show their title to the love of their fellow-beings.

THE PASSING OF A GRACIOUS SOVEREIGN.

THERE is probably no person in the world whose fatal illness could have caused the widespread sorrow and sympathetic reverence and respect occasioned by that of Queen Victoria. The termination of her long and arduous life, which, in the ordinary course of events, could not have been long delayed, forbade us to expect much from the greatest resources of medical aid and skill at her disposal; but the efforts of those who were privileged to minister to her—privileged, not because she was a queen, but because being a queen she had been all that she was in every capacity of life—have been followed closely with the warmest prayers of the world at large in their support, and with its tenderest sympathies. For this reason the names of Sir Thomas Barlow, Sir Douglas Powell, and Sir James Reid will be preserved in history, irrespectively of their services to medical science in general, as those who cared in her last moments for the most universally beloved monarch that ever sat upon a throne. The medical profession in all countries will ever cherish the memory of a sovereign who constantly interested herself in the relief of suffering, who held medicine in high esteem, and who was the first British monarch to publicly recognize the importance of medical science by conferring a patent of nobility on a medical man.

TOBACCO AND COLOR BLINDNESS.

It is stated that one of the prominent American railway lines has, on the initiative of its medical examiner, decreed that henceforth all tobacco users shall be barred from its employ in certain capacities, because of the danger of the induction of color blindness by the habit. Of course the poor, unfortunate, and much maligned cigarette is especially damned. It is strange that probably eighty per cent. of artists are, and always have been through the present and many preceding generations, inveterate users of tobacco, till the mingled smell of paint and tobacco has become the recognized odor of the artist's painting-room. Yet we do not hear of many artists being incapacitated from their profession on that account. Is color perception, after all, not essential to the artist?

EXECUTION BY POISON.

THIS ancient fad has been revived. According to press dispatches Representative H. B. Passage moved on January 21st in the Indiana House of Representatives that the method of executing criminals be changed from hanging to administering morphine. The motion was tabled. The proposed change came up in consideration of a bill fixing the Michigan city prison as the legal place for the execution of criminals. The bill has been passed by both branches, and is now in the hands of the governor.

Hemlock is a time-honored medium for this purpose, and the reflection that Socrates suffered thereby might aid in lessening the injury to the poor criminal's sensibilities. A hybrid and barbarous name for the process will doubtless be essential. How would "toxicution" do?

REPORT OF THE SURGEON-GENERAL OF THE ARMY.

THIS report has already been noticed in our columns, so far as its more strictly medical portion is concerned, and an abstract given of its substance. The report now before us in its entirety is a further evidence of the careful scientific and administrative work of our army medical department. The vast range of inquiry embraced in it cannot but prove of incalculable value, not only to the military medical service, but to the science of medicine at large. The sections on the Division of the Philippines, the Division of Cuba, and the Department of Puerto Rico are of special interest, the former being illustrated with excellent process pictures of many of the buildings employed for hospital uses. The reports on the prevalence of various diseases are exhaustive, and show much careful work. Special notice may be taken of those on bubonic plague, by Major Guy L. Edie, and First Lieutenant W. J. Calvert, the latter of whom gives a most interesting description of the methods of dealing with plague in Japanese cities and in Hong Kong; and the report on the treatment of yellow fever, by Acting Assistant Surgeon Bat Smith. In the matter of alcoholism in the army, it

is gratifying to find the admission rate fallen to nearly one half of its rate for 1897, though still in excess of that of 1898. Commenting on the figures, the report says: "From this it will be seen that there is more drunkenness in a command doing garrison duty in time of peace than among troops on active service." This is only what might be expected.

THE DANGERS OF CELLULOID.

FROM time to time cases occur which ought to emphasize the danger of celluloid articles of wearing apparel, especially ladies' hair combs, etc. A report comes from Birmingham, Ala., of a young lady who has been seriously, perhaps fatally, burned by the ignition of her celluloid hair comb. If there were no other material available for such articles, the rarity of accident might outweigh the consideration of the dangers of this material; but considering how many things can be used to make the articles commonly made of celluloid, we can only wonder at its continued employment.

A PHARMACOLOGIST IN FICTION.

WE have been much interested in a recent book of fiction by a well-known Cincinnati pharmacologist, Professor Lloyd.* The story proper consists of the personal history of a girl of apparently illegitimate birth, who, however, turns out to have been the daughter, born in wedlock, of a prominent citizen of Kentucky, who cruelly disowns her and her mother. Left a waif on the outskirts of Stringtown, she is adopted by a fanatical and superstitious old negro, and most of the thrilling incidents of the story, and they are numerous, cluster about the imaginings of this old negro, "Cupe." She is beloved by "Sammy Drew," a stupid boy who seems to have had but one bright spot in his mind, an aptitude for chemistry; but he is a chump to the end, and it is greatly to Professor Lloyd's credit as a story-teller that almost to the very last he keeps the reader interested in so dull a character. Drew becomes a professor of chemistry, examines the gastric contents of a man supposed to have been poisoned with strychnine, finds the proper reactions, and testifies to the presence of strychnine, thereby leading to the conviction of the accused. The girl, "de Susie chile," doubts the validity of the evidence, studies chemistry herself, and eventually confronts her lover with the statement that hydrastine and morphine, mixed in proper proportions, will give the color reaction of strychnine, whereupon he commits suicide by taking a certain mysterious vegetable poison obtained from Arkansas. How far this narration will tend to intensify the present prejudice against expert testimony it is difficult to say. Possibly Professor Lloyd's object, apart from furnishing entertainment, was to discredit chemical testimony in criminal cases.

Stringtown on the Pike; a Tale of Northernmost Kentucky. By John Uri Lloyd, author of *Etidorhpa*, etc. New York: Dodd, Mead & Company, 1900.

News Items.

Society Meetings for the Coming Week:

MONDAY, January 28th: Medical Society of the County of New York; Lawrence, Massachusetts, Medical Club (private); Cambridge, Massachusetts, Society for Medical Improvement; Baltimore Medical Association.

TUESDAY, January 29th: Rome, New York, Medical Society; Boston Society of Medical Sciences (private).

WEDNESDAY, January 30th: Auburn, New York, City Medical Association; Berkshire, Massachusetts, District Medical Society (Pittsfield); Middlesex, Massachusetts, North District Medical Society (Lowell); Gloucester, New Jersey, County Medical Society (quarterly).

FRIDAY, February 1st: Practitioners' Society of New York (private); Clinical Society of the New York Post-graduate Medical School and Hospital; Baltimore Clinical Society.

SATURDAY, February 2d: Manhattan Medical and Surgical Society, New York (private); Miller's River, Massachusetts, Medical Society.

Marine-Hospital Service Health Reports:

The following cases of small-pox, yellow fever, cholera, and plague, were reported to the surgeon-general during the week ending January 19, 1901:

Small-pox—United States.

Oakland, California.....	Dec. 29-Jan. 5...	1 case.	
Bridgeport, Connecticut.....	Jan. 7.....	3 cases.	
Cairo, Illinois.....	Jan. 5.....	8 cases.	
Chicago, Illinois.....	Jan. 5-12.....	19 cases.	
Wichita, Kansas.....	Jan. 5-12.....	6 cases.	
Baltimore, Maryland.....	Jan. 5-12.....	1 case.	
Springfield, Massachusetts.....	Jan. 5-12.....	1 case.	
Minneapolis, Minnesota.....	Dec. 29-Jan. 5...	1 case.	
Winona, Minnesota.....	Dec. 29-Jan. 5...	30 cases.	
Manchester, New Hampshire.....	Jan. 5-12.....	21 cases.	
New York, New York.....	Jan. 5-12.....	17 cases.	3 deaths.
Ashtabula, Ohio.....	Jan. 5-12.....	4 cases.	
Cleveland, Ohio.....	Jan. 5-12.....	51 cases.	
Philadelphia, Pennsylvania.....	Jan. 5-12.....		1 death.
Memphis, Tennessee.....	Jan. 5-12.....	8 cases.	
Nashville, Tennessee.....	Jan. 5-12.....	5 cases.	
Wheeling, West Virginia.....	Jan. 5-12.....	1 case.	

Small-pox—Foreign.

Prague, Austria.....	Dec. 22-29.....	12 cases.	
Port Elgin and Cape Tarmen tine, New Brunswick, Canada.....	Dec. 28.....	40 cases.	
Leeds, England.....	Dec. 29-Jan. 5...	1 case.	
London, England.....	Dec. 22-29.....	1 case.	
Bombay, India.....	Dec. 4-18.....		3 deaths.
Calcutta, India.....	Dec. 1-15.....		81 deaths.
Carachi, India.....	Dec. 2-16.....	16 cases.	2 deaths.
Madras, India.....	Dec. 8-14.....		1 death.
Veracruz, Mexico.....	Dec. 29-Jan. 5...	4 cases.	2 deaths.
St. Petersburg, Russia.....	Dec. 15-22.....	5 cases.	1 death.

Yellow Fever.

Havana, Cuba.....	Dec. 29-Jan. 5...	5 deaths.
Matanzas, Cuba.....	Dec. 29-Jan. 5...	1 case.
Veracruz, Mexico.....	Dec. 29-Jan. 5...	1 case.

Cholera.

Bombay, India.....	Dec. 4-18.....	6 deaths.
Calcutta, India.....	Dec. 1-15.....	56 deaths.
Madras, India.....	Dec. 8-14.....	1 death.

Plague.

Hong Kong, China.....	Nov. 24-Dec. 1..	2 deaths.
Bombay, India.....	Dec. 4-18.....	178 deaths.
Calcutta, India.....	Dec. 1-15.....	39 deaths.
Constantinople, Turkey.....	Jan. 11.....	On Steamship Ber- rig from Poti.

Marine-Hospital Service:

Official List of the Changes of Station and Duties of Commissioned and Non-Commissioned Officers of the United States Marine Hospital Service for the Seven Days ended January 17, 1901:

RAIG, R. C., Acting Assistant Surgeon. Granted leave of absence for seven days.

LENNAN, A. H., Surgeon. Detailed to represent the service at the meeting of the Third Pan-American Medical Congress, to be held in Havana, Cuba, from February 4th to the 8th.

LAVINDER, C. H., Assistant Surgeon. To proceed to Vineyard Haven, Massachusetts, and assume temporary charge of the service during the absence of Surgeon F. W. Mead.

McMULLEN, JOHN, Assistant Surgeon. Granted leave of absence for twenty-one days from January 21st.

MEAD, F. W., Surgeon. Granted leave of absence for sixty days from January 21st.

NYDEGGER, J. A., Passed Assistant Surgeon. Granted leave of absence for thirty days.

SAWTELLE, H. W., Surgeon. Leave of absence for thirty days granted by Bureau letter of December 18, 1900, revoked.

THOMAS, A. R., Passed Assistant Surgeon. To proceed to Shields, England, for special temporary duty. Relieved from duty in Glasgow, Scotland, and assigned to duty in the office of the United States Consul-General in London, England.

Army Intelligence:

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from January 5 to January 19, 1901:

ARTHUR, WILLIAM H., Major and Surgeon, will report to the commanding general, Department of Northern Luzon, for duty.

BANISTER, WILLIAM B., Major and Surgeon, will report to the commanding general, Separate Brigade, Provost Guard, Manila, for duty as surgeon of the Twentieth Infantry.

BRADLEY, ALFRED E., Captain and Assistant Surgeon, is detailed to take charge of the office of the chief surgeon of the Department, in addition to his present duties, during the illness of the latter, and will make four round trips a week between Fort Snelling and St. Paul.

CHAMBERLAIN, WESTON P., First Lieutenant and Assistant Surgeon, is granted leave of absence for one month.

COMEGYS, EDWARD T., Major and Surgeon, is assigned to the command of the First Reserve Hospital, Manila, relieving **WILLIAM R. HALL,** Major and Surgeon, who will report to the commanding general, Department of Southern Luzon, for duty.

EDIE, GUY L., Major and Surgeon, will report to the commanding officer of the first available transport carrying sick to the United States, for duty thereon while en route to San Francisco, and will return to Manila.

MEACHAM, FRANKLIN A., Major and Surgeon, will report to the commanding general, Separate Brigade, Provost Guard, Manila, for duty as president of the Board of Health of Manila.

SIMPSON, MAXWELL S., Captain and Assistant Surgeon, Squadron Philippine Cavalry, having tendered his resignation, is honorably discharged from the service of the United States, to take effect January 31, 1901.

A board of medical officers to consist of **BENJAMIN F. POPE,** Lieutenant-Colonel and Deputy Surgeon-General; **FRANCIS J. PURSELL,** Acting Assistant Surgeon; **A. J. PEDLAR,** Acting Assistant Surgeon, is appointed to meet at the Presidio of San Francisco for the examination of candidates for the position of acting assistant surgeon.

Naval Intelligence:

Official List of Changes in the Medical Corps of the United States Navy for the two weeks ending January 19, 1901:

DENNIS, J. B., Assistant Surgeon. Ordered to delay reporting for duty at the Naval Academy.

LIPPITT, T. M., Assistant Surgeon. Detached from the Naval Hospital, Yokohama, Japan, and ordered to the Naval Hospital, Mare Island, California, via the *Solace*.

PRYOR, J. C., Assistant Surgeon. Ordered to duty at the Naval Hospital, New York.

WILLIAMS, R. B., Assistant Surgeon. Detached from the Navy Yard, New York, and ordered to the Navy Yard, Pensacola, Florida.

WRIGHT, B. L., Assistant Surgeon. Detached from the Naval Hospital, Yokohama, Japan, and ordered to the Naval Hospital, Mare Island, California, via the *Solace*.

A Book on Army and Navy Cooking.—We learn that **Anton F. Miller,** of the U. S. Army Hospital Corps, has compiled a *Manual for Hospital and Army Cooks,* which has been sent to the surgeon-general. Mr. Miller has had many years' experience as a cook and steward, and should know whereof he writes.

The Chicago Clinic has been purchased by Dr. George Thomas Palmer and will hereafter be edited by Dr. Marcus P. Hatfield. A special feature will be made of a series of papers on the relation of the law to physicians, by Hon. John Mayo Palmer.

Epidemic in New Jersey State Prison.—An epidemic of grippe has broken out in the New Jersey State Prison and 140 convicts, or about 15 per cent. of the entire prison population, are suffering from the malady. Most of the cases are slight.

Osteopaths to be Licensed in Wisconsin.—A bill has been introduced in the legislature of Wisconsin providing for a State board of osteopathy. This is a move on the part of the osteopaths to secure registration without having to go before the board of medical examiners.

Plague among British Troops is said by reports from Brussels to be raging in Cape Colony. It is stated that many deaths attributed to typhoid are really due to bubonic plague, but that the fact is concealed. It is doubtful how much credence can be attached to the report.

The Richmond Academy of Medicine and Surgery.—At the last regular meeting, on Tuesday evening, the 22d, the subject for discussion was a paper by Dr. J. Page Massie, entitled *Cæsarean Section*; the *Modern Antiseptic Method*.

The Chicago Eye, Ear, Nose and Throat College has moved into the four-story and basement building on the southeast corner of Franklin and Washington Streets. The building has been remodeled and equipped with the latest approved apparatus throughout for carrying on demonstrations. The new quarters will afford a largely increased space for the work of the college.

A Sturdy Veteran Practitioner.—Dr. John P. Wood of Coffeyville, Kan., who celebrated his ninety-ninth birthday anniversary on January 5th, has decided to take the lecture platform early this coming spring. He will lecture at first on *Longevity*. Dr. Wood is probably the oldest practising physician in the world. He is unusually hale and hearty, and is feeling better now than for many years.

The Boston Medical Society Building Dedicated.—More than 200 members of the medical profession in Boston assisted in the recent dedication of the new home of the Boston Medical Society. Guests were present from all parts of Massachusetts, among them being Dr. Francis W. Draper, president of the Massachusetts Medical Society.

Hospitals to be Exempted from Liability.—Nurses or attendants in hospitals sustained in whole or in part by charity, must alone be held responsible for their brutal or neglectful acts should a bill introduced by Senator Grady at Albany become a law. The bill exempts such hospitals from liability arising out of the neglect, want of skill, or malicious acts of their officers, agents, or employees, and provides that the individual offenders shall be liable in suits to recover damages.

A Congress of Medical Associations.—Headquarters have been established at the Aberdeen hotel, St. Paul, Minn., for the meeting to be held in that city during the first week of June, of the National Association of Military Surgeons, the State Medical Society, the American

Medical Association, the American Academy of Medicine, and the Society of Medical Colleges. Three hundred rooms have been engaged at the Aberdeen.

Richmond County Medical Society.—At the recent meeting of the Richmond County (N. Y.) Medical Society at Staten Island, the following officers were re-elected: President, Dr. Jefferson Scales; vice-president, Dr. C. Wilmot Townsend; secretary and treasurer, Dr. H. C. Johnstone; members of the board of censors, Dr. James J. O'Dea, Dr. Walker Washington and Dr. William Bryan; Dr. E. D. Wisely was elected delegate to the meeting of the State Medical Society.

The Middlesex South District Medical Society of Massachusetts celebrated its golden anniversary on January 17th, with a reception and banquet at the United States hotel, Boston. There were 175 guests present. A historical sketch of the organization was read and speeches were made by a number of prominent physicians. The newly elected officers are: President, Dr. C. H. Cook, of Natick; vice-president, Dr. E. G. Hoitt, of Marlboro; secretary, Dr. Albert August, of Cambridge; treasurer, Dr. Walter Ela, of Cambridge; librarian, Dr. E. Scott Dow, of Allston.

The Medical Association of the Greater City of New York met at the Academy of Medicine on Monday evening, January 14th. Dr. J. Blake White was elected chairman for the borough of Manhattan. Dr. Henry D. Nicoll presented a report as chairman of the memorial committee on the death of Dr. Horace T. Hanks, which was adopted. Papers were read on *The Operative Treatment of Umbilical Hernia in Adults*, by Dr. Joseph A. Blake, and on *Cocaine Anæsthesia in Eye Affections*, by Dr. Neil J. Hepburn.

A French Medical Association in Canada.—A movement has been started in Montreal by leading French-Canadian physicians for the organization of a French Medical Association embracing all the French physicians on this continent. It has been decided to hold a French medical congress in Montreal next summer, which is to form the basis of a permanent association. A French physician in Louisiana has written to the promoters that the physicians of that State are in full sympathy with the movement and will attend the congress. It is stated that there are over five hundred French physicians in the United States and Canada.

A Convention of Sanitarians.—The Pennsylvania Board of Health announces the eighth annual meeting of the Associated Health Authorities and Sanitarians of Pennsylvania at Harrisburg for February 6th and 7th. Governor Stone will preside. The annual address will be delivered by Dr. George G. Groff on *Sanitary Work in Puerto Rico since the American Occupation*. Water supply, city sanitary regulations and the means of preventing contagious diseases will be considered. The officials of the State Board of Health have made arrangements for reduced railway rates and hotel accommodations, particulars of which may be obtained by addressing Dr. W. B. Atkinson, 1400 Pine Street, Philadelphia.

The Erie County Medical Society.—At the eighth annual meeting of the Erie County Medical Society which was held in Buffalo on January 8th, the following officers were elected for the ensuing year: President, Dr. W. C. Phelps; vice-president, Dr. Walden M. Ward

North Collins; treasurer, Dr. Edward Clark; secretary, Dr. F. C. Gram; librarian, Dr. W. C. Callanan. Legislative committee, Dr. W. W. Potter, Dr. Ernest Wende, Dr. Edward Clark. Censors, Dr. J. B. Coakley, Dr. Henry R. Hopkins, Dr. Irving W. Potter, Dr. Francis E. Fronczak, Dr. Henry C. Lapp, Clarence.

Sisters' Hospital Election.—The annual meeting of the active staff of the Sisters' Hospital of Buffalo, N. Y., was held on January 9th, and the following officers elected: President, Dr. L. G. Hanley; vice-president, Dr. H. C. Buswell; secretary, Dr. Nelson W. Wilson; executive committee, Dr. James J. Mooney, Dr. Eugene A. Smith and Dr. Walter D. Green. The staff re-elected Dr. C. M. Daniels secretary by a unanimous vote, but Dr. Daniels declined the honor, and a new vote being ordered, Dr. Wilson was chosen unanimously.

Dr. Unna's Dermatological Clinics.—On the 1st of January Dr. Unna's clinic, which has heretofore been held at the dermatological laboratory at Heussweg 13, Erinsbüttel, Hamburg, was established on an independent footing with largely increased facilities. The following gentlemen will hold regular clinics in their several specialties: Dr. Abel, Dr. Cohn, Dr. Delbanco, Dr. Herz, Dr. Leistikow, Dr. Smilowski, Dr. Tropolowitz, and Dr. Unna. The lectures will be arranged in two courses of six weeks each, the first of which lasts from the beginning of February till the last of March, and the second of which begins at the end of September. Besides these lecture courses, students who are competent to conduct independent investigations may work the year round. All students have free admission to Dr. Unna's polyclinic and to his library.

Alumni Association of the Medico-Chirurgical Society.—At the eighteenth annual meeting of the Alumni Association of the Medico-Chirurgical College, Medical Department, at Philadelphia, the following officers were elected to serve for the ensuing year: Dr. John Welsh Crosky, president; Dr. Stillwell C. Burns, secretary; Dr. Samuel S. Gans, treasurer; executive committee, Dr. Easterly W. Ashton, Dr. A. E. Blackburn, Dr. Napoleon L. Boston, Dr. A. C. Buckley, Dr. Philip C. Cleaver, Dr. M. P. Dickeson, Dr. John H. Egan, Dr. Webster L. Fox, Dr. Charles H. Gubbins, Dr. Howard Kinne, Dr. Ernest Laplace, Dr. D. W. Levy, Dr. John A. McGlenn, Dr. John A. McKenna, Dr. A. C. Morgan, Dr. R. D. Newton, Dr. G. E. Pfahler, Dr. G. W. Pfromm, Dr. Alexander Romsay, Dr. J. B. Roxby, Dr. J. V. C. Roberts, Dr. H. J. Smith, Dr. J. V. Shoemaker and Dr. M. P. Warmuth.

Massachusetts Surgical and Gynæcological Society.—At the annual meeting in Boston the Massachusetts Surgical and Gynæcological Society elected the following officers: Dr. H. E. Spaulding, president; Dr. G. F. Martin and Dr. W. T. Hopkins, vice-presidents; Dr. T. M. Strong, general secretary; Dr. H. D. Boyd, assistant secretary; Dr. Grace E. Cross, treasurer; Dr. M. H. Houghton, auditor; Dr. George F. Adams, Dr. George H. Earle, Dr. Frank A. Gardiner, censors. Six doctors were admitted to membership. The following papers were read: Annual Summary of the Progress in Surgery and Gynæcology, by Dr. George E. May, of Newton Centre; Tic Douloureux Hysterectomy and Cure, by Dr. Lamson Allen, of Worcester, discussed by Dr. H. E. Spaulding and others; Sterility, by Dr. Charles T. Howard, of Worcester, discussed by Dr. N. W. Emerson, Dr.

G. R. Southwick, Dr. E. B. Cahill and others; Side Lights on Anæsthesia, by Dr. F. P. Batchelder, of Boston, discussed by Dr. J. B. Bell, Dr. Horace Packard, Dr. W. H. Stone and others; The Treatment of Epithelioma Other Than by the Knife, by Dr. J. L. Coffin, of Boston, discussed by Dr. Alonzo Boothby and Dr. A. H. Powers.

Diphtheria and Scarlet Fever.—An epidemic of diphtheria has become prevalent at Eastport, L. I., and alarm is manifested because of a likelihood of the disease becoming more widespread. Diphtheria has also put in its appearance in Central New York. Scarlet fever is alarmingly prevalent at Windsor, Mich.

Tuberculosis Should be Reported.—Representatives of the Philadelphia County Medical Society and the Society for the Prevention of Tuberculosis appeared before the bureau of health recently in Philadelphia to urge that the bureau compel the reporting by physicians of all cases of consumption. The board listened to the arguments and expressed its sympathy, but its chief, Colonel Good, pointed out that there was no legal power invested in him by which he could compel physicians to report such cases. Colonel Good also made clear the position of the bureau. While not favoring the placarding of houses wherein cases of consumption exist, nor the isolation of the patient, it does favor compulsory registration.

Grippe.—Surgeon-General Wyman, of the United States Marine-Hospital Service, at Washington, has taken cognizance of the prevailing grippe epidemic, an inquiry having been set on foot by him to ascertain its exact extent, severity, and peculiarities, in various parts of the United States. Surgeon-General Wyman has issued instructions to the officers of the service at the different seaports and cities to report fully all facts regarding the prevalence of the disease, the number of people affected, deaths resulting therefrom, and other information that will enable him to determine the cause of the epidemic and offer suggestions for guarding against it in the future. The various health board officials of different cities have urged the greatest precautions on the part of those persons susceptible to colds. In New York the number of deaths due to the grippe ranges into the hundreds.

Small-pox.—Small-pox is now uncommonly prevalent in the United States, the report of the Marine Hospital Service for January 1st showing its existence in forty-five of the fifty-one States and Territories, with a total of 9,229 cases, of which Ohio had 1,732; Tennessee, 1,405; Minnesota, 1,199; Texas, 674; North Carolina, 578; Nebraska, 467; Wisconsin, 412, etc. There were in Pennsylvania thirty cases, in New Jersey thirteen, in Delaware one, and in Maryland twenty-three. How quickly the disease may spread was shown in 1898. At the beginning of that year it was confined to four localities in three States (New York, Tennessee and Alabama); at the close of the year it was reported to be in 151 localities in twenty-four States. In New York, at present, small-pox is abating, although wholesale vaccination is still being practised.

The Health of Havana.—The official report of Major W. C. Gorgas, chief sanitary officer of Havana, for the month of December, shows that the death rate has sunk to 23.28 per thousand, the lowest death rate recorded in the history of the city. In December, 1897, the rate was

100.18 per thousand; in 1898, 96.27; in 1899, 27.10. There were 21 deaths from yellow fever out of a total of 485 deaths for the month. During the month, 119 new cases of yellow fever were reported. Examinations of premises to the number of 10,500 were made during the month.

The Death Rate of Santiago, as shown by the official report of Dr. Ira A. Shiner, United States Army, president of the board of health, was only 17.86 per thousand during December, as against the following rates in previous years: 1888, 30.66; 1889, 25.86; 1890, 25.33; 1891, 24; 1892, 23.73; 1893, 22.66; 1894, 27.73; 1895, 58.40; 1896, 73.33; 1897, 101.06; 1898, 78.93; 1899, 26.99. There has been no yellow fever reported during December for three years past.

Brooklyn's Death Rate.—The recently issued report of Dr. Sylvester J. Byrne, head of the bureau of records of the Brooklyn health department, shows that there have been more deaths than births recorded in the Brooklyn health office. Dr. Byrne's report shows that in 1900 the number of deaths reported in Brooklyn was 23,475; the number of births, 22,572. In 1899, according to the report, 21,683 persons died in Brooklyn, while only 21,203 were born in the borough during the same year. The figures in 1898 were: Deaths, 21,856, and births, 21,395. It would appear from these figures that more Brooklynites are going out of the world than are coming into it, but Dr. Byrne declared that such was not the case. The births, he said, quite invariably exceeded the deaths in number, and the failure of the department records to present this fact was due to the negligence of physicians in reporting the births.

Diphtheria Antitoxine to be Furnished Free.—The recent action of the common council of Sioux City, Ia., places antitoxine upon the same standing in that city as vaccine virus. On the advice of the city health officer, the council approved a measure which makes imperative the inoculation with antitoxine of all members of families in which there is a case of diphtheria. This is believed to be the most radical step so far in this country in the use of antitoxine, and it has met with the opposition of many physicians. The latter declare that inoculation with antitoxine produces such different results in different individuals that it is impossible to foresee the consequences, which are often serious. Some physicians who are opposed to the measure assert that exposure to diphtheria in its early stages rarely causes contagion, but that the use of the serum much more frequently produces ill effects, and in many cases light forms of the disease itself.

The Health Department Appeals to Comptroller for Necessary Funds.—Assistant Health Commissioner Francis, of St. Louis, recently notified Comptroller Sturgeon that unless more money was provided for this purpose during the month of January the city would be left without the material for checking the spread of contagious diseases. Mr. Francis has countermanded an order for a large quantity of formaldehyde, and the department will have to purchase a much smaller quantity, paying a higher price. In his letter Mr. Francis states that the appropriation of \$13,000 for disinfectants is nearly exhausted, and that it cannot be made to last longer than February 1st. The appropriation of the previous year was \$14,000, which sum sufficed, but Mr. Francis explains that the number of cases of diphtheria and typhoid and the number of houses fumigated to the

present time have been one third greater than in the same period of the previous fiscal year. In another department, the coroner's, the work of the postmortem examinations is being carried on absolutely without funds.

Sues the Doctors who Declared him Insane.—Dr. Henry Flood and Dr. E. A. Reilly, of Elmira, N. Y., are defendants in an action for \$50,000 damages brought by James Coyle, of Brooklyn, who alleges conspiracy in having been pronounced insane by them. Coyle had business and domestic troubles which figured in the courts. Mrs. Coyle made application to County Judge Pratt for the appointment of a commission to examine her husband as to his sanity. Judge Pratt appointed the doctors, who, after an examination, reported that they had found the patient to be insane. A commitment was made out to the Binghamton State Hospital, but Coyle could not be found. He was next heard from in Brooklyn. Coyle returned to Elmira, and new proceedings were brought and a second commission was appointed to examine him. This time Coyle objected to the proceedings and legally opposed them. He was taken to New York, where he was examined by Dr. Carlos McDonald and pronounced sane. The proceedings to have him committed were dismissed and he returned to Brooklyn and secured a position on a railroad. He alleges that because of the local decision declaring him to be insane, he has lost his position.

Foreign University News.—Dr. A. Schüle, *privat-docent* at Freiburg, has been made professor extraordinary.—Dr. Wollenberg, chief physician to the hospital for the insane at Hamburg, has been appointed professor of mental diseases at the University of Halle to succeed Professor Siemerling, who goes to Kiel.—Professor Ewald has succeeded Dr. Goltz as director of the physiological institute at Strassburg.—Dr. M. C. Simon has been appointed professor of surgical pathology and operative medicine at the University of Rheims.

Foreign News Notes.—An association for the higher education of practising physicians has been formed in Berlin. The association will arrange for a series of lectures by eminent specialists which will be open to any physician practising in Berlin or the vicinity on the payment of a merely nominal fee (2 marks) for the clinical expenses incurred. It is expected that a large number of lecturers will be engaged in addition to the following, who have already agreed to lecture upon the respective subjects named: Professor Eulenberg, on nervous diseases; Dr. Finkelstein, on pædiatrics; Dr. Jansen, on otology; Dr. Max Joseph, on dermatology; Dr. Koblank, on obstetrics; Dr. Robert Kutner, on genito-urinary diseases; Dr. Meyer, on diseases of the throat and nose; Professor Reuvers, on internal medicine; Professor Rotter, on surgery; Professor Silex, on ophthalmology; Dr. von Wasielewski, on certain phases of hygiene and bacteriology. The courses are to begin next April and they will be divided into winter and summer sessions. Professor E. von Bergmann is president of the association, and Dr. Robert Kutner is the secretary.

Foreign Obituary Notes.—Dr. Pierre Karl Edouard Potain, professor of clinical medicine in the medical faculty of the University of Paris, died on January 5th, at the age of seventy-five years. Professor Potain was the author of several important articles in the *Dictionnaire encyclopédique des sciences médicales*, and was an occasional contributor to current medical literature. He remained in active practice up to the day previous to

his death.—Dr. James Morris, Fellow of the University of London, and author of *Germinal Matter and the Contact Theory*, and of *Morbid Conditions Bordering on Disease*, died in London on December 23d, at the age of sixty-five years.—Dr. John B. Potter, obstetric physician to the Westminster Hospital, London, and a prominent member of the Obstetrical Society of London, died on December 30th, at the age of sixty-one years.—Dr. L. Ollier, professor of clinical surgery at Lyons, died suddenly on November 25th. He was well known to the profession outside as well as in France through his original work and his valuable contributions to medical literature. His most important works are a treatise on the regeneration of bone and the artificial production of bony tissue and a work on the conservative surgery of the bony structure. A committee has been formed in France for the purpose of erecting a monument to his memory.

Lady Curzon's First Public Speech.—According to the *Indian Medical Record* for December 19, 1900, her excellency Lady Curzon recently made her first public speech to a large assembly at Bangalore on the occasion of opening a new hospital for women and children in that town. In a clear, self-possessed voice, her excellency said: "It gives me great pleasure to come here to-day to open this hospital; and it is a matter of great gratification to me that it is to be called by my name. It is not possible for a viceroy's wife to take part in any of the public duties and responsibilities of her husband; but one sphere of work it has always been her happy privilege to take part in; and I feel that I am only carrying on the tradition, bequeathed to me by the wives of successive viceroys, when I take part in so interesting a function, and express my deep concern and tender sympathy with all efforts to relieve the suffering of my sex and of the children in India. In this cause there is no such thing as distinction of race or creed, since suffering or distress is the bond that makes all humanity one. It was therefore a delight to me to open this hospital, which has been so very generously subscribed to by the gentlemen to whom Colonel Dobson has referred. I congratulate the committee on the admirable plan of the hospital, and the outlying wards for caste, non-caste, and European cases, and trust that each will prove an infinite blessing to the sufferers for whom they are set apart. I am very proud to receive such a beautiful key and casket, and thank the committee very warmly."

A Tuberculosis Hospital for Connecticut.—A bill has been introduced in the Connecticut legislature for the establishment and maintenance of a tuberculosis hospital at New Haven, and an appropriation of \$100,000 is asked for that purpose.

The Brooklyn Eye and Ear Hospital.—At the annual meeting of the board of directors of the Brooklyn Eye and Ear Hospital, the following officers were elected for the ensuing year: President, Carll H. De Silver; vice-president, Thomas E. Stillman; treasurer, Henry D. Atwater; secretary, F. H. Colton, M. D.

Mount Zion Hospital, San Francisco.—A grand ball is to be given on February 2d at the Palace hotel, San Francisco, to raise funds for the benefit of the Mount Zion Hospital. The directors of the hospital desire to raise enough money to build an extra wing to the hospital. The present accommodations of the hospital are too small and if this extension were added it would give room for the care of paying patients which would defray

the expenses of the hospital. Mount Zion is free to the poor of all people, irrespective of creed or nationality.

Changes at the City and County Hospital, San Francisco.—It is announced that sweeping changes are in contemplation in connection with this institution. The funds of the board are so low that a saving of some \$300 or \$400 must be made somewhere, and the hospital committee has decided that at least six or eight employees—names have not yet been decided upon—must lose their positions. The committee believes that the efficiency of the service will not be impaired by curtailing the staff, as under reorganization the work will be so apportioned as to leave no portion of the hospital neglected. At the beginning of the new fiscal year in July next it is said that still another organization will take place, as the board is determined to reduce the expense of management to the lowest possible point.

Hospital Staff Changes.—Governor Odell has appointed Mr. G. L. Thompson to act as a member of the board of managers of the Long Island Hospital in place of Mrs. Mary E. Jones, of Cold Spring Harbor, who has resigned.—Dr. William J. Chandler, of South Orange, N. J., has been appointed on the staff of the Orange Memorial Hospital to fill the vacancy caused by the death of Dr. William Pierson, and Dr. Harry E. Matthews and Dr. Mefford Runyon have been appointed to the general staff. Dr. Frank H. Glazebrook has been appointed house physician.—Dr. F. S. Ward, who has for the past two years been in charge of the pathological work of the Taunton, Mass., State hospital, has resigned his position with that institution and has opened an office for private practice in Springfield, Mass.—Dr. Hiram N. Vineberg has been appointed adjunct attending gynecologist to Mount Sinai Hospital, New York City.

Dr. J. W. Moore Reinstated at Bellevue.—Dr. J. W. Moore, who was suspended by John W. Keller, Commissioner of Charities, has resumed his duties as a member of the medical house staff of Bellevue Hospital, as reported in our last issue. At the time Dr. Moore was suspended, Commissioner Keller said that after reading the testimony given by Dr. Moore at the Hilliard inquest he thought it showed that Dr. Moore had been negligent, and he had therefore suspended him. A transcript of the evidence was sent to the Committee of Five of the medical board of the hospital. Soon after this committee was appointed, it decided that the work of caring for the patients in the alcoholic and the insane wards was too much for one interne, and it assigned one interne to have charge of the alcoholic ward and another to attend to similar duties in the insane ward. Dr. Moore had had charge of both wards. This action was considered favorable to Dr. Moore. One result of the conferences between Commissioner Keller and the committee of the medical board has been the formulation of regulations fixing the responsibility for the care of patients, and the defining of the relations and duties of physicians and nurses, so as to form a chain of responsibility, which Commissioner Keller hopes will make abuses and ill-treatment of patients practically impossible in future.

Hospital Buildings and Endowments.—William T. Wardwell, president of the Red Cross Hospital, in West Eighty-second Street, New York, has given \$40,000 to the institution to aid the erection of a new hospital.—A maternity department has been added to the Children's Hospital of Germantown, Pa.—The will of

Henry T. Dortie, a wealthy New York business man, contains the following bequests: New York Eye and Ear Infirmary, \$3,000; New York Society for the Relief of the Ruptured and Crippled, \$3,000; Manhattan Eye and Ear Hospital, \$3,000; St. Mary's Free Hospital for Children, \$3,000; New York Skin and Cancer Hospital, \$3,000.—Owing to the overcrowded condition of the State Hospital for the Insane at Augusta, Maine, the erection of a new hospital was begun six years ago at Bangor. Thus far, \$440,000 has been expended, of which \$35,000 was advanced by the governor from his private means, and the new hospital is still incomplete. The legislature is to be asked for a further appropriation of \$200,000.—The contract for the new almshouse hospital building at Buffalo, N. Y., has been let for the sum of \$49,900.—A charity hospital is to be erected at Eureka Springs, Arkansas, at a cost of \$5,000 by Mrs. R. C. Kerens, of St. Louis.—Secretary Gage has requested from Congress an appropriation of \$20,000 for the improvement of the buildings of the Marine-Hospital Service at Chicago.—A bequest of \$11,000 has been made to the Delaware Hospital of Philadelphia by the will of Dr. William Wood Lesley, of that city.—A new hospital is to be built at Albuquerque, N. M., the cost of which will be \$25,000. It is to be in charge of the sisters of charity.—Miss Mira Hershey, of Los Angeles, Cal., purposes to found a free hospital at Muscatine, Iowa, at a cost of \$300,000.—The question of the erection of a new \$40,000 hospital, instead of adding a wing to the old structure, is being considered by the directors of the Union Hospital of Terre Haute, Ind.—The twelfth annual report of the Babies' Hospital of the City of New York, makes a strong appeal for aid in increasing the building and endowment fund to \$200,000. It is desired to erect a new hospital, as the old buildings cannot accommodate all the patients seeking admission.

Births, Marriages, and Deaths.

Married.

BRACKETT—PEDRICK.—In Marblehead, Massachusetts, on Thursday, January 17th, Dr. Elliot Gray Brackett, of Boston, and Miss Katharine Frances Pedrick.

DUNCAN—OGBURN.—In Mount Holly, Pennsylvania, on Thursday, January 3d, Dr. Joseph P. Duncan, of Princeton, N. J., and Miss Mabel Ogburn.

LEITER—CUSHWA.—In Baltimore, on Wednesday, January 16th, Dr. James W. Leiter, of Washington, and Miss Jane Frances de Chantal Cushwa.

LEWIS—MOSELEY.—In Manila, Philippine Islands, on Wednesday, December 12th, Dr. William F. Lewis, United States Army, and Miss Lillian Moseley.

MCCALL—BASKETT.—In Mexico, Missouri, on Thursday, January 10th, Dr. G. D. McCall, of Fulton, Missouri, and Miss Annie Baskett.

SEVERSON—MEAD.—In Chicago, on Wednesday, January 16th, Dr. Frank Millard Severson, of Seneca Falls, N. Y., and Miss Anna Evelyn Mead.

TINCHER—CARTER.—In Mexico, Missouri, on Thursday, January 10th, Dr. E. H. Tinchler, of Fulton, Missouri, and Miss Maude Carter.

Died.

ADEE.—In Washington, on Thursday, January 10th, Dr. David Graham Adee.

BOOTH.—In Shreveport, Louisiana, on Thursday, December 27, 1900, Dr. A. R. Booth, United States Marine-Hospital Service, in the sixtieth year of his age.

BROWN.—In Washington, on Wednesday, January 16th, Dr. Benjamin Brown, of Chicago, aged sixty-six years.

COLE.—In San Francisco, on Tuesday, January 15th, Dr. Beverley Cole, aged seventy years.

CONNALLY.—In Abilene, Texas, on Sunday, January 13th,

Dr. William Prescott Connally, of Atlanta, in the twenty-seventh year of his age.

GASTON.—In Indianapolis, on Thursday, January 10th, Dr. John M. Gaston, in the eighty-second year of his age.

GRAHAM.—In Pittsburgh, on Sunday, January 20th, Dr. Robert Graham, of Lexington, Kentucky, aged seventy-nine years.

HALBURT.—In Canastota, New York, on Friday, January 11th, Dr. Horace Halburt.

IRELAND.—In Baltimore, on Monday, January 14th, Dr. David Caldwell Ireland, in the fifty-eighth year of his age.

McKELVEY.—In Bloomsburg, Pennsylvania, on Tuesday, January 15th, Dr. James Boyd McKelvey, aged seventy-six years.

SMITH.—In Montreal, on Wednesday, January 2d, Mrs. A. L. Smith, wife of Dr. A. Laphorn Smith.

VON CLOSSMAN.—In St. Louis, on Friday, January 11th, Mrs. Martha H. von Clossman, wife of Dr. A. von Clossman, United States Army.

Obituaries.

PROFESSOR POTAIN,

PARIS, FRANCE.

ON the night of the 4th of January Pierre Karl Edouard Potain, honorary professor of the Faculty of Medicine of Paris, member of the Institute of France, and commander of the Legion of Honor, died suddenly at his home in Paris.

Born in Paris on the 10th of July, 1825, he began his medical studies at the Paris school of medicine in 1843, became interne in 1848, and graduated in 1853, passing his thesis for the Doctorate on the subject *Les souffles vasculaires qui suivent les hémorrhagies*. This remarkable work showed what might be expected of Potain, who devoted almost his whole life to the study of diseases of the heart. In 1859 he became adjunct professor, and in 1876 professor of clinical medicine in the faculty of medicine of the University of Paris, and taught for ten years at the Necker Hospital, and from 1886 to 1900 at the Charité Hospital.

His contributions to medical literature on nearly all subjects of internal medicine, but more particularly on diseases of the heart and blood-vessels, are numerous. His articles in the *Dictionnaire encyclopédique des sciences médicales* are a marvel of erudition, and his book *Leçons cliniques de la Charité*, published in collaboration with François Frank and his pupils Vaquez, Teissier, and Suchard, will remain a standard work on diseases of the heart for many years to come. He had probably the largest consultation practice of any one in Paris. His kindness to the pupils, his gentleness to his poor patients, his justice in the examination of students, which was always tempered with kindness, made him one of the most beloved of all the teachers in the faculty of medicine. He was a physician for over fifty years and a teacher for forty years. Throughout his long career Professor Potain was honored by his colleagues, beloved by his countless patients among rich and poor, and worshipped by his pupils. He had no enemies, and those who knew him could understand why he had none. He deserved the admiration and veneration which were recently manifested anew when he resigned his position a clinical teacher last year and was made honorary professor, and his pupils from all over the world united to present him with a gold medal as a token of their esteem.

In the death of Professor Potain France has lost one of her noblest sons, the medical profession one of its most illustrious members, the world a good and noble man.—S. A. Knopf, M. D.

Pith of Current Literature.

Journal of the American Medical Association,
January 19, 1901.

A Clinical Study of One Hundred and Fifty Cases of Hyperphoria. By Dr. Wendell Reber.

Ocular Complications of Injuries to the Head. By Dr. John T. Carpenter.—The author discusses these complications, and gives illustrative cases, one of which is particularly interesting because of the irritative symptoms, namely, spasm of convergence and photophobia, due to traumatic meningitis of the anterior portion of the skull, followed by paresis of the left external rectus and levator palpebræ superioris, with left optic neuritis. The association of paralysis of a branch of the third, with paralysis of the sixth nerve, and optic neuritis on the same side, make it possible to locate the intracranial lesion at or near the sphenoidal fissure.

The Silver-injection Treatment of Pulmonary Consumption. By Dr. Thomas J. Mays.—The author believes that any therapeutic agent which affects this disease favorably and permanently appeals, either directly or indirectly, to the pulmonary organs through the nervous system. After making an effort to reach the lung condition of this disease through the pneumogastric nerves, by massaging, kneading, and compressing them, he finally concluded that the subcutaneous introduction of some well-known conservative irritant, like nitrate of silver, immediately over the course of the nerves in the neck, would furnish the stimulus necessary to modify the morbid condition of the lungs. The author's practice is to inject five minims of a two-and-five-tenths-per-cent. solution of this agent preceded by a cocaine solution of the same strength and dose. A week or ten days should elapse before the injections are repeated, and there should be the same interval between all successive injections. The author has used these injections in one hundred and fifty cases. The best results are obtained in incipient cases, both in regard to the symptoms and to the physical signs. In most of the advanced cases they have a beneficial and, in some instances, an exceptional influence on the symptoms and physical signs. In the great majority of the far-advanced cases they ameliorate cough, expectoration, and other symptoms temporarily, while in some instances their effects are apparently lasting.

Tuberculosis of the Lungs Treated by Compression with Nitrogen after the Method of Murphy. With Further Remarks on the Rationale of the Procedure and a Record of Experiments on Dogs. By Dr. A. F. Lemke.—Tuberculous lungs after compression show much fibrosis in and about the foci of the disease; hence extension from these foci is less likely to occur. As tuberculous lesions always heal by cicatrization it is rational in attacking them to further this natural tendency. Good effects of compression, locally, are brought about by the limitation of the areas of disease already existing by favoring fibrosis in and about these areas; by occluding the avenues of dissemination of the virus, and by compressing cavities to enable them, mechanically, to heal. Other effects of compression are due to rest to the organ as a whole; the emptying of secretions; the prevention or diminution of absorption of toxic bodies; the prevention of secondary infections, and the diminished tendency to hæmorrhage. The actual risk of the operation is very slight. Uses of intrapleural injections of nitrogen: (1) curative in pulmonary tuberculosis; (2) palliative—to prolong life for weeks or months, though the disease be too extensive to

make recovery probable; to diminish fever and expectoration; (3) to check pulmonary hæmorrhage; (4) to compress cavities, tuberculous and other, and to establish mechanical conditions that will permit their healing; (5) to compress the lung just prior to surgical operations in which the pleural cavity is to be freely opened, and to determine the presence or absence of pleural adhesions before opening the pleural cavity to drain abscesses or bronchiectatic cavities, cysts, etc.

Angina Epiglottidea Anterior. Report of Three Cases. By Dr. Clement F. Theisen.—This is very often primary and is an acute infectious process. The term "acute infectious epiglottiditis" is suggested for this condition as being more scientific, and more fully explaining its probable nature. The inflammation and œdema involve only the anterior surface of the epiglottis.

Athresia Infantum—Marasmus, or Wasting Disease—Atrophy—Mal-assimilation of Food: Its Cause and Treatment—Proper Infant Feeding. By Dr. Louis Fischer.—No matter how beneficial boiling, or sterilization, or pasteurization may be, they cannot transform cow's milk into woman's milk, and it is a mistake to believe that the former, by mere sterilization, is a full substitute for the latter.

Light and Seating in the School. By Dr. C. Zimmermann.—The window surface should be to the floor surface as one is to five, and the width of the schoolroom must not exceed twice the distance between the desk and the upper window-sill. As to position, it is well to recollect that the best constructed seats and desks cannot prevent children assuming faulty positions, if not carefully watched.

Some Remarks on the Plantar Reflex, with Special Reference to the Babinski Phenomenon. By Dr. J. T. Eskridge.

Costa Rica: Its Physicians and Medical Institutions. By Dr. N. Senn.

Medical Record, January 19, 1901.

The Mosquito Theory of the Transmission of Yellow Fever, with its New Developments. By Dr. Charles Finlay.—When the *Culex mosquito, fasciatus*, is confined in an atmosphere artificially rarefied to correspond to altitudes of from four thousand to six thousand feet, it is unable to fly, at least for a while, or to sting. It seems unlikely, considering the smallness of this mosquito's wings, that it will, of its own accord, fly to any considerable height or distance, especially when weighted by the blood which it has absorbed. These peculiarities, according to the author, agree with what is known about the propagation of yellow fever, its tendency to invade the lower stories of buildings in preference to the upper ones, and its non-transmissibility in places like the City of Mexico, Puebla, Petropolis, situated at considerable altitudes above the sea level. The army yellow-fever board has placed beyond a doubt the fact that the *Culex mosquito, fasciatus*, does transmit the yellow fever from a patient to non-immune persons perfectly isolated from other sources of infection, and it has undertaken to demonstrate experimentally the fact that other sources to which the yellow-fever infection has been hitherto attributed are absolutely incapable of determining an attack of the disease.

Notes on Ovarian Grafting. By Dr. Robert T. Morris.—The consensus of opinion seems to be now that a properly transplanted ovary may continue to perform its full normal function, and that we may not only expect to prevent the symptoms of the menopause after a

patient's ovaries have been removed, but we may reasonably expect a pregnancy in a certain percentage of cases. The author believes that the reported cases of pregnancy after double ovariectomy, are in reality cases of pregnancy after accidental ovarian grafting. The special dangers to be expected from ovarian grafting would seem to be no more than the dangers from simple uncomplicated laparotomy.

Case of Thrombophlebitis of the Left Sigmoid Sinus Masking a Latent Brain Abscess in the Temporo-sphenoidal Lobe, both Arising from Chronic Otitis Media. By Dr. Carl Koller.—For the diagnosis of cerebral abscess in this case one had to depend more on the general symptoms present in the initial stage of the abscess than on any focal symptoms. An abscess in the latent stage can hardly ever be diagnosed, especially when masked by sinus phlebitis.

Subarachnoid Cocainization in Obstetrics and Gynecology: A Report of Twenty-one Cases. By Dr. N. J. Hawley and Dr. F. J. Taussig.—Fourteen of these cases were obstetrical and seven were gynecological. Concerning the technique of operation, the important points are: 1. Surgical cleanliness in all things and a fresh, aseptic solution of cocaine, full strength. The method of sterilization used at the present time is to raise the temperature of the solution (in small bottles) to 80° C. for one hour on two successive days. 2. The needle need not be longer than seven centimetres and should be kept sharpened. 3. A nurse should stand at the patient's head when the puncture is made, to keep the back arched forward. 4. During an operation the patient's ears should be kept closed with cotton and the eyes covered with a towel or cloth. As the result of experience, the author supports the view that spinal anaesthesia is not very dangerous except, perhaps, to the child *in utero*. When it produces disagreeable symptoms they are usually transient. In the labor cases it usually retarded progress. In instrumental deliveries, when urgency is required and the patient is not of a very nervous temperament, the spinal narcosis seems to meet every indication. In minor gynecological work it seems to have its greatest field of usefulness.

Important Points in the Management and Treatment of Consumption. By Dr. Charles R. Upson.—While some writers advise against the use of intrapulmonary medication, the author takes exception to such views, and he asserts that properly selected remedies thus applied may have great value. He has found a mixture of eucalyptol, pine-needle oil, menthol, and formic aldehyde to be most beneficial. He urges upon physicians the importance of the strictest attention to the hygienic environment of the consumptive patient. "The more rigidly we follow the methods adopted in lung sanatoria in the management of these patients, the greater will be our success—the constant supervision and control of the patient being the most important factor in the cure of the disease."

Philadelphia Medical Journal, January 19, 1901.

On Perforation and Perforative Peritonitis in Typhoid Fever. By Dr. William Osler.—There are many lessons to be learned about typhoid fever, but one that the author particularly wishes to enforce is the necessity of watching carefully in the severe cases for the very first features of perforation, in order that the patient may be given the benefit of operation at the earliest possible moment. In general hospitals it may be feasible in the future to save one half, at least, of the

perforation cases. In the severer cases the condition of the bowel is hopeless. In another group, the patients recover from the operation, but die of the effects of the disease itself. One of the most gratifying circumstances connected with the disease is the demonstration by the surgeons that there is a third group in which complete and perfect recovery may follow. In the limited number of operations performed thus far the percentage of recovery has been 37.5.

Hæmoglobinuria Complicating Typhoid Fever. By Dr. John H. Musser, and Dr. Aloysius O. J. Kelly.—Aside from the rarity of the complication, this case is interesting because of the absence of malaria as an ætiologic factor, the association of marked hæmoglobinæmia, the persistence of the hæmoglobinuria for at least seven days, and the ultimate recovery of the patient.

Two Cases of Localized Neuritis Occurring as a Complication of Typhoid Fever. By Dr. H. J. White.—This is one of the rarer of the many and widely distributed complications of typhoid fever. Multiple neuritis is much more common and its ætiology is fairly well established, the most generally accepted theory being, that the toxine produced by the typhoid bacillus acts directly on the nerve fibres, causing a mild perineuritis. The singling out of one nerve, or set of nerves, however, must be due to some special individual susceptibility to the effects of the toxine. The author's first case is one of double ulnar neuritis, which is more marked on the right side. The second case is one of a still more uncommon condition called *the tender toes of typhoid fever*. The question of a local inflammatory condition might arise, but the absence of redness, swelling, and heat, as well as the absence of leucocytosis, would entirely exclude that condition.

The Phenomena of Atropine Poisoning Following the Cessation of the Respiratory Movements. By Dr. Edward T. Reichert.—The results of the author's experiments on dogs with enormous doses of atropine have a very important bearing upon the treatment of poisoning in man. They show clearly that death is due to a paralysis of the respiratory centre, that the centre has great recuperative power, and that if artificial respiration is properly practised the respiratory centre recovers its activity, which is accompanied by general and marked improvement of other depressed states. In man, it seems that atropine poisoning should be readily treated if artificial respiration is persistently and intelligently practised, as by Laborde's method, and accompanied by such other treatment as indications suggest.

Report of a Case of Cholelithiasis with Formation and Rupture of an Abscess of the Abdominal Wall. By Dr. John H. Gibbon.—An interesting question suggested by the author's case is that of diagnosis, and he refers to the fact that there is sometimes difficulty in making a diagnosis between inflammatory conditions of the gall bladder and the appendix, and also to the fact that a number of excellent surgeons have reported cases where they operated, expecting to find one of these conditions and, to their surprise, have found the other. In this case the abnormal situation of the gall bladder—in the right iliac fossa—is also of interest.

A Case of Mirror-writing and of Diffuse Hypertrophy of both Breasts in an Epileptic Negress. By Dr. W. G. List.

Medical News, January 19, 1901.

Conclusions Formed after Six Years' Experience with the Antitoxine Treatment of Diphtheria. By Dr.

Henry F. Koester.—Antitoxine, to obtain its best effects, must be used fearlessly and in quantity sufficient to be effective, which is never less than two thousand units, in very mild cases. In severe cases at least three thousand units must be used, and this dose repeated in from twelve to twenty-four hours. Antitoxine in itself, contrary to the expressed belief of some observers, never does any harm. The author concludes: (1) that antitoxine is a positive cure for diphtheria, when employed in sufficient quantity and sufficiently early in the disease; (2) that even when employed too late in the disease to produce its specific action, it cannot under any circumstances be productive of harm; (3) that when used before the invasion of diphtheria, antitoxine possesses a positive immunizing power which lasts for about thirty days.

Problems in the Ætiology, Diagnosis and Treatment of Tuberculous Disease of the Upper Air-passages. By Dr. Jonathan Wright.—The author protests against the tendency to consider the tubercle bacillus as the *sole* agent in the production of tuberculosis. He also denies that the tubercle bacilli are ever the cause of large tonsils and adenoids, and he is disposed to doubt that this overgrowth of tissue is the *chief* pathway by which the tubercle bacillus enters the organism. He believes that the bacillus usually enters the tissues of man before it reaches the stomach by the œsophagus, or the lungs by the trachea. As to diagnosis, it is important, in these cases of laryngeal disease, both in the incipient stage and in the ulcerative stage, where there is danger of confounding it with syphilis, that the sputum analysis should not be neglected. If the bacillus is not found, iodide of potassium and mercury should be given until the case is cured or the diagnosis is clear. Treatment of this disease is a most vivid reminder of the impotency of man in the face of the destructive forces of Nature. Climatic change is the most effective agent. A certain very small number recover under surgical treatment. Lactic acid, and probably some other drugs, will stimulate torpid granulations to a more florid and healthy appearance, and it will frequently cause a marked diminution in the amount of secretion. The local application of iodoform, and especially of orthoform, is of use. The employment of opiates is often justifiable and indicated. Detergent sprays may be used to wash away the secretions.

Notes on the Interesting Cases of a Month's Dispensary Practice. By Dr. William L. Stowell.—A case of *universal eczema* is reported, in which the treatment consisted of solution aluminum acetate externally, with rhubarb internally. The tumefaction of the lips, eyes, and ears was prominent. The rapidity of extension and the fine, bran-like scales tended to strengthen the diagnosis. The patient was entirely cured in six weeks. The author also presents a case of typhoid fever. He says: "Nursing is more important than drugging." He contends that, as at present 27,000 patients (a standing army) are lost each year, exact rules should be laid down as to prophylaxis.

A Case of Adiposis Dolorosa. By Dr. Ellice M. Alger.—This disease always occurs in women, generally past middle life, and almost invariably has been associated with some neurotic or alcoholic taint. In the cases that have gone to autopsy, the thyreoid has been found to have undergone calcareous degeneration. The author's case was typical; the patient was put on gradually increasing doses of thyreoid extract, reaching as much as thirty grains a day. Some improvement followed. Under thyreoid medication the skin became notably less soft, and showed a brownish pigmentation.

Ligation of the Internal Jugular Vein Followed by Thrombosis of the Lateral and Sigmoid Sinuses. By Dr. Charles G. Levison.—The indications laid down by Rohrbach for ligation of the internal jugular are: (1) Hæmorrhage due to a laceration or erosion—here the lateral ligature or suture has its place; (2) tumors involving the brain; (3) periadenitis due to tuberculous lymphomata closely adherent and inseparable from the vein; (4) aneurysmal varices; (5) pyæmic otitis, complicated by thrombosis of the lateral sinus.

In the author's case, upon autopsy, infection was practically excluded, for the thrombus was in full process of organization.

Boston Medical and Surgical Journal, January 17, 1901.

Note on the Treatment of Epidermoid Cancer by the Röntgen Rays. By Dr. Francis H. Williams.—The author's experience at the Boston City Hospital would seem to indicate that we have, either in the x-rays themselves, or in some other form of radiation from an excited Crookes's tube, a valuable therapeutic agent in epithelioma, and that the beneficent action of the x-rays can be brought about without causing a burn. The earlier this treatment is undertaken the better. It is not improbable that we shall find its curative action limited to superficial growths, though as a means of relieving the painful features of the disease in other forms it may be of use.

Lancet, January 12, 1901.

Enlargement of the Prostate. By Dr. P. J. Freyer.—The overgrowth of the prostate gland may be uniform in character, the hypertrophy extending equally to all parts of the gland, which thus preserves its symmetry. This form of enlargement is least liable to be attended by symptoms. Or the enlargement may be limited to any one of the three lobes of the gland. It is the enlargement of the middle lobe that gives rise to the most urgent symptoms. This lobe has a tendency to grow upward and inward into the bladder, forming a pyramidal tumor which presses against and occludes the urethral orifice. The average weight of the normal prostate being six drachms, one weighing seven drachms is regarded as hypertrophied. As the prostate enlarges, the urethral orifice is carried up with it; a post-prostatic pouch is thus formed in the bladder, which is never emptied of urine during the acts of micturition. This "residual" urine gradually increases in quantity as the hypertrophy progresses and the muscular power of the bladder diminishes. In course of time changes occur in the ureters and kidneys from the backward pressure due to the obstruction of the urinary flow. Hæmorrhoids and prolapsus ani also occur frequently in connection with this disorder from straining at micturition.

The author reviews the various theories as to the causation of prostatic enlargement (Velpeau's and Guyon's), and rather inclines to the view that it is analogous to fibroid disease of the uterus. None of the symptoms are referable to the prostate itself. They are: (1) increased frequency of micturition; (2) difficulty in starting the stream; (3) diminution in the strength of the urinary flow; (4) straining to help the flow, but which has little or no effect in strengthening the stream; on the contrary, the straining may arrest the flow completely; (5) incomplete stoppage as indicated by dribbling at the end of micturition; and (6) intermittency of the flow due to the ball-valve action of the middle lobe. As the disease progresses, pain and hæmaturia supervene.

The author describes the method of passing a ca-

theter to draw off the residual urine, and the kind of catheter to be used. Little information with reference to the condition of the middle lobe can be gained by rectal examination. There may be great outgrowth of this lobe into the cavity of the bladder when no enlargement of the gland is to be recognized by rectal examination. Some information can be gained by the use of a short-beaked sound, but examination of the bladder by the cystoscope will, in a large proportion of cases, give a still more correct estimate of the size and shape of the middle lobe and as to whether or not it is capable of being removed by operation. (*To be continued.*)

Pneumococcic Arthritis. By Dr. E. J. Cave.—The author's article is based upon a tabulation of thirty-one cases of arthritis associated with the presence of the pneumococcus in the affected joint, which he has collected from the literature of the subject. Of these thirty-one cases, twenty-three patients died and eight recovered. The vast majority of the cases occurred in immediate association with pneumonia (twenty-eight out of thirty-one), the symptoms of arthritis usually following the onset of the pneumonia at intervals varying from a few days to a fortnight. In two instances the arthritis is said to have preceded the pneumonia. The affection is essentially one of adult and advanced life and is far commoner in men than in women. Both these peculiarities may stand in relation to the predisposing influence of previous damage of the joint. The arthritis is commoner in the upper extremity than in the lower. In twenty-seven of the thirty-one cases, one or more of the joints suppurated. In all the cases included in the table, with one exception, the pneumococcus was demonstrated in the fluid in the joints. But it is highly probable that cases occur in which the arthritis is due to the toxins produced by the pneumococcus elsewhere in the body. Many cases of supposed rheumatic fever may thus be due, in reality, to pneumococcus infection.

The morbid anatomy of the joint infected by pneumococci is essentially that of any other septic arthritis. The arthritis is especially liable to be located in a joint previously damaged, whether by disease or mechanical injury.

The symptoms may vary in severity from pain and slight swelling limited to a single joint, to an intense inflammatory œdema of the whole neighborhood of the articulation or of a whole limb, with severe pain, heat, and redness, with abnormal motility from destruction of the ligaments, and with grating of the bared surfaces of the bones. The fever is generally high. The nature of the arthritis can be determined only by its association with pneumonia and by bacteriological examination of the joint contents. The prognosis is grave both as regards danger to life and the ultimate restoration of function to the joint. In the cases that recover, progress is slow, extending over many weeks, and the function of the joint is, as a rule, permanently impaired. In suppurative cases there should be no hesitation in practising aseptic incision of the joint, with flushing, drainage, and fixation. And even in cases of serous effusion it may be questioned whether an arthrotomy for the removal of the morbid products, avoiding important ligaments and tendons, would not be followed by a speedier cure and more favorable result as regards the ultimate restoration of function to the joint; while at the same time one possible source of generalized infection would be largely removed. In any case, convalescence is apt to be tedious and prolonged with much stiffness and adhesion in and about the articulation.

A Case of Siriasis. By A. E. Griffin, M. R. C. S.—By "siriasis" is meant the condition of intense pyrexia developed by prolonged exposure to a heated atmosphere, and which is not to be confounded with that of simple "heat exhaustion."

The author reports the case of an assistant engineer on a Red Sea steamship, who had been working in the engine room at a temperature of 114° F., and who was found unconscious in his bunk an hour later. His temperature was 108.6° F., respiration 60, and pulse 180 to the minute. He was packed in an iced sheet and digitalis was administered hypodermically, with the effect of reducing his temperature to 103° F. He did not recover consciousness for twenty-four hours, and his temperature ranged from normal (after ice packs) to 103° F. for a week. The reflexes were at first absent; later they were exaggerated. Some tremor of both the upper and lower extremities persisted for months after his recovery. There was no evidence of any focal lesion.

Dorsal Dislocation of the First Phalanx of the Little Finger. By H. L. Barnard, F. R. C. S.—The author reports a case of this injury, and sums up his conclusions as follows: 1. That dislocation backwards of the first phalanx of the little finger is rarer than that of the index finger and much rarer than that of the thumb. 2. That, unlike the similar dislocation in the thumb, it is probably produced in most cases by violence applied to the dorsal surface of the head of the metacarpal bone. 3. That the three varieties—(a) incomplete dislocation; (b) the complete single dislocation; and (c) the complete complex dislocation, so admirably described by Farabœuf in the case of the thumb—apply equally to the little finger. 4. That the incomplete dislocation is easily reduced by pushing the phalanx forward; the complete simple form by the method of manipulation described by Farabœuf; whilst the complete complex dislocation, the result of ill-directed manipulation, requires the simple operation suggested by Desault, Farabœuf, and Hulke.

The Treatment of Dupuytren's Contraction and other Points in the Surgery of the Hand. By A. H. Tubby, F. R. C. S.—Contraction of the palmar fascia is an affection of insidious onset and slow but sure progress. Certain points stand out clearly: (1) it is more common in men than in women; (2) it is met with generally after forty years of age; and (3) a large number of the patients who suffer from it have a gouty history. Crystals of urate of soda have been found imbedded in the affected structures. About fifty per cent. of the patients can trace the onset to a slight injury or repeated rubbing of the hands. No bacteria have ever been demonstrated in the tissues. The method of treatment by multiple, subcutaneous tenotomy has certain disadvantages, so that in suitable cases the author dissects out all the affected fascia in the palm. The advantages of this latter method of operating are: (1) all the affected fascia can be completely removed and there is no tendency to recurrence; (2) the treatment is shortened; (3) no expensive apparatus is necessary, thin, narrow, malleable iron splints being all that are required. The disadvantages are the necessity for prolonged dissection and the danger of septic infection.

Club Hand.—Morphologically, the cases of club hand may be grouped thus: 1. The skeleton is complete and well-formed otherwise, the malformation consisting in a modification of the relations of the articular surfaces. 2. The skeleton is complete but deformed in parts, the radius is often shortened and the carpal bones atrophied.

This is the usual variety. 3. The skeleton is incomplete and deformed. Unfortunately, this deformity does not admit of very successful treatment.

Failure of union after division of a tendon is dependent upon: (1) the index of tension at which the muscle and tendon are set—*i. e.*, their powers of retraction; (2) the limitation of retraction of the tendon by bands of fibrous tissue binding it in its grooves; and (3) the character of the structures at the spot where division of the tendon occurs. A most important point is to keep the wrist fully flexed for at least four weeks after the accident and then gradually bring the hand into the straight position, taking at least a month to do so.

Loss of the Left Forearm by Amputation; Death Forty-nine Years thereafter; Necropsy; Localized Area of Atrophy at the Base of the Right Second Frontal Gyrus. By Dr. P. Maclulich and Dr. E. Goodall.—The authors report the case of a man, aged sixty-three years, whose left arm had been amputated forty-nine years previously. He died suddenly from angina pectoris. At the necropsy, on removal of the pia mater, a patch of softening, roughly oblong, about one and a half centimetres in length and from three quarters to one centimetre in breadth, was found occupying the gray matter of the brain at the base of the second right frontal gyrus, where it joined the ascending frontal. It was ochre colored. The disorganized tissue was thin, wrinkled and wasted. There had never been any fits or convulsive movements. It would be contrary to all experience to correlate the cerebral lesion in this case with the loss of the hand and forearm, on account of the forward position of the lesion. That it was due to atheroma would be highly improbable.

A Case of Chronic Inversion of the Uterus of Seven Months' Duration Successfully Treated by Aveling's Repositor. By Dr. T. Oliver.—The author reports a case of the above-mentioned affection, occurring in a woman aged twenty-four years, in which taxis under the influence of an anæsthetic had failed to replace the organ. Aveling's repositor was applied, the vagina was packed with iodoform gauze, and the suspenders of the instrument drawn together. It was left *in situ* for three days, the bands being tightened daily. When the repositor was removed the inversion had entirely disappeared, the steady and continuous pressure of the instrument having accomplished what forcible taxis failed to do. The restoration of the uterus to its normal position was permanent and was quickly followed by signs of improvement in the general health of the patient.

The Relation of the Bowel Lesion of Typhoid Fever to the General Symptoms of the Disease. By Dr. T. J. MacLagan.—The action of the typhoid bacillus is a dual one: (1) there is the specific local action of the parasite on the intestinal glands; and (2) the general action of the organism on the blood and tissues. The bowel lesion does not cause the fever and the fever does not cause the bowel lesion. They are conjoint results of the double action of the bacillus. It is the organic growth in the tissues of vast hordes of typhoid bacilli that causes the fever and general disturbance noted in typhoid fever. The cause of the wasting of the nitrogenous tissues is the consumption by millions of bacilli of the nitrogen destined for tissue nutrition. Similarly, the thirst, dry skin, and scanty secretion of urine are due to the consumption of the same bacilli of the water destined for the tissues. The increased metabolism which necessarily results from this action in the minute structure of the nitrogenous

tissues, the chief seat of heat formation, is the cause of the rise of temperature and of the quickening of the circulation. Recrudescences of the fever indicate either the invasion by the bacilli of one or more fresh glands or of a fresh absorption of septic material.

Though all the symptoms of typhoid fever are ultimately to be traced back to an action started by the typhoid bacillus, not one of its serious symptoms or special dangers is due to the direct action of that bacillus. The dangers attendant upon the bowel lesion (hæmorrhage and perforation) are due to the processes of sloughing and suppuration. The high temperature and feeble cardiac action are due to the superadded growth of the millions of cocci absorbed into the system from the sloughing glands.

British Medical Journal, January 12, 1901.

Observations on Wind Exposure and Phthisis. By Dr. W. Gordon.—The author has acquainted himself with the distribution of the phthisis death rate in Devonshire, especially with reference to the relative exposure to wind of the various parishes and districts. He concludes that the paramount influence which now determines a higher or lower rate of phthisis mortality is the degree of exposure to or shelter from the west and southwest winds. So that in the climatic treatment of phthisis, the choice of sufficiently wind-protected localities, where the patient's whole time can be spent in a tranquil atmosphere, is of the greatest possible importance. The author's article is accompanied by numerous tables, showing the phthisis death rates, the influence of shelter from west and southwest winds, and of soil, in the various districts of Devonshire, which go far to support his assertions. In none of the districts do definite differences in race, character of dwellings, occupation nor closeness of inter-marriage exist.

Jaundice in Typhoid Fever. By G. Ogilvie, M. B.—Jaundice is generally considered a rare and grave complication of typhoid fever. The author has met with three cases of typhoid fever with jaundice, in two of which, at least, the icterus must be considered as produced by the typhoid process. In the first case the jaundice was present from the beginning of the disease, and persisted until the patient became convalescent. In the second case the jaundice appeared on the fourth day after admission, apparently at the end of the first week of the disease; it again gradually disappeared as the temperature fell, and lasted nearly through the whole of the disease. In the third case, the jaundice preceded the onset of the enteric fever by several weeks and lasted during the first three weeks of its course. All three cases recovered.

The frequency of jaundice in typhoid fever is between one and one and one-half per cent. Clinical and pathological evidence alike seem to prove that catarrhal jaundice in typhoid fever, so far from being the rule, is an exceedingly rare occurrence. The first two cases herein reported were certainly not catarrhal in nature. But the precise seat and nature of the affection, as well as the reasons why the infection occasionally attacks the liver at so early a stage, and why it, all the same, runs a mild course, while in others the implication of the liver quickly leads to a fatal termination, are questions which in the present state of our knowledge must remain unanswered.

Influenza and the Nervous System. By J. Carslaw, M. B.—The author reports four cases of acute meningitis, which he thinks were influenzal in nature. Only one of the four patients recovered. The points to which he specially draws attention in all the cases, are as follows:

The illnesses occurred in otherwise healthy subjects and at a time when influenza was present in the neighborhood. Some of the cases had early catarrhal symptoms, considered by their medical advisers to be of the nature of influenza. In all, severe headache was prominent, and grave cerebral symptoms developed with alarming rapidity, and with no apparent cause, in the ears or elsewhere. They were all characterized by very restless delirium, with, in the main, little or no paresis of limb or ocular muscle to indicate any important localization. Most likely, the meningitis was more vertical than basal, though in the only case that was examined *post-mortem* the purulent exudation was found very prominently both at the base and on the convexity, and in this case there had been prominent clinical facts in regard to the pupils, ptosis, and strabismus, indicating that the base of the brain was involved.

The Detection of Arsenic in Beer and Brewing Material. By S. Delépine, M. B.—The author gives a short account of the methods of analysis for the detection of arsenic in beer and brewing materials, used by him during the recent epidemic of arsenical neuritis in Manchester. After discussing the wide distribution of arsenic in Nature, and the various methods for its detection, he describes his own method. After depositing the arsenic on copper by Renisch's method, it is oxidized and sublimed upon cover-glasses, when, by microscopical examination, the triangular crystals of arsenious acid can be readily recognized.

A Note on the Value of Inoculation against Enteric Fever. By H. Cayley, F. R. C. S.—The author gives the results of the inoculations against typhoid fever of members of the staff and establishment of the Scottish National Red Cross Hospital, serving in South Africa. The members of the first section of the hospital, sixty-one persons in all, were inoculated twice at an interval of about ten days. In many cases the symptoms were just as severe after the second as after the first inoculation.

There was not a single case of typhoid amongst the *personnel* of this first section. The second section of the hospital, comprising eighty-two persons, was inoculated on board ship, but many of them only once. The material for inoculation had been on board for some time, and was not so fresh as in the first instance. Of the second section, one nurse and five orderlies had typhoid fever at Kroonstadt, of whom two died. Of these six, there were two inoculated (once) and three non-inoculated. Of the two who died, one had been once inoculated, the other had not been inoculated. A third section, consisting of twenty persons, were all inoculated and none of them had the disease. Examination by means of the Widal test four months later, gave the following results: of the first section, the blood of twenty-three individuals was tested, with positive results in twenty-one instances; of the second section, the blood of twenty-two was tested, with positive results in only two instances.

The results above given are very strong evidence in favor of the protective power of the antityphoid inoculation, when the inoculations are very carefully performed, and they point to the necessity for two inoculations at a suitable interval. During the period of five months that the hospital was stationed at Kroonstadt there were ninety-two admissions for enteric fever and eleven deaths. Of the ninety-two cases, fifteen said they had been inoculated, a few were doubtful, and about seventy had not been inoculated. Of the eleven deaths, one had been inoculated once, the others had not been inoculated. The author is convinced that the attacks of typhoid fever were, as a rule, much milder in the inoc-

ulated than in the non-inoculated, and the duration of the disease was much less.

The Toleration of Arsenic. By R. W. MacKenna, M. B.—The author's article is based upon a table of forty-eight cases of various skin diseases, in which arsenic was given over long periods of time, without any untoward symptoms appearing. The arsenic was given in the form of Donovan's solution of the double iodide of arsenic and mercury. The table shows that some patients had taken daily 0.409 grain of arsenious acid without any harmful effects. A consideration of the statistics forces one to the conclusion that an undue importance has been attached to the arsenic in the beer drunk by the sufferers in the recent epidemic of peripheral neuritis in Liverpool and Manchester. Only those cases should be ascribed to arsenic in which there was a well-marked clinical picture of arsenical toxæmia, or in which arsenic was found in the excretions, or *post-mortem* in the organs of the body.

Indépendance médicale, January 2, 1901.

Hæmorrhagic Form of Influenza.—M. N. P. Bénaky describes a grave form of influenza, terminating fatally, characterized by hæmoptysis, epistaxis, metrorrhagia and subcutaneous and submucous hæmorrhages. The patient was undoubtedly suffering from influenza and the bleedings could not be traced to any other source.

Curetage in Uterine Infection.—M. J. Thiénot believes in curetting for uterine infection following abortion or labor. The details of the operation do not differ from those in general use. Anæsthesia is always given. General tonic and supporting treatment is recommended at the same time.

Gazette hebdomadaire de médecine et de chirurgie, December 27, 1900.

Mammary Tuberculosis.—M. Edouard Pluyette reports a case. He says that the germs may gain entrance through abrasions of the nipple. In this case the glandular tissue was entirely destroyed, and gave evidence of tuberculous infection, while the lacteal canals presented only ordinary inflammation. The disease progresses rapidly. There was retraction of the nipple, but no external evidence of disease was noticed until the whole gland was involved. The prognosis is good if early operation is performed.

Lyon médical, December 23, 1900.

Clinical Significance of the "Choc en Dome."—M. J. Mollard says that this sign is not infallible in aortic insufficiency and does not deserve an important place in the semeiology of the disease, as it is frequently absent. It may even be present in other cardiac diseases than aortic and mitral insufficiency and the chronic myocarditides.

Treatment of Two Cases of Diabetes with Serum from the Pancreatic Vein.—M. P. Chatin and M. L. Guinard have treated two well-marked cases of diabetes mellitus by this method and have made daily observations on the amount of sugar present in the urine. Their results have been totally negative. They conclude that this method of opotherapy is useless. It is possible, they think, that the pancreatic products are carried away by the lymphatics rather than by the veins.

Spontaneous Rupture of the Biliary Passages, Laparotomy; Recovery. By M. M. Lagoutte.

Presse médicale, December 22, 1900.

Hæmostatic Medication.—M. H. Vaquez writes a review of the recently introduced glandular extracts for hæmostatic use. He says that while the recorded facts as to their employment are interesting, the scientific results are not yet well established. While these substances have led to their empirical employment, it is probably only a question of time before their use will rest upon a scientific basis.

Agglutination of Colon Bacilli by Typhoid Serum.—M. Paul Courmont and M. C. Lesieur have found that the serum of twenty-two typhoid patients agglutinated feebly pure cultures of the *Bacillus coli communis*, while typhoid bacilli showed the reaction in varying degrees with the same sera, usually very intense. They conclude that the serum of typhoid patients which agglutinates Eberth's bacillus, has not influence ordinarily upon the colon bacillus. When the latter shows the reaction it is usually very feeble and does not compare with the intensity of the agglutinative action of the typhoid bacilli.

December 26, 1900.

Hypertrophic Blennorrhagic Periosteitis.—M. Hirtz and M. Delamare report such a case in which the femoral diaphysis was the seat of the lesion. The authors consider the condition similar to that of the so-called gonorrhœal rheumatism. The diagnosis in this case was established by means of the Röntgen rays.

Berliner klinische Wochenschrift, December 24, 1900.

Normal and Pathological Histology of the Human Hypophysis Cerebri.—Dr. C. Benda has made numerous examinations of the normal and diseased hypophysis in man. In four cases of acromegaly he has found it enlarged, and in two instances the seat of a tumor. He hesitates, nevertheless, from drawing the conclusion that the enlarged gland is responsible for the growth of the bony system.

Serpentine Aneurysm of the Spinal Vascular System.—Dr. Felix Brasch records such a case in which the abnormality of the spinal blood-vessels evoked the most unusual and peculiar complex of symptoms.

Extirpation of the Hypophysis Cerebri. By Dr. Friedrich F. Friedmann and Dr. Otto Maas. An experimental study.

Amyloid Degeneration, especially of the Kidneys. (*Conclusion*).—Dr. M. Litten says that in the majority of instances of amyloid kidney, the urine is clear, abundant, of light yellow color, and of low specific gravity. There is no other renal disease in which different cases show such a variance in quantity excreted and in inorganic constituents. The presence of albumin is by no means a certain sign of amyloid degeneration; it may or may not be found, although with the large white kidney due to amyloid degeneration, immense quantities of albumin are excreted. [The whole article should be read by those interested].

Centralblatt für Chirurgie, December 15, 1900.

Surgery of the Nose. By Dr. Ludwig Löwe.—A description of the technique of, and indications for, opening the skull to operate upon its base, and for the removal of diseased tissues from the nasal cavities.

December 29, 1900.

Skin Transplantation for Severe Stenosis of the Larynx and Trachea.—Dr. H. Alopky has used Gersuny's suggestion to transplant skin in a stenosed larynx. He

has performed a fission of the larynx and trachea, excised the portion filled with scar tissue and covered in the defect with skin. The patient recovered well, with good functional power.

Wiener klinische Rundschau, December 30, 1900.

Significance of the Presence of Acetone in the Urine.—Dr. Waldvogel says that while the origin of acetone as it appears in the urine is not perfectly clear, its presence is significant of inanition or of diabetes mellitus. Acetonuria following chloroform or ether narcosis is due to an intensity of fat metabolism.

Tuberculosis Pseudoleucæmica.—Dr. Enrico Ferrari and Dr. Vittorio Ceminotti say that some cases which clinically resemble pseudoleucæmia, are in reality tuberculous in nature, representing a tuberculosis of the lymphatic apparatus. They report a case with histological findings which agree with those reported in literature, except that the authors also found the peculiarly characteristic cells in the muscle-tissues.

Ætiology of Early Ulcerative Syphilide. (*Continued article.*) By Dr. Jaroslav Bukovsky.

Wiener klinische Wochenschrift, December 27, 1900.

Contribution to the Study of Thomsen's Disease. Dr. Julius Mahler records minutely a case of myotonia congenita (Thomsen's disease). Myotonic movements were present. On passive motion there was no muscular contraction, the muscles feeling neither hard nor soft. The muscles of the trunk, the extremities, and the masseter and tongue musculature, were affected. From a study of his patient, the author concludes that this disease is of spinal origin.

Extirpation of the Spleen.—Dr. Karl Schwarz reports a case in which the spleen was removed. The organ was hypertrophied and was freely movable. The patient made a good recovery.

Centralblatt für Gynäkologie, December 15, 1900.

Autocystoplastic and Colpocystoplastic Operation.—Professor O. Witzel reports a very difficult operation performed for the relief of a large defect in the vesicovaginal septum, in which he employed as flaps, part of the bladder wall and part of the vaginal wall, with a perfect result. The vaginal cavity is greatly reduced in size, but is sufficiently patent to allow the passage of a catheter. The uterus was removed, as the woman was above fifty years of age. A slight modification of the procedure could be performed on a woman still capable of bearing children, giving her practically a normal vagina.

Beneficent Influence of Pregnancy upon Enteroptosis.—Dr. Hector Maillart says that when the uterus reaches a certain size, the intra-abdominal pressure is heightened, thus relieving many of the digestive and neurasthenic symptoms of enteroptosis. The patient gains in weight and feels encouraged by this quasi cure, which may be permanent.

Cure of Probably Tuberculous Bilateral Salpingitis by Ligature of Blood-vessels. By Dr. Max Nassauer.—A polemic article.

Wiener medizinische Blätter, December 27, 1900.

Usual Forms of Pneumonia in Children.—Dr. M. Marfan says that lobar pneumonia in children is of the same pathogenesis and clinical course as it assumes in adults, except that the symptomatology differs somewhat in the former. There are an initial chill, a short cough, and dyspnoea, and frequently pain is complained of in the upper abdominal regions. Bronchial breathing and

crepitant râles appear later in children than in adults, which may be accounted for by the fact that, in children, pneumonia often begins as a central process. The right apex and the left base seem to be the favorite spots of localization. The characteristic symptoms may not be seen for four or five days after the onset and the diagnosis is, therefore, at times, difficult.

Deutsche Aerzte-Zeitung, January 1, 1901.

Pleural Effusions in Heart Disease.—Professor D. Gerhardt narrates the clinical histories of a number of such cases. He says that, theoretical considerations aside, there are a number of patients who have cardiac disease, especially of the myocardium, who have effusions into the pleura which seem to have some dependence upon the basic disease. The prognosis is not favorable, being about the same as that of cutaneous dropsy seen in heart disease. Digitalis seems to be the most efficacious drug, but occasionally the effect of the drug is not evident until part of the fluid has been evacuated by puncture.

So-called "Poison Primulæ." By Professor R. Kobert.

Significance of Eosinophile Cells in Tuberculous Sputum. By Dr. Franz Meyer.

On Xeroform. By Dr. Alfred Japha.

Riforma medica, December 15, 17, and 18, 1900.

Concerning a Case of Friedrich's Unilateral Polyooclonus. By Dr. Clemente Ferraris.

Concerning a Case of Fibroma of the Tongue. By Dr. Eugenio Arcoleo.—The patient was a man aged twenty-six years. Six years before admission he noticed accidentally a small tumor on the surface of the tongue. It was red in color and of the size of a pea. The tumor gradually grew and finally impeded mastication. There was no history of syphilis. On examination the tumor was found to be situated in the median line on the base of the tongue, and to have reached the size and shape of a mulberry, with an irregular surface, red in color. On palpation it was movable on the surface of the tongue, on which it was implanted by means of a short pedicle. It was not sensitive and was hard in consistence. The submaxillary and cervical lymphatics were not enlarged. The tumor was removed, and the wound healed on the sixth day. On microscopic examination it was found to be a fibroma.

Concerning Two Cases of Leprosy in the Province of Pesaro-Urbino. By Dr. Goffredo Ungaro.—The purpose of the author is to contribute to the statistics relating to the diffusion of leprosy in Italy.

December 19, 20, 21 and 23, 1900.

The Semeiology of the Pulse in the Foot. By Dr. M. Crispino.—The author describes the application of sphygmography to the pulsation of the arteries of the foot. He has tested the value of this diagnostic measure in health as well as in various arterial and cardiac diseases, and concludes that it is very useful in determining the condition of the circulation. The tracings obtained were clear, constant, and characteristic. He has succeeded in improving Tatti's method of "pedography" by devising an apparatus which records the pulsations directly, instead of indirectly, as in that employed by Tatti.

Vratch, December 2 (O. S. 14), 1900.

Concerning the Influence of the Statutory Limit of Appropriation on the Development of Zemstvo Medicine. By Dr. D. N. Jbankoff.

Concerning the Relation between Bubonic Plague and other Forms of Hæmorrhagic Septicæmia. By Dr.

S. V. Konstansoff.—The author's conclusions are as follows: (1) active artificial immunity against chicken-cholera or hog-cholera has no influence upon the course of a subsequent bubonic plague infection; (2) in the same manner, passive immunity against bubonic plague has no effect on infections with the germs of the aforementioned diseases; (3) the absence of an interrelation of immunity between bubonic plague and other hæmorrhagic septicæmias speaks for a special position of bubonic plague in this group of diseases; (4) antibubonic serum may be used with success as a diagnostic measure for the determination of the presence of bubonic plague; (5) there is a marked difference between closely related germs of hæmorrhagic septicæmias, particularly as regards their resistance to the temperature of 45° C. (113° F.)

Schleich's Method of Anæsthesia in Operative Surgery. By Dr. V. E. Neschel.—The author reports a number of cases operated on under anæsthesia according to Schleich's method. He says that this method of local anæsthesia is a real boon to country practitioners, who are often obliged to operate without any medical assistance. In the four cases which he reports, he performed suprapubic cystotomy without any trouble, so far as the anæsthesia was concerned, except that in one case the patient became restless toward the end of the operation, and chloroform had to be given.

The Appearance of Plague in the Territory of the Eastern Chinese Railway. By Dr. V. P. Avroroff.—An account of an epidemic of plague which occurred in the Chinese towns of Inkoy and New-djuang in the summer of 1899.

Proceedings of Societies.

AMERICAN LARYNGOLOGICAL ASSOCIATION.
Twenty-second Annual Congress, Held (in Conjunction with the Congress of American Physicians and Surgeons) in Washington, on Tuesday, Wednesday, and Thursday, May 1, 2 and 3, 1900.

The President, Dr. SAMUEL JOHNSTON, of Baltimore, in the Chair.

(Continued from Vol. lxxii, page 1119.)

On the Employment of the Upright Position in Ether Operations upon the Nose, Throat, and Ear.—This was the subject of a paper by Dr. THOMAS R. FRENCH. (See page 621.)

Severe Hæmorrhage after Operations on the Throat and Nose. A Report of Five Cases.—Dr. ARTHUR A. BLISS reported these cases. (See page 406.)

Secondary Hæmorrhage Following the Use of Suprarenal Extract.—This was the title of a paper by Dr. F. E. HOPKINS. (See page 315.)

Dr. W. P. PORCHER, of Charleston: I should like to ask the essayist how he prepares the suprarenal extract, and whether he makes it fresh every day.

Dr. HENRY L. SWAIN, of New Haven: The subject of secondary hæmorrhage has greatly interested me. If we look at this matter from the standpoint of the anatomy of the turbinated tissues and septum on which we operate, we can readily see that we must have some hæmorrhage following the use of these two agents together or with either alone. As Dr. Hopkins has pointed out, we have more hæmorrhage when they are combined than with either one alone. In any case the hæmorrhage is

stopped merely by the presence of the circular fibres in the blood-vessels, which are made to contract. Any coagulating agent put upon the surface increases the coagulability of the clot, but then there is nothing which prevents hæmorrhage any more than in the ordinary wound, except that the vessels are contracted by the action of the circular muscular fibres. Unless that is kept up, relaxation will take place. If we have a small clot stopping up a blood-vessel, and the blood-vessel increases to four times its size by relaxation, the clot is no longer big enough to plug the opening. The question, then, arises, How much more hæmorrhage do we have in these cases than without the use of the suprarenal extract? I have not been able to minimize the hæmorrhage I have seen after operations, as some of the other gentlemen have done who have been quoted.

I remember particularly one hot summer night, two years ago, having an alumnus of Yale come to consult me for the purpose of having an exostosis removed from his sæptum. He said it was necessary to have it done that night, as he was going to take the train for home the next morning. I told him I would do the operation for him. I had used all the suprarenal extract I had in a previous operation a few moments before. I operated on him and used cocaine. There was very profuse hæmorrhage, which gave me much concern for three-quarters of an hour. Finally I succeeded in controlling the hæmorrhage, but the patient was awakened three times in the night by bleeding. He got up and went through various operations of his own suggestion with a view to stopping it and managed to control the hæmorrhage. The patient operated upon with the suprarenal did not have any trouble at all. Perhaps, with this picture in my mind and those of other cases in which the suprarenal extract was used, my opinion has been somewhat warped.

Dr. JOHN W. FARLOW, of Boston: I have used the suprarenal extract in many cases, and have not seen any trouble following its use in my own work, but I have heard some of my assistants speak of severe secondary hæmorrhage in several instances. Even if there is a possibility of such a hæmorrhage, it is such a great advantage to be able to do a practically bloodless operation, for instance, in removal of sæptal spurs, that we must certainly admit the very great value of the extract. We can see readily into the nose unobstructed by blood, and are able to complete the operation and place a pledget of gauze to control any possible hæmorrhage in a much more satisfactory manner than when the blood interferes with our sight, and we are obliged to grapple more or less in the dark.

As regards its use in causing coryza, I have seen some noses very much irritated by it, and more instances in which the action of the extract caused a decided diminution in an already irritated nose.

As an example of its very beneficial effect, I recall the case of a boy eight or nine years of age, who was well in all respects except that he had very frequent and incapacitating headaches, for which no cause could be found, although he was examined for malarial disease, for poisoning with arsenic, lead, etc., and for possible defect of vision. There was some deviation of the upper part of the sæptum, with pressure against the middle turbinal. An application of the suprarenal extract to the upper part of the nose caused an almost magical disappearance of the headache. He experienced the same relief on several later occasions, and after he had used it more or less frequently for about two weeks the headaches entirely disappeared and have not returned, although he had suffered for eight months. It is now more than three months

since there has been any need of using the extract, for there has not been the slightest suspicion of pain in the head.

Dr. A. W. WATSON, of Philadelphia: I have not had much experience in using the suprarenal extract in connection with my operative work. I have found cocaine to be efficient enough. But, as to the question of hæmorrhage after the use of suprarenal extract, it has struck me that the reason for this secondary hæmorrhage is that the relaxation which takes place after the use of the extract is delayed. The relaxation following the use of cocaine takes place within half an hour, as a rule, and it has been my practice to keep the patient under my control in my office until the relaxation has come on and there is no sign of hæmorrhage. In this way a clot is formed when the vessel is dilated. Of course, if the clot is formed earlier it will not be large enough, as Dr. Swain has just said, for the vessel, consequently hæmorrhage is very apt to occur. If sufficient time is allowed for the formation of the clot, when the patient goes home the increased action of the heart is not sufficient to force the clot out through the dilated vessel. With regard to the suprarenal extract causing acute coryza or inflammation in the nose, I have not seen it do so in ordinary cases. But I had an experience myself, not very long ago, which would suggest that it could do so, not by its physiological effects, but from the possibility of its having undergone decomposition in the nose. I had a severe coryza some time ago, and after the acute symptoms had subsided relaxation took place, so that my nose was stopped up and was in an uncomfortable condition. This was about two weeks after the beginning of the attack. I used the suprarenal extract to reduce the turgescence, in which it was very effective. But in less than twenty-four hours thereafter I had an acute inflammation of all the accessory sinuses. Quite a discharge came from the antrum and other sinuses, which lasted for about a week. The solution used was a fresh extract, and was used only during one day. The extract did not decompose during the time that it was in use, so far as appearance and odor would indicate.

Dr. FARLOW: I should like to ask if any of the members are familiar with the preparation which Dr. H. L. Wagner, of San Francisco, showed at our meeting two years ago. I have tried to find it in the market, but have been told that no such preparation was to be obtained.

Dr. JAMES E. NEWCOMB, of New York: I desire to say that Dr. Wagner gave me a little of his preparation, which I put on my shelf and kept some months before I opened it. When I did open it there was a distinct putrefactive odor, although the phial was apparently well sealed. It was entirely unfit for use.

Dr. SWAIN: I believe that if the fresh glands can be obtained, it is possible to make a solution of their active principles in very dilute acetic acid, and that this solution can be put up in sealed glass tubes and kept indefinitely, giving one a perfectly fresh solution at all times.

Dr. HOPKINS: I have nothing to say except reply briefly to the remarks of Dr. Porcher. I have not followed one rule in making the solutions. I first used sterilized water, and later antiseptic solutions, and in neither case did it seem to make any particular difference.

Dr. PORCHER: Do you prepare the extract fresh every day?

Dr. HOPKINS: I did at first with sterilized water, and this fresh solution was just as irritating; later I used

an antiseptic solution, and this was as well tolerated and effective after a considerable period.

The object of my paper was to call attention to the fact that secondary hæmorrhage seemed to occur more frequently than we had been led to believe, but not in any way would this seem to me to contra-indicate the use of the extract; it would only show that we should exercise more care in the after-treatment of our patients.

A Case of Ozæna of Probably Sphenoidal Origin.—

This case was presented by Dr. J. W. FARLOW. (See page 534.)

Dr. J. E. LOGAN, of Kansas City: I have been much interested in Dr. Farlow's paper because my experience coincides with his in at least two cases which I have had of a similar nature. I have never been able to gain access to the body of the sphenoid in the manner suggested. One case I have in mind was unilateral, in which large, foul crusts would form. I operated and gave relief by opening the posterior ethmoidal cells. The patient from time to time complains of some crust formations in the upper portion of the posterior nares, suggesting to my mind that possibly the body of the sphenoid was involved. The case reported by Dr. Farlow and the relief obtained by his treatment only go to prove what I have often thought and advocated, and that is, that these particular pathological phenomena characterizing atrophic rhinitis are secondary to sphenoidal, ethmoidal, or frontal-sinus inflammation, developed there by conditions of deformity, climatic influences, or the like, and that the relief is to be found in proper attention to these accessory sinuses.

Dr. SAMUEL W. LANGMAID, of Boston: I have seen five cases of acute sinus inflammation within two weeks. In the forenoon of the day I left Boston to attend this meeting, I had the case of a gentleman who had suffered great pain for several days. There was very little frontal pain. He came to my office for relief, and after cocainizing the parts I used a probe, with the consequent discharge of considerable bloody mucus. Some of it contained purulent matter. There is no doubt that influenza is the cause of much sinus trouble. If the inflammation of the mucous membrane subsides quickly and if the obstruction in the orifices of the outlets of the sinuses is removed quickly, there may be nothing left. The case would simply be an acute one which would go on for perhaps forty-eight or sixty hours. Occasionally we observe cases of chronic sinus trouble as the result of influenza. Many such cases have occurred as the result of the last epidemic of this disease. We ought in every case to ascertain the condition of the sinuses and not be content with simply spraying the nose. By opening these sinuses in a gentle way, we may guard against the development of chronic trouble.

Dr. A. W. WATSON, of Philadelphia: I am very glad to have heard the paper of Dr. Farlow, as it confirms my own views on this subject. I have been in the habit for some time of looking upon all cases of ozæna as occurring independently of atrophy—that is to say, there may be atrophy of the nose without the ozæna, without crusts, or with crusts without ozæna. We see many such cases. I have seen cases in the same family, in which one child would have a severe ozæna, while in examining another child I would find a case of atrophy, and cases without any ozæna at all and but few crusts, or with crusts without ozæna. It has been my experience that cases of ozæna are due to infection of the accessory sinuses, particularly the sphenoid and posterior ethmoid cells. I have for some time, as a routine measure, washed out these cells and the spaces between them, that is, the posterior spaces,

behind the superior and middle turbinates and in front of the sphenoid, with a curved or straight cannula that will pass into the sphenoid cells themselves, and I have had good results. In a paper read before the Laryngological and Otological section of the College of Physicians of Philadelphia, I mentioned this method of treating atrophic rhinitis, and my results have been good. I have had many obstinate cases of many years' duration which were relieved by this method, the patients remaining free from odor when seen at long intervals afterward. I have been using a weak solution of formaldehyde in an alkaline solution, but I think the chief point in the treatment consisted in washing out the cells and spaces in the posterior region.

Dr. FARLOW: There is one point in the treatment of these diseases which is important, and that is, after the nose is thoroughly cleansed, the patient should be asked to remain in the waiting-room without blowing the nose, with the head in the upright position. After a while the nose should be examined again, when, possibly, we may get a clue to the source of the secretion.

(To be continued.)

Book Notices.

A Text-book of the Practice of Medicine. By JAMES M. ANDERS, M. D., Ph. D., LL. D., Professor of the Practice of Medicine and Clinical Medicine in the Medico-chirurgical College, Philadelphia, etc. Illustrated. Fourth Edition, thoroughly Revised. Philadelphia and London: W. B. Saunders & Company, 1900.

WITH the exception of some few changes and additions, especially in the chapters upon disorders of digestion, the fourth edition of this able work is a repetition of the third. The reason for this is understood when we recollect that the third edition appeared only a year ago.

Therapeutics: Its Principles and Practice. By HORATIO C. WOOD, M. D., LL. D. (Lafayette-Yale), Professor of Materia Medica and Therapeutics, and Clinical Professor of Diseases of the Nervous System, in the University of Pennsylvania, etc. Eleventh Edition. Remodeled and in greater Part Rewritten by HORATIO C. WOOD, and HORATIO C. WOOD, JR., M. D., Demonstrator of Pharmacodynamics in the University of Pennsylvania. Pp. xxxi-850. Philadelphia and London: J. B. Lippincott Company, 1900.

IT must indeed be a small fraction of all American physicians who are unfamiliar with this classic work, and we should be much surprised if it did not form a part of the greater number of medical libraries in this country. Under these circumstances the eleventh edition needs no introduction from us and a review is almost as unnecessary. It may be well, however, to say that the present edition brings pharmacology to its most recent step, and that the arrangement of the material is such as to make the work even more available and useful than formerly.

The Theory and Practice of Hygiene (Notter and Firth). By J. LANE NOTTER, M. A., M. D. (Dub.), Fellow of the Chemical Society, etc., and W. H. HORROCKS, M. B., B. Sc. (Lond.), Assistant Professor of Hygiene in the Army Medical School, Netley, etc. Second Edition. Pp. xvii-1085. Philadelphia: P. Blakiston's Son & Company, 1900.

MANY changes and additions mark the second edition of this excellent book, as they have been required by the

advances in hygienics that have taken place in the past few years, but they are for the greater part inconspicuous and the volume as a whole is unchanged. The work is a thorough and exhaustive one, dealing with hygiene in all its branches; indeed, it is one of the ablest of its sort that have appeared in recent years.

A Manual of Materia Medica and Pharmacology. Comprising all Organic and Inorganic Drugs which are and have been official in the United States Pharmacopœia together with Important Allied Species and Useful Synthetics. Especially Designed for Students of Pharmacy and Medicine as well as for Druggists, Pharmacists, and Physicians. By DAVID M. R. CULBRETH, Ph. G., M. D., Professor of Botany, Materia Medica, and Pharmacognosy in the Maryland College of Pharmacy, etc. Second Edition, Enlarged and thoroughly Revised. With 464 Illustrations. Pp. xv-17 to 885. Philadelphia and New York: Lea Brothers & Company, 1900.

THE second edition of this work is the correction and elaboration of the first, and, as four years have elapsed between them, there has been some opportunity for revision. The character of the work, however, remains unchanged, and what we formerly had to say of the first edition applies now with equal force.

A Manual of Hygiene and Sanitation. By SENECA EGBERT, A. M., M. D., Professor of Hygiene and Dean of Medico-chirurgical College of Philadelphia, etc. Second Edition, Enlarged and thoroughly Revised. Illustrated with 77 Engravings. Philadelphia and New York: Lea Brothers & Company, 1900.

THE complete revision of the work, a moderate number of additions, and a chapter upon military hygiene distinguish this second edition from the first. The last-named chapter is disappointing in its brevity, but the work as a whole is one of much merit, in testimony whereof the rapid exhaustion of the first edition may be cited.

BOOKS, ETC., RECEIVED.

A Text-book of Pharmacology and Therapeutics, or the Action of Drugs in Health and Disease. By Arthur R. Cushny, M. A., M. D. Aberd., Professor of Materia Medica and Therapeutics in the University of Michigan, etc. Second Edition, Revised and Enlarged. Illustrated with Forty-seven Engravings. Pp. v-7 to 732. Philadelphia and New York: Lea Brothers & Company, 1901.

Handbook of Practical Hygiene. By D. H. Bergey, A. M., M. D., First Assistant, Laboratory of Hygiene, University of Pennsylvania. Pp. 164. Easton, Pa.: The Chemical Publishing Company, 1901. [Price, \$1.50.]

A Text-book of Urine Analysis for Students and Practitioners of Medicine. By John H. Long, M. S., Sc. D., Professor of Chemistry and Director of the Chemical Laboratories in the Schools of Medicine and Pharmacy of the Northwestern University. With Numerous Illustrations. Pp. iv-249. Easton, Pa.: The Chemical Publishing Company, 1901. [Price, \$1.50.]

Physicians' Manual of Therapeutics, referring especially to the Products of the Pharmaceutical and Biological Laboratories of Parke, Davis, & Company. Pp. 5 to 526. Detroit, Mich., 1900.

Anatomie générale appliquée à la physiologie et à la médecine. Par Xavier Bichat, Médecin du Grand Hos-

pice d'Humanité de Paris, etc. Première partie. Pp. 256. Paris: G. Steinheil, 1901.

La Insuficiencia Hepática. Por el Doctor D. Nicolás Rodríguez y Abaytúa. Discurso de recepción en la Real Academia de Medicina el 25 de Noviembre de 1900, seguido del Discurso de Contestación del Doctor D. Antonio Espina y Capo. Pp. 5 to 135. Madrid: Nicolás Moya, 1900.

Klinische und pathologisch-anatomische Studien zur Aetiologie des Uterusmyoms. Von Elis Essen Möller. Akademische Abhandlung. Pp. 106. Berlin: S. Karger, 1900.

Aetiologie und Prophylaxe der Lungentuberkulose. Von Dr. J. Ruhemann, Arzt in Berlin. Mit 13 Kurventabellen. Pp. 88. Jena: Gustav Fischer, 1900.

Die pathologische Anatomie im 19. Jahrhundert und ihr Einfluss auf die äussere Medizin. Von Professor H. Chiari in Prag. Pp. 16. Jena: Gustav Fischer, 1900.

Die Mechanik des Hörens und ihre Störungen. Von Dr. med. Gustav Zimmermann, Ohrenarzt in Dresden. Mit vier Abbildungen im Text. Pp. vi-110. Wiesbaden: J. F. Bergmann, 1900.

Experimentelle Untersuchungen über das Conserviren von Fisch und Fleisch mit Salzen. Von Alfred Pettersson, Med. Lic. Pp. 70. München: R. Oldenburg, 1900.

Experimentelle Untersuchungen über die Einwirkung des Eserins auf den Flüssigkeitswechsel und die Circulation im Auge. Von V. Grönholm, früherem Assistenten an der Universitäts-Augenklinik in Helsingfors, Finnland. Hierzu 2 Tafeln mit Curven I-XI. Pp. 620 to 711. Leipzig: Wilhelm Engelmann, 1900.

Der Stand der Volksheilstätten-Bewegung im In- und Auslande. V. Bericht. Herausgegeben von Dr. med. G. Liebe, in Braunschweig. Pp. 85. München: Seitz & Schauer, 1900.

Arzneiverordnungen in der Kinderpraxis. Für Studierende und Aerzte. Bearbeitet von Dr. med. H. Guttmann, prakt. Arzt in Berlin. Pp. 110. Berlin: S. Karger, 1900.

The Eighteenth Annual Report of the Mothers' and Babies' Hospital and Dispensary. From January 1, 1899, to October 1, 1900.

The Eighteenth Annual Report of the Harlem Eye, Ear, and Throat Infirmary of the City of New York, 1900.

Proceedings of the Washington Academy of Sciences. A Contribution to the Study of the Insect Fauna of Human Excrement. By L. O. Howard, Ph. D.

Neglected Clinical Opportunities in American Medical Centres. By S. A. Knopf, M. D. (Reprinted from the *Bulletin of the American Academy of Medicine.*)

Results of Five Years' Experience with Cooperation between State Hospitals for the Insane. By Peter M. Wise, M. D.

Injuries of the Eyelids and Eyeballs. By L. Webster Fox, M. D., of Philadelphia. (Reprinted from *International Clinics.*)

Indications for the Drainage in Diseases of the Biliary Passages and the Technic of Operation. By J. E. Summers, Jr., M. D., of Omaha. (Reprinted from the *Philadelphia Medical Journal.*)

Fibroma of the Ovary—Hernia or Diverticulum of the Chorion. By Leonidas N. Laidley, M. D., of St. Louis. (Reprinted from the *American Journal of Obstetrics.*)

A Cataract Knife of Excellent Shape and Proportion devised a Century and a Half ago, by Dr. Thomas Young, of Edinburgh, and the Knives which preceded it.

By Alvin A. Hubbell, M. D., of Buffalo. (Reprinted from the *Ophthalmic Record*.)

Abdominal versus Vaginal Hysterectomy. By Henry O. Walker, M. D., of Detroit. (Reprinted from the *Physician and Surgeon*.)

Is Internal Antiseptics Possible? By Thomas E. Satterthwaite, M. D. (Reprinted from the *Post-graduate*.)

A Clinical and Pathological Study of the Rash of Scarlet Fever. By Jay F. Schamberg, M. D., of Philadelphia. (Reprinted from the *Journal of the American Medical Association*.)

A Clinical Study of the Lymphatic Glands in One Hundred Cases of Scarlet Fever. By Jay F. Schamberg, M. D. (Reprinted from the *Annals of Gynecology and Pædiatry*.)

Miscellany.

The Pan-American Medical Congress.—Below we give the names of the American physicians who have so far announced their intention of reading papers before the third Pan-American Medical Congress, which will convene at Havana, Cuba, on February 4th, together with the titles of the papers:

SECTION ON MEDICINE.—Tuberculosis in Man and Beast, by Dr. John E. Kelley; Ætiology, by Dr. Elmer Lee; Physical Diagnosis, by Dr. W. H. Vandenburg; Remarks on Tuberculosis, by Dr. Liston H. Montgomery.

SECTION ON GENERAL SURGERY.—Operative Treatment of Prostatic Hypertrophy, by Dr. Ramon Guitéras, New York; The Bearing of Local Leucocytosis in Surgery, by Dr. R. T. Morris; Gangrenous Hernia, by Dr. T. H. Manley; Treatment of Varicose Ulcers, by Dr. J. L. Medina; Cocaine Spinal Anæsthesia, by Dr. G. R. Fowler; The Pronated Foot and its Effect upon the Knee Joint, by Dr. Michal Hope; Surgical Intervention in Uterine Fibroids, by Dr. A. Vander Veer; Remarks upon Post-operative Psychological Disturbances, by Dr. G. Tucker Harrison; Knee Joint Tuberculosis Differentiation in the Young and Adult, by Dr. J. D. Griffith; Operative Treatment of Inguinal Hernia, by Dr. A. M. Phelps; Some of the General Conditions and Features of Disability Attributable to Personal Accidental Injury, as well as Disability Due to Disease Following Bodily Injury, by Dr. L. H. Montgomery; Remarks on Inguinal Hernia, by Dr. Garmo. Papers, with titles to be announced, by Dr. E. G. Tuttle, Dr. J. W. Roberts, and Dr. W. P. Nicholson.

SECTION ON OBSTETRICS.—The Toxicity of the Urine in Pregnancy and its Relation to Puerperal Convulsions, by Dr. Milton J. Duff; Face Presentation, by Dr. J. A. Lyons; The Management of a Myomatous Pregnant Uterus, by Dr. W. W. Wathens; Experimental Investigations on Puerperal Sepsis, by Dr. F. Gaertner; The Simultaneous Occurrence of Extra- and Intra-uterine Pregnancy and a Tabulated Record of 62 Cases Collected from 1708-1901, by Dr. E. Gustav Zinke; Cholæmia and Hæmorrhage, by Dr. D. T. Gilliam; Renal Insufficiency in Relation to Women, by Dr. J. T. Jelks; Clinical Considerations Relating to Cancer of the Uterus, by Dr. A. F. Currier; The Medication and Treatment of Uterine Fibroids, by Dr. W. B. Ghase.

SECTION ON GYNÆCOLOGY AND ABDOMINAL SURGERY.—Cancer of the Fundus Uteri, by Dr. J. M. Baldy; Treatment of Prolapse of the Uterus, by Dr. H. T. Byford; Ureteral Implantation into the Intestines—A New

Method with a Bacteriological and Histo-pathological Study of the Kidney, by Dr. Jacob Frank; Intestinal Sutures, All Knots Inside, by Dr. F. G. Connell; The Complications and Degenerations of Fibroid Tumors as Bearing upon the Treatment of these Growths, by Dr. Chas. P. Noble; Septic Peritonitis, by Dr. C. H. Anderson; The Angeiotribe, by Dr. H. P. Newman; Shock in Abdominal Surgery, by Dr. F. B. Turek; Some Points in the Technique of Hysterectomy, by both Infra- and Supra-pubic Methods, by Dr. W. H. Wathen; Cocaine Anæsthesia by Lumbar Puncture in Gynæcology, by Dr. J. Riddle Goffe; Combined or Multiple Surgical Operations at One Séance in Female Patients, by Dr. R. S. Sutton; When and How Should a Ruptured Ectopic Pregnancy be Operated Upon, by Dr. Paul F. Munde; The Author's Flap Operation for Atresia of the Vagina, with Demonstration, by Dr. Geo. H. Noble; Pelvic Suppuration, by Dr. Joseph Price; Water, its Uses Internally in Abdominal Surgery, by Dr. W. H. Humiston; Heptotomy for the Relief of some Conditions Produced by Biliary Obstruction, by Dr. W. E. B. Davis; Gangrenous Hernia and Intestinal Jointing, by Dr. Thomas H. Manley; Surgical Diagnosis of Abdominal Tumors, by Dr. W. H. Earles; The Technics of Appendicectomy *per se* and as Modified by Combination with Lumbar Appendicectomy and Lumbar Exploration of the Gall Bladder and Bile Ducts, by Dr. Geo. M. Edebohls; The Operative Treatment of Carcinoma Uteri, by Dr. E. E. Montgomery; The Pus Factor in Appendicitis, by Dr. Ramon Guitéras; Three Dangerous Operations—Repair of Lacerated Cervix, Rapid Dilatation of Cervix, and Curettement, by Dr. John B. Deavor; On the Desirability of Combined Operations in Pelvic and Abdominal Surgery, by Dr. W. P. Manton.

SECTION ON OPHTHALMOLOGY.—A New Clinometer for Measuring the Torsional Deviation of the Eye and Estimating the Degree of Distortion Produced by Cylindrical Glasses, by Dr. Alex. A. Duane; Carcinoma of the Orbit, by Dr. Shumway; Report of a Case of Removal of the Superior Sympathetic Cervical Ganglion for non-Inflammatory Glaucoma, by Dr. Joseph Mullen; Case of Blindness from Sympathetic Ophthalmitis Complicated with Secondary Glaucoma—Restoration of Vision by Two Iridectomies, One with Extraction of Lens and Iridocystectomy, and Tynell's Operation of Drilling, by Dr. Chas. A. Oliver.

SECTION ON LARYNGOLOGY AND RHINOLOGY.—How to Prevent Stammering, by Dr. G. H. Makuen; The Tonsils as Ports of Entry for Pathogenic Organisms, by Dr. Irving Townsend; Injurious Effects of Forced Breathing upon Voice Speaking and Singing, by Dr. Carl Seiler; A Case of Sympathetic Cough Cured by Removal of Spur from the Nasal Sæptum, by Dr. E. F. Ingalls.

SECTION ON OTOTOLOGY.—Remarks on Sinus Thrombosis, by Dr. T. Y. Sutphen; Symptomatology of Treatment of Sinus Thrombosis, by Dr. J. F. McKernon; A Critical Review of the Literature of Mastoid Disease—Its Complications, by Dr. S. Oppenheimer; A Brief Résumé of Experience with Carbolic Acid in the Treatment of Mastoid Wounds and Chronic Suppuration of Middle Ear, by Dr. Wendell Phillips; Report of Mastoid Cases, by Dr. J. O. W. Reynolds; Some Remarks on Mastoid Operations as Done in England, France, Germany, and America, by Dr. A. Hobbs; Importance of an Incision in the Inferior Posterior Portion of Canal in Acute Attical Diseases, by Dr. J. O. Tansley; Review of Otological Literature for Two Years, by Dr. Wilson; Use of Aqueous Extract of Suprarenal Capsule in Ear Diseases, by

Dr. W. A. Bates; Two Cases of Ligature of the Internal Jugular Vein for Infective Thrombosis of the Sigmoid Sinus, Due to Purulent Otitis Media—One Recovery and One Death, by Dr. Fred L. Jack; Artificial Aids to Hearing, by Dr. Ed. B. Dench; Acute Otitis Media and Acute Mastoiditis in Scarlatina, Measles, and Diphtheria—A Clinic Report of 5,000 Cases, by Dr. A. B. Duel.

SECTION ON MARINE HYGIENE AND QUARANTINE.—Need of a National Health Department, by Dr. Liston H. Montgomery; On the Agency of Parasitic Vermin and other Insect Pests in the Spread of Disease, by Dr. G. Homan; The Necessity for the Organization of Bacteriological Commissions for the Study and Investigation of Quarantinable Diseases under the Formation and Control of the Governing Authorities of the Countries Interested—An Absolute Requirement for the Scientific Management and Betterment of Maritime Hygiene and Quarantine, by Dr. Henry B. Horlbeck.

SECTION ON MENTAL AND NERVOUS DISEASES.—Morphinism and Crime, by Dr. T. D. Crothers; Syphilis and Insanity, by Dr. H. Waldo Coe; Cerebral Neurasthenia—Observations on Diagnosis and Treatment, by Dr. D. R. Brower; Possible Cause of Insanity among Americans in the Orient, by Dr. A. J. Ashmead; Autopsychorrhhythmia or the Repetition Psychoneurosis—An Inquiry into a Condition of Morbid Rhythmic Cerebral Automatism and its Rhythmic Forms of Mental Alienation, by Dr. C. H. Hughes. Subject for general discussion, Interrelation of the Nervous System and Female Genitals in the Neurotic Diseases of Women.

SECTION ON MEDICAL PEDAGOGY.—A Plea for Modern Methods of Teaching in Our Medical Colleges, by Dr. J. W. May; Hospital Service a Prerequisite for a License to Practise Medicine and Surgery, by Dr. G. W. Galvin; Some Observations Respecting the Value of the Present Methods of Medical Education, by Dr. A. P. Clarke; The Association of American Medical Colleges; Some of the Work it Has Accomplished, by Dr. D. S. Reynolds; The Next Educational Revolution—What Shall it Be? by Dr. D. B. Cornell; Remarks on the Method of Treating Mental Diseases, by Dr. Ira Van Gieson.

SECTION ON DENTAL AND BUCCAL SURGERY.—Can Interstitial Gingivitis be Prevented and How? by Dr. M. H. Fletcher; Tuberculosis of the Alveolar Process and Surrounding Tissues and a Few Methods of Differential Diagnosis, by Dr. G. F. Eames; The Gingiva and Pericementum, by Dr. W. E. Walker; Irregularities of the Teeth and their Treatment, by Dr. A. E. Baldwin; Treatment of Interstitial Gingivitis, by Dr. Eugene S. Talbot; a paper, the title of which is to be announced, by Dr. G. V. I. Brown.

SECTION ON GENERAL HYGIENE AND DEMOGRAPHY.—Restrictions on Enteric Fever, by Dr. H. B. Baker; Problem of Infected Well Persons, by Dr. Chas. V. Chapin; papers, with titles to be announced, by Dr. Roger S. Tracy, and by Dr. Alvah H. Doty.

The Medical Society of the State of New York.—The ninety-fifth annual meeting will be held in Albany, on Tuesday, Wednesday, and Thursday, January 29th, 30th, and 31st, under the presidency of Dr. A. M. Phelps. In addition to the president's inaugural address, the programme contains the following titles: Recent Progress in the Treatment of Pneumonia, by Dr. James King Crook; Congenital Dislocation of the Shoulder, with a Report of Cases, by Dr. Daniel W. Marston; Appendicitis and Menstrual Irregularities, by Dr. A. L. Beahan, of Canandaigua; Small Hospitals and their Administra-

tion, by Dr. Louis Nott Lanehart, of Hempstead; The Necessity of Greater Conservatism in the Use of Vasodilators in Certain Cases of Cardiovascular Disease, by Dr. Louis Faugères Bishop; Hernia of the Urinary Bladder, by Dr. William S. Cheesman, of Auburn; The Treatment of Prostatic Hypertrophy, by Dr. Ramon Guitéras; The Medical Society of the State of New York—Its Past and Future, by Dr. Albert Vander Veer, of Albany; What Is Rodent Ulcer? by Dr. John A. Fordyce; Noma of the Genitalia, by Dr. Andrew McFarlane, of Albany; Esophoria, or Latent Squint, by Dr. Francis Balk; Changes in the Crystalline Lens during Accommodation, by Dr. Lucien Howe, of Buffalo; Tuberculosis of the Iris, by Dr. W. F. Mittendorf; Can Interstitial Keratitis be Prevented in the Offspring of Syphilitic Parents? by Dr. Peter A. Callan; The Treatment of Chronic Purulent Otitis Media, by Dr. James F. McKernon; Operations for Deformities Following Pott's Fracture, by Dr. W. O. Plimpton; Indications for Operations upon the Mastoid, by Dr. Wendell C. Phillips; Indications and Limitations of the Vaginal Route of Attack in Pelvic Diseases of Women, by Dr. J. Riddle Goffe; What Complications of Pregnancy, Labor, or the Puerperium Justify Abdominal Section? by Dr. William Warren Potter, of Buffalo; The Treatment of Persistent Suprapubic Fistula Resulting after Ovariectomy, by Dr. Willy Meyer; Results Following the Cure of Chronic Defects of the Vesical Function, by Dr. Eugene Fuller; Ectopic Pregnancy—Primary Rupture—the Opportune Time for Making a Diagnosis, by Dr. George McNaughton, of Brooklyn; An X-ray Study of the Cause of Disability Following Fractures Involving the Elbow Joint, by Dr. Samuel Lloyd; Contributions to Abdominal Surgery, by Dr. James E. Kelly; Loose Cartilage in the Knee Joint, by Dr. P. R. Furbeck, of Gloversville; Pus in the Peritoneal Cavity, by Dr. Robert T. Morris; The Indications for and Limitations of Spinal Cocainization in Surgery, by Dr. George R. Fowler, of Brooklyn; The Results of Nephropexy for Movable Kidney, by Dr. George M. Edebohls; The Relations between Certain Diseases of the Skin and the Menstrual Function, by Dr. L. Duncan Bulkeley; Hysterical Anæsthesia and Analgesia, by Dr. B. C. Loveland, of Syracuse; Deep Breathing as a Curative and Preventive Measure, by Dr. John H. Pryor, of Buffalo; Belladonna versus Scopolia, by Dr. Reynold W. Wilcox; Disinfection within and without the Body in Diphtheria, by Dr. M. A. Veeder, of Lyons; Afterthoughts on Diphtheria, by Dr. I. N. Love; Fatty Degeneration of the Heart, by Dr. Thomas E. Satterthwaite; Recent Experiences with Erythromelalgia, by Dr. Henry L. Elsner, of Syracuse; A Simple and Accurate Method of Substitute Infant Feeding, by Dr. Henry Dwight Chapin; Leprosy in the Hawaiian Islands, by Dr. Charles E. Davis, of Albany; The Tonometer and its Value in Determining Arterial Tension, by Dr. Henry L. K. Shaw, of Albany; Pleuropericardial and Diaphragmatic Adhesions, by Dr. D. H. Goodwillie; Differential Diagnosis in Diseases of the Spinal Cord, by Dr. E. D. Fisher; Masturbational Neuroses, by Dr. William C. Krauss, of Buffalo; Arthritis Deformans, by Dr. Herman Mynter, of Buffalo; Tenosynovitis Calcarea, by Dr. Carl Beck; The Treatment of Puerperal Fever, by Dr. Herman J. Boldt; The Immunizing Effect of "Rag Weed" in Hay Fever, by Dr. H. Holbrook Curtis; Inguinal Hernia, by Dr. B. Merrill Ricketts, of Cincinnati; Gastrojejunostomy in Gastrectasis, by Dr. A. H. Cordier, of Kansas City; The Toxine of the Colon Bacillus, by Dr. Victor C. Vaughan, of Ann Arbor, Mich.; Tetanus Following Clean Operations, by Dr. Joseph W. Bissell; The Advances in State Medicine, by Dr. M. J. Lewi; Aseptic

and Antiseptic Precautions in Dental Surgery, by Dr. J. B. Ransom, of Dannemora; The Treatment of Delirium Tremens by the Intravenous Infusion of Saline Solution, by Dr. James P. Warbasse, of Brooklyn; and A Report of a Case of Brain Tumor—Operation—Improvement, by Dr. William M. Leszynsky and Dr. James H. Glass, of Utica.

The Japanese Red Cross Society.—The *Army and Navy Journal* states that Surgeon-General Van Reypen, U. S. N., has received from Medical Inspector Harmon, on duty at Yokohama, a recent letter to him from Count Sano, president of the Japanese Red Cross Society, which says: "The Japanese Red Cross Society is very active in its ministrations to their own soldiers and sailors returned from the China war, and it is equally kind and attentive to the sick and wounded in the foreign hospitals here. Count Sano is a member of the Imperial Privy Council, and a prominent man in Tokio."

A Baronetcy for the President of the Royal College of Physicians of London.—Among the honors granted for the new year by the Queen of England is a baronetcy for Dr. Church. Sir William Selby Church, Bart., is the president of the Royal College of Physicians of London. Other noted English medical men decorated, are Dr. Thomas Barlow, professor of clinical medicine of University College, who has been made a baronet; Dr. Hugh Adcock, consulting physician-in-chief to the Shah of Persia, who has been made a Companion of the Order of St. Michael and St. George; Sir William Turner, president of the General Medical Council, who has been created a Knight Commander of the Most Honorable Order of the Bath; and Major John Crimmin, V. C., of the Indian Medical Service, now a Companion of the Most Eminent Order of the Indian Empire.

The late Dr. Horace T. Hanks.—At the annual meeting of the Medical Association of the Greater City of New York, held at the New York Academy of Medicine on January 14, 1901, the following report was presented:

The committee appointed by the president, Dr. Weir, at the December meeting of this association, to prepare a suitable minute in regard to the death of Dr. Horace Tracy Hanks, begs leave to report as follows:

"It is with sorrow that we are called upon to report the death of Dr. Horace Tracy Hanks, one of the charter members of our association. Dr. Hanks died of Bright's disease at his home, in this city, on November 18, 1900. He was born in East Randolph, Vermont, on June 27, 1837. He graduated from the Albany Medical College in the class of 1861. After serving in the Union Army as an acting assistant surgeon for two years, he began the practice of medicine in Royalston, Massachusetts, where he remained, however, for a short time only, removing to New York City.

"He held many positions of responsibility, among which were the professorship of the diseases of women in the Post-graduate Medical School and attending surgeon to the Woman's Hospital in the State of New York. He was consulting gynecologist to the Tarrytown, Mount Vernon, and St. Joseph's hospitals. He was a member of the New York Academy of Medicine, the Medical Society of the County of New York, the New York Obstetrical Society, and the American Medical Association, and was a fellow of the American Gynecological Society and of the British Gynecological Society.

(Signed) }
HENRY D. NICOLL, }
CLEMENT CLEVELAND, } Committee."
EDWARD E. TULL, }

New Officers of the Medico-Legal Society.—The annual meeting for the election of officers of the Medico-Legal Society was held recently at the Hotel St. Andrew in this city. About forty members were present, and the following officers were elected: President, Clark Bell; first vice-president, George S. Porter; second vice-president, F. D. Crothers; secretary, H. G. Chapin; corresponding secretary, M. Ellinger; pathologist, F. B. Downes, M. D.; treasurer, Miss Caroline F. Taylor; chemist, Professor Charles H. Doremus; curator, Dr. J. Mount Bleyer; toxicologist, Professor W. B. McVey; librarian, F. L. Hoffman; assistant librarian, F. G. Frost; bacteriologist, B. G. Demoise; microscopist, Dr. E. J. Lederle; legal trustee, Judge A. J. Dittenhoefer; medical trustee, Dr. G. S. Heft; legal counselor, F. E. Crane; medical counselor, Dr. G. Chaffe; permanent commission, L. A. Emory (legal) and George L. Porter (medical). The chief paper of the evening was that read by Dr. Albert Bach on The Rehabilitation of the Medical Expert. At the conclusion of Dr. Bach's paper discussion on the subject was invited. Judge Daly, of Brooklyn, condemned the custom of large corporations retaining physicians as experts at a regular yearly salary, and said that such evidence should never be admitted in any court of justice. Mr. Henry Wollman said that he had noticed that in the testimony given in the Molineux case no two experts gave the same reason for arriving at a conclusion. Mr. Tucker said he thought that what was really needed was not better doctors, but better men. A memorial on the death of the late Cushman K. Davis was read by Mr. Bell, the president, after which the meeting adjourned.

The Sale of Absinthe Prohibited in France.—The Chamber of Deputies has adopted a resolution calling upon the government to prohibit the manufacture and sale of all alcoholic liquors pronounced dangerous by the Academy of Medicine. The resolution was aimed at absinthe, the consumption of which has nearly doubled in France since 1894, and now stands at 10,000,000 litres annually.

Medicine and Medical Journalism in Greece.—The *British Medical Journal* for January 5th says: "Dr. Foustanos gives, in a recent number of *La Grèce médicale*, a history of medical journalism in Greece, which virtually begins with the existence of that country as an independent State in 1830. Before that time medical science could hardly be said to exist in modern Greece. If now and then a scientific work was written in Greek, it was printed at great expense in Italy, mostly at Venice. After the emancipation of Greece, Greek physicians began to return to their country from Italy and other parts of Europe, and a new era in the scientific life of the nation began. A medical society was founded at Athens in 1836, and began to issue the first Greek medical review, which took its name from Asklepios, the god of medicine; its life was short, for it died in 1839. A *New Asklepios* was started in 1842 by G. Prinaris, and lived till 1847. Yet a third incarnation of *Asklepios* appeared in 1856. There have been at different times three journals bearing the name of Hippocrates, and two that of Galen, besides a *Medical Bee* and some dozen other variously named journals. These all have long had to be spoken of in the aorist tense. At the present time there are only two medical journals in Greece—*Ἱατρικὴ Πρόοδος* (*Medical Progress*), published in Greek, and *La Grèce médicale* in French. The editor of both these journals is Dr. J. Foustanos, of Syria."

Original Communications.

A PRELIMINARY COMMUNICATION,
WITH
PROJECTION-DRAWINGS, ILLUSTRATING
THE TOPOGRAPHY OF THE PARACÆLES
(LATERAL VENTRICLES)
IN THEIR RELATIONS TO THE SURFACE
OF THE CEREBRUM AND THE
CRANIUM.*

BY EDWARD A. SPITZKA,
NEW YORK,

STUDENT OF MEDICINE, COLLEGE OF PHYSICIANS AND SURGEONS.

TAPPING, draining, and injecting the paracæles (as the lateral ventricles are to be designated) have become recognized surgical procedures, both for diagnostic and for therapeutic purposes. The mode of procedure, however, is yet far from technical perfection and would be more often resorted to if the surgical risks and topographical uncertainty were removed.

Tapping of the paracæles was first proposed by Wernicke (1) in 1881, and later by Zenner (2) in 1886. W. W. Keen (3), of Philadelphia, in 1888, first formulated rules and a technique for puncturing the brain with the purpose of entering the cavity, and he has pointed out that the operation is justifiable, that it can be done, safely, and that it may be the means of saving life. A most important suggestion has recently been made, namely, the treatment of tetanus by the injection of anti-tetanic serum, either intracerebrally or directly into the paracæles. Without encroaching on a theme which, not being within my province, it is not my purpose to discuss, I may be allowed to assume as accepted that the operation has a future. Lewandowsky (4) and others have shown, in experimenting with drugs which were thrown into the cerebrospinal fluid, that these substances penetrated the nerve-substance through the lymph-channels, and without the intervention of the blood-vessels.

That the operating surgeon may feel reasonably confident of striking the paracæles presupposes accurate anatomical knowledge on his part; and I may say that nowhere in the human body does Holmes's aphorism apply so pointedly: "Let the eye go before the hand, and the mind before the eye." In the conception of the contour and depth of these hidden cavities the surgeon must rely chiefly upon his imagination and upon the most accurate knowledge of the correlations of the parts. Correct anatomical plates showing the relative topography may be of some service in the execution of such procedures. As in some other fields of operative surgery, reference plates which are both reliable and clear are a desideratum. The

otherwise excellent plates of Fraser (5) lack the clearness so essential for busy practical men. Aside from these, I can find no correct representations of the cerebral and cranial relations of the paracæles. A search of the literature made by the writer reveals only three attempts essaying to depict such topography:

1. In France, Chipault (6), in an almost miniature reproduction from Poirier (7), shows a lateral view of the skull with an incorrect outline of the paracæle.

2. In England, Wilson (8), in 1894, published three projection-drawings of the brain which were primarily intended to show the relations of the internal capsule to the gyres of the surface, but in addition he outlined the paracæles. These drawings, however, fail to present a true contour of these cavities; in fact, it is evident from his "dorsal view" that he ignores the existence of an epithelial floor and wall of the paracæles, and, further, these structures are not brought into correlation with the cranium.

3. Quain (9) presents a figure which, not purporting to be aught but a schematic outline, is unavailable for surgical use.

The propositions presented herewith are offered as preliminary only. They are based upon dissections of two adult heads. It is the writer's purpose to utilize as large a number of heads as possible, of children as well as adults, and of different sex and race. A description of the two heads follows:

HEAD No. 1.

(See Figures 1, 2 and 3.)

J. L., native of United States, white, male; aged fifty-eight years; died March 30, 1900, of phthisis; height, 175 centimetres (68 $\frac{3}{4}$ inches).

Dimensions of the Skull.

Maximum anteroposterior diameter... 18.3 centimetres
Maximum lateral diameter..... 15.2 centimetres
(Cephalic index, 83°.)
Minimum frontal diameter..... 10 centimetres
Maximum circumference (21 $\frac{3}{4}$ inches) 55.25 centimetres

HEAD No. 2.

(See Figures 4, 5 and 6.)

J. B., native of the United States (doubtless of Hibernian descent), white, male; aged sixty-nine years; died March 27th, of old age; height, 160 centimetres (63 inches).

Dimensions of the Skull.

Maximum anteroposterior diameter... 18.8 centimetres
Maximum lateral diameter..... 14 centimetres
(Cephalic index, 74.46°.)
Minimum frontal diameter..... 10.1 centimetres
Maximum circumference (20 $\frac{3}{4}$ inches). 53 centimetres

*Read before the Association of American Anatomists, in Baltimore, December 28, 1900. The writer is indebted to Professor Huntington and Dr. Gallaudet, of the College of Physicians and Surgeons, Columbia University, for the anatomical material employed in the preparation of this report.

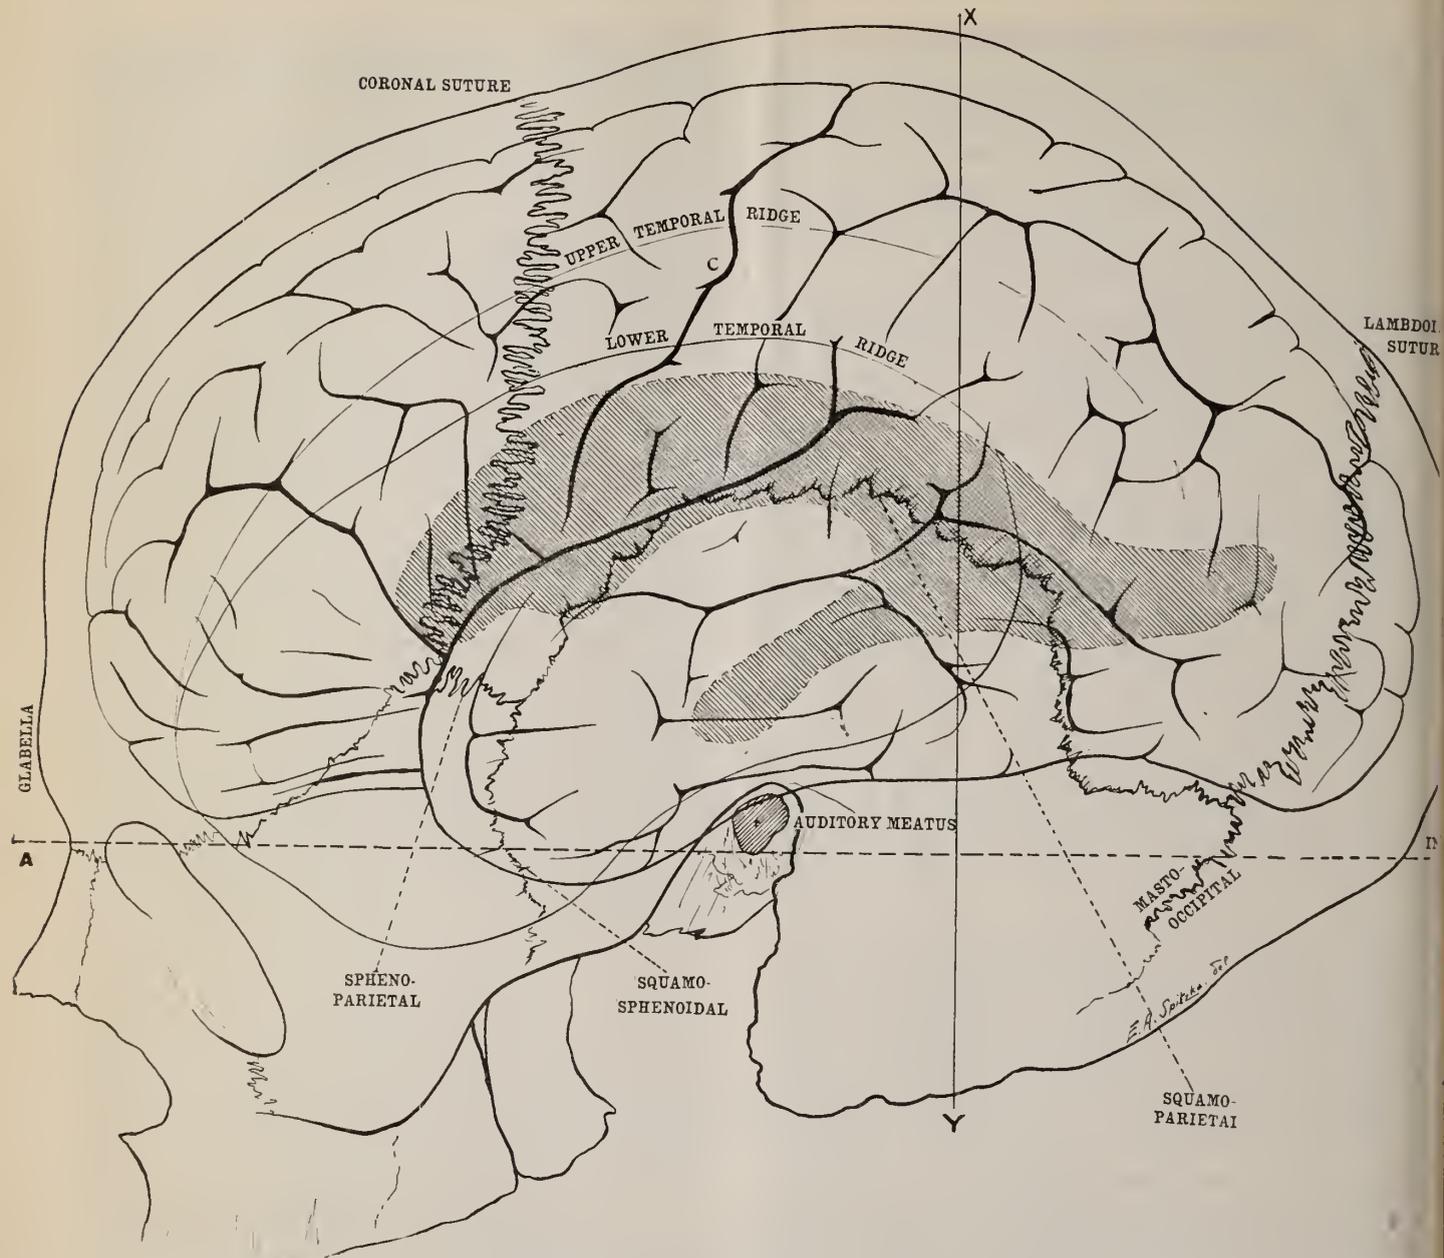

FIG. 1.—Lateral view of Head No. 1. The paracæle is shaded. C is the central fissure. Line AB passes through the inion and the external angular process of the frontal. Line XY indicates line of section illustrated in Fig. 3.

In each case, the head was removed from the cadaver after the usual sodium arsenite and red starch arterial injection. The scalp and superficial soft parts were dissected off to facilitate impregnation by the hardening fluid, the skull was trephined, and the paracæles were injected, following Keen's directions, with 60 cubic centimetres of the 10-per-cent solution of formaldehyde. This quantity, judging from my experience, seems to be about as much as the coelian cavities may hold, from the fact that only a few drops escaped from the metapore and the myelocæle, where the myelon (spinal cord) was severed. The outline of the cavities on section sustained this view. The entire head was then immersed in formaldehyde solution of 5-per-cent. strength, care being taken to allow the fluid to gain free access to the entire brain surface through incisions in the dura at the site of the trephine

openings. After one month's hardening the skull was thoroughly cleansed, and the drawings and measurements were made. The writer's purpose had been to decalcify the skull and make the sections through brain and skull in their natural relations. This was attempted on the second head, but, unfortunately, in that particular case the skull was so thick in parts that the method was temporarily abandoned, but is intended to be resumed. The skull was opened and the brain, which had hardened well in both cases, was carefully removed. The brain, with its fissures, gyres, and blood-vessels, was then measured and drawn, special attention being paid to their relations with the configurations of the cranium. It was next cut into sections, one fourth of an inch in thickness, in a sectioning-box contrived by the writer, the cuts being made coronally and perpendicular to the plane passing

through the external angular processes of the frontal and theinion. With a series of tracings made directly from the sections, and with the aid of simple draughtsman's appliances, the outlines of the paraceles were projected upon the surface of the cerebrum as well as the cranium, both laterally and dorsally. The accompanying figures show these relations in a way which may prove of some service to the practical surgeon. Such topographical plates cannot be expected to entirely set aside the value of measurements; indeed, a judicious combination of measurements with these figures is desirable. It is doubtful whether any system of mathematical measurements can be devised that will apply with mathematical accuracy to all heads. Cunningham, Horsley, Merkel, and others have shown that the craniocerebral relations vary with age, sex, race, pressure distortion, and cephalic index, and

that the practical application of topographical procedures according to systems involving arbitrary lines, such as verticals raised from a base-line, and even measurements, are often misleading, and thus become sources of error and disastrous surgery.

The arguments of Hare, Chipault, and Merkel led me to adopt the plane, indicated by the line AB in Fig. 1, passing through the external angular frontal processes and theinion, as being the most constant plane in its relations to the cerebrum. The popular "Reid's base-line" has been shown by Merkel to be untrustworthy, because too variable, and it is therefore unavailable for these researches.

As in all experiments in craniocerebral topography, the following sources of uncertainty must be borne in mind:

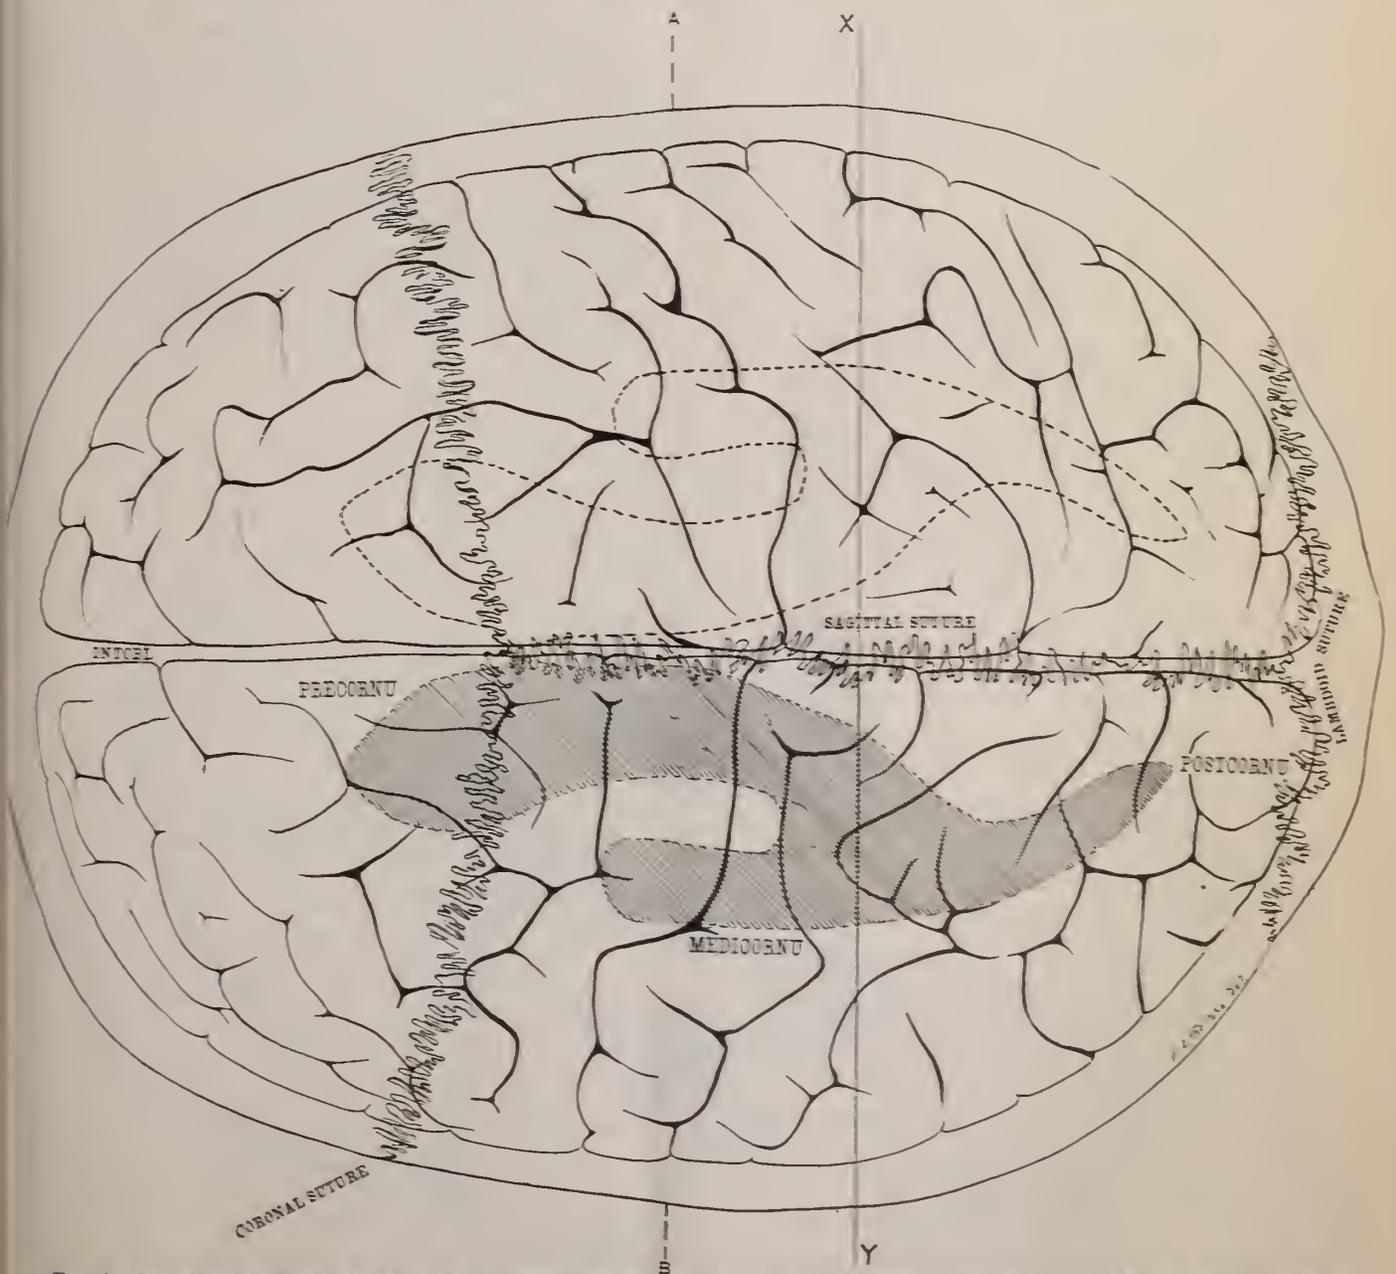

FIG. 2.—Dorsal view of Head No. 1. Line AB passes through the centres of the auditory meatuses. Line XY as in Fig. 1. Left paracel is shaded, outlined on the right side by a broken line.

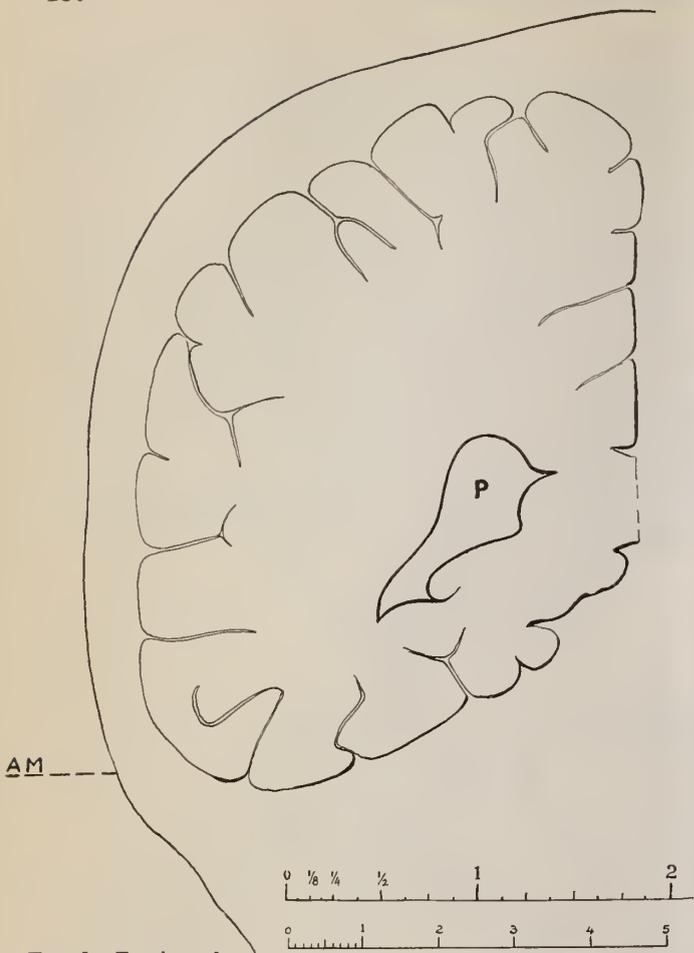

FIG. 3.—Tracing of the section indicated in Figs. 1 and 2 by the line XY. P marks the paracæle. AM is at the level of the auditory meatus.

1. Variability in the relations of the fissures and gyres to the sutures and other cranial landmarks.
2. The difference between the surface area of the brain and of the skull; this causes a difference in the exact correspondence of lines drawn upon them.
3. The intrinsic differences in the fissural and gyal patterns of different individuals.

To what extent these variations are to be recognized can only be determined by the examination of a large number of heads before I venture to offer any definite formulations. So far as the variations of the paracæles themselves are concerned, they are mainly these:

1. Variations in the greater or lesser cephalic extension of the præcornu and medicornu and the caudal extension of the postcornu, the third being particularly inconstant.
2. Variations in the contour of the curve of any part of the paracæle, notably in the medicornu and postcornu.
3. The existence of lacunæ or loculi of the cavity formed by the intervention of sæpta of pathological or congenital origin. Anomalies of this kind are most frequent, it seems, in the postcornu.

The reader will recognize the normal outline of the paracæles, as they have been made familiar to us by Welcker's plaster casts, in head No. 1, and in the left half of No. 2 (Figs. 1, 2, 4, and 6). The contour of the right paracæle in the second head is abnormal to a remarkable

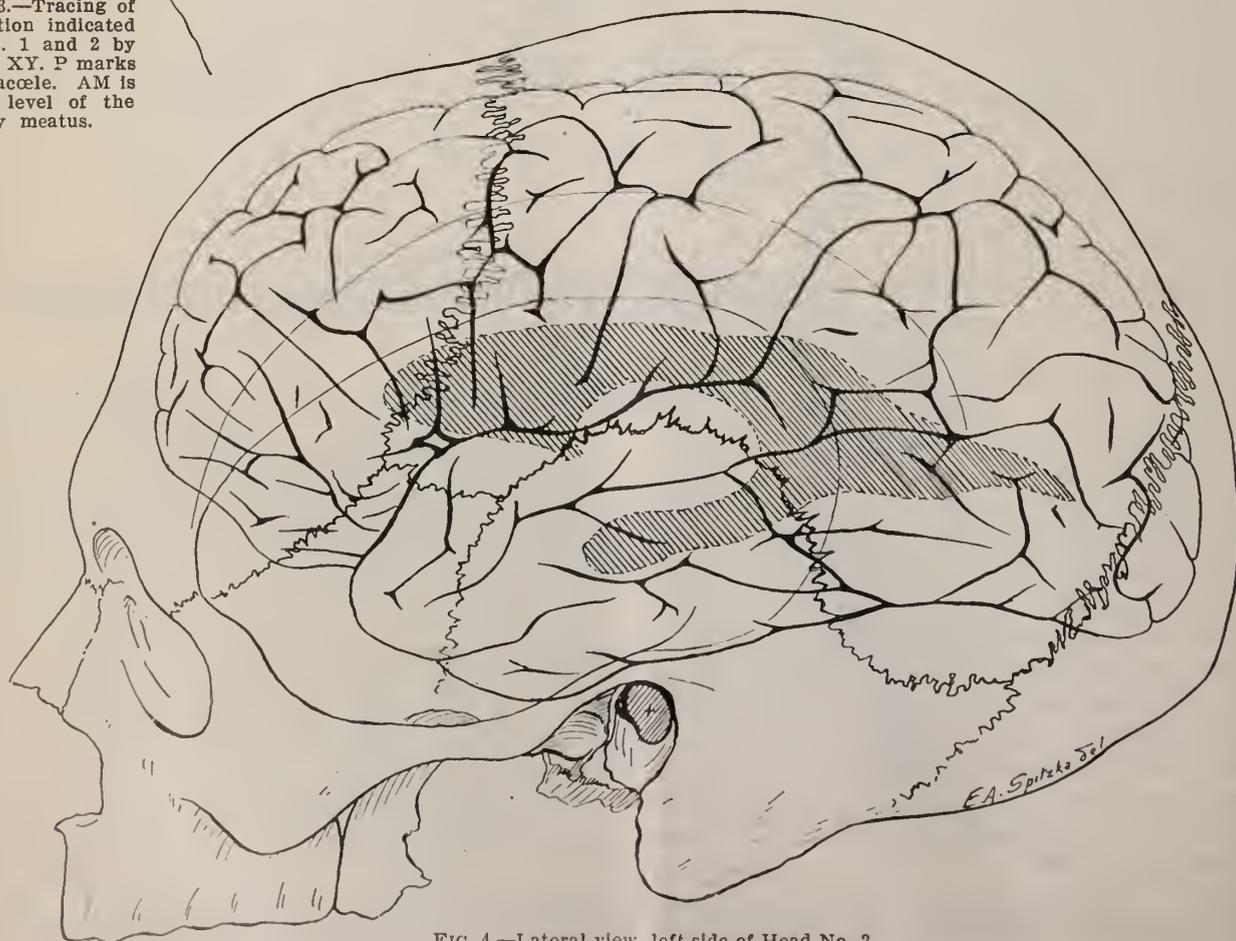

FIG. 4.—Lateral view, left side of Head No. 2.

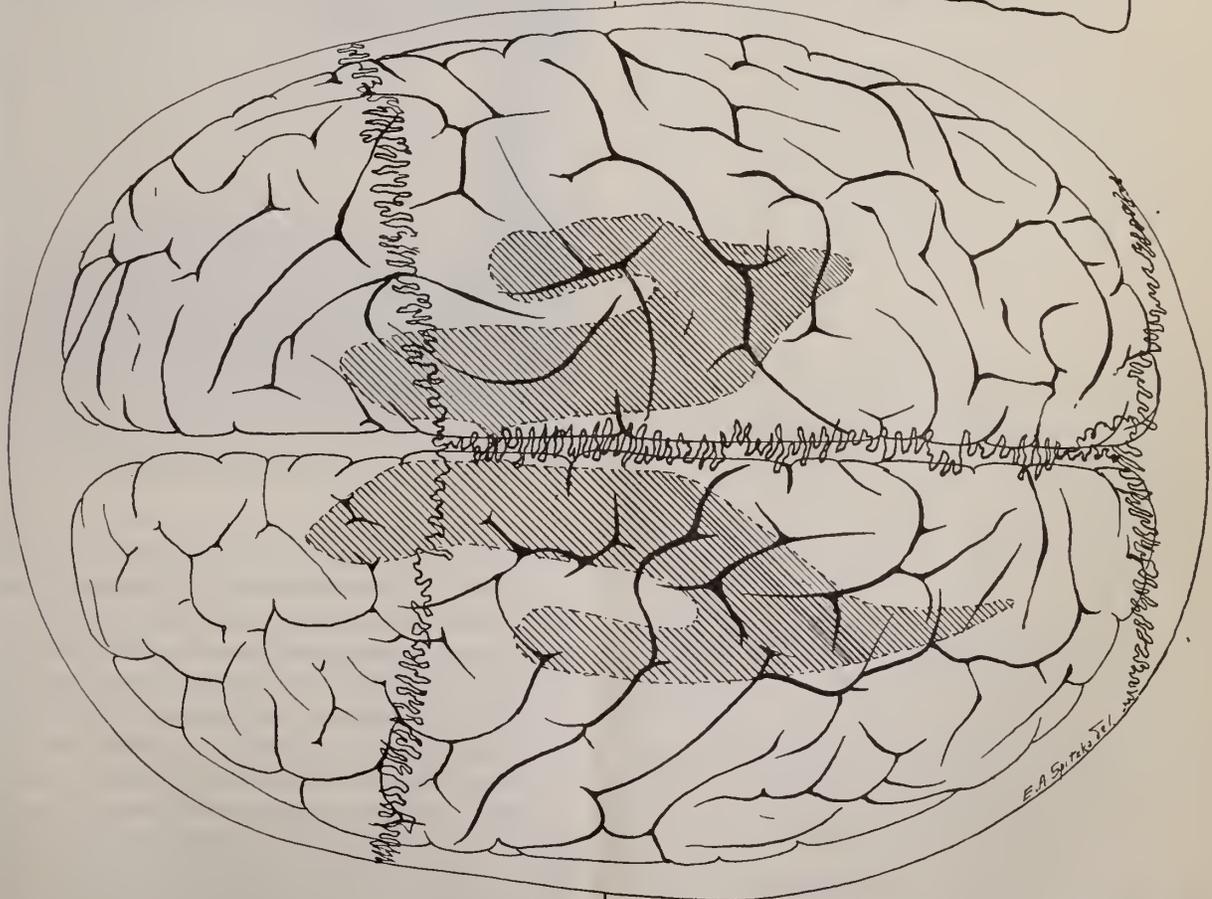

FIG. 6.—Dorsal view, Head No. 2. Line AB passes through centre of external auditory meatus.

B

degree. The postcornu is over an inch shorter than in the left half, the medicornu is somewhat longer, and the præcornu is slightly shorter. The "trigonum ventriculi" is slightly displaced cephalad. A careful examination failed to reveal any lacuna that might have been cut off from the postcornu. It were interesting to determine the frequency and range of these and like variations, for in the absence of external indications of such asymmetry, the success of an operation in such a case as this would, to say the least, be problematical.

For the purpose of effecting an entrance into the cavity, the safest road would seem to be the one which is directed into the "trigonum." Keen (10) prefers to reach the cavity at the beginning or in the course of the medicornu. The *trigonum* is the roomiest part of the paracœle, and its dimensions permit of the choice of any of the several routes of approach, according to the judgment of the operator. It is the least variable portion of the paracœle, so far as its dimensions and topography are concerned, and it is never lacunated, or at least has never been so reported that I am aware of. The size of this part may be estimated in Fig. 3, which is a tracing of the section at the line XY in Figs. 1 and 2. The line AM marks the level of the auditory meatus. The variability of this level probably invalidates most systems of measurement concerning paracelian relations. As stated before, it is only by means of averages based upon a large number of cases that we can obtain any reliable guides for an operation which, it seems, is acknowledged to have a fruitful future.

In the accompanying figures the writer has attempted to represent the cerebral and cranial relations of the paracœles as faithfully as the available material permitted. For present purposes it has been deemed best to omit the cerebral and dural blood-vessels, as well as the representations of cortical centres. These features may be supplied in a final report of the completed researches.

A CASE OF ARSENICAL DERMATITIS.*

By A. H. OHMANN-DUMESNIL,

ST. LOUIS, MO.

WHILE cases of dermatitis medicamentosa are not rare by any means, each one possesses a certain amount of interest, either on account of the poisoning agent, its dose or manner of ingestion, or on account of the peculiar changes that manifest themselves in the skin. Added to this are the varying degrees of susceptibility manifested

by individuals and the various subjective symptoms of which they complain, as well as the objective signs which they present to the observer. The eruptions presented in arsenical dermatitis are numerous, but their localizations vary in a great measure. Of course, it is not my purpose here to present a complete, or even a partial, account of these, for they may be easily found in textbooks. What I purpose doing is to relate a case and add thereto a few remarks bearing upon it.

CASE.—S. K., a single woman, twenty-six years of age, of Polish origin, has always enjoyed the best of health. Being an orphan and without means, she en-

*Read before the St. Louis District Medical Society, December 19, 1900.

tered domestic service. In the course of time a man, whose name she refused to disclose, paid his attentions to her. This led to further intimacy and culminated in her pregnancy. She was safely delivered of a living child. On her insisting upon marriage to her lover, he refused and left the city. Racked by remorse and despondency, the girl saw but one escape from her troubles—suicide. In order to compass this end she retired to her bedroom and swallowed a heaping teaspoonful of "rough on rats." The pain produced was so excruciating that her cries drew the attention of the lady of the house. She immediately called in a policeman, who had the girl conveyed to the City Dispensary, where her stomach was washed out. Thence she was brought to the City Hospital and subjected to another washing out of the stomach. By this time she was nearly exhausted and was placed in bed, some diffusible stimulants being administered. When able to speak, she complained of intense burning pain in the mouth, stomach, and intestines.

When I saw her, two days later, she showed a decided eruption. On the face the principal lesions were vesicles, with some pustules. A glance at the annexed figure will give a general idea of the condition which existed. The lips and nose were swollen. On the left side of the forehead there were discrete vesicles and a few small pustules. At the root of the nose there was a pustule emptied of its contents. On either side of the nose were discrete vesicles, while the upper lip showed a confluent eruption of the same lesions. The lower lip presented the same lesions and also the chin. The vermilion of the lips did not present a single lesion, but was hot and dry.

Upon examining the woman, no other eruption was found, except on the buttocks. The right one had a patch of confluent vesicles of the size of a silver dollar. Here and there a small discrete vesicle could be seen. On the left buttock, which was the one on which she habitually slept, a patch of confluent vesicles existed. It extended forward and implicated partly the labium majus. This latter was much swollen and somewhat edematous.

So far as subjective symptoms were concerned, the patient complained of a burning sensation and of some itching, more particularly of the buttocks. Here, a number of vesicles, torn open by scratching, could be observed. She also scratched one open at the lower lip, and the blood which followed her finger as she rubbed her chin with it may be seen represented in the figure. She was intensely nervous, almost to the point of hysteria, and restless at night. She attempted to jump out of a window of the hospital and had to be restrained, this state of her nerves only serving to aggravate the eruption. No new crops appeared, however, and she made an uneventful recovery.

The interesting features in connection with this case are, in the first place, the fact that the cause of the eruption was a large dose of arsenic taken with suicidal intent. In the descriptions of arsenical dermatitis that have been published, as well as in the articles relating to it, we note that the arsenic has usually been taken continuously and in rather small doses. The patients have been either habitual arsenic-eaters or have taken the drug under the directions of physicians. No mention is made of the eruption following a large and poisonous dose in the classic work of Morrow on *Drug Eruptions*. This is probably due to the fact that, in cases of attempt-

ed suicide, one of two results follow: the subject dies or the stomach is so rapidly and completely emptied that there is no time afforded for the absorption of the arsenic and consequent non-fatal intoxication leading to a dermatitis. Another interesting point is that in connection with the localization of the eruption. In cases of arsenical dermatitis, the upper or lower limbs, or both, are liable to be affected and the region of the mouth is frequently the site of an eruption. The back is also not infrequently attacked. Again, a false herpes zoster follows the use of Fowler's solution, as I have had occasion to observe. But to see the patches of eruption limited to the face and buttocks is a rather unusual occurrence in my personal or reading experience.

It is most probable that the marked nervous excitement in the case I have described not only had some considerable influence in exhausting the patient, but also contributed to making the affected areas large and the individual lesions of greater size than those usually observed. There is no doubt in my mind that this was also a cause for the predominance of vesicles and the comparatively sparse number of pustules.

I offer this short contribution to the subject of arsenical dermatitis in the hope that it may elicit others observed in patients who have ingested lethal doses of arsenic and yet have escaped death.

ON THE STERILIZATION OF MILK; ITS ADVANTAGES AND LIMITATIONS.*

By A. D. BLACKADER, B. A., M. D., M. R. C. S. Eng.,

MONTREAL,

PROFESSOR OF PHARMACOLOGY AND THERAPEUTICS AND LECTURER ON DISEASES OF CHILDREN, MCGILL UNIVERSITY.

IN the infant, digestion appears to be in great part accomplished in the small intestine. There is no long delay in the stomach with prolonged exposure to an acid digestive medium as in the adult, but the milk, after an imperfect curdling, is quickly passed on to the duodenum. For this reason gastric digestion, the safeguard in older children and in adults against the entrance of disturbing micro-organisms into the alimentary tract, in infants affords but a feeble barrier. It is therefore conceded by all that one of the more important conditions in an infant's food is that it be perfectly sterile. The necessity for this is all the greater should the infant's food be more difficult of digestion, or involve a longer time in its digestion, than the natural aliment of the child.

Commercial cow's milk, acknowledged as our great substitute for maternal milk, is never absolutely sterile. In respect to the character and number of the micro-organisms it may contain, its condition is very variable. If carefully obtained under good hygienic conditions, filtered, aerated, and cooled rapidly, and afterward kept without much agitation at a temperature below 10° C.,

*Read before the New York Academy of Medicine, October 18, 1900.

it will contain comparatively few bacteria. But if any of these conditions be unfulfilled, milk will be found to be contaminated by micro-organisms, the variety and number of which will vary in proportion as any of these several conditions have been departed from.

Again, milk obtained under unhygienic conditions, and of which the temperature has been allowed to rise as high or higher than 16° C. for any prolonged period, differs from milk obtained with hygienic precautions and kept at a continuously low temperature, not only in containing numberless bacteria, but also in containing spores and toxins; an important fact, in that we cannot destroy either spores or toxins (using the term toxins in its broad sense) without destroying the quality of the milk as a food.

The number of the different species of bacteria which may be present in milk is very great. Professor Conn (*Annual Report of the Storrs Agricultural Experiment Station, 1899*), writing upon the bacteriology of milk, gives a list of some 200 different species which he has isolated and grown during the course of the past few years. The majority of these, it is true, have been met with seldom, but many are very common. Of only the few can it be said that we have any definite notion of their action when introduced into the alimentary tract of the infant. Several forms are known to produce changes in the milk of a more or less deleterious character; others have distinctly pathogenic or putrefactive properties. To the pathogenic forms, it is unnecessary to, in this assembly, more than simply refer. The occasional presence in milk of the tubercle bacillus, the typhoid bacillus, and diphtheria bacillus, of the germs of scarlet fever and of the various forms of streptococci, is well recognized by all of you as a possible source of danger to your patients.

In reference to those forms which produce deleterious changes in the milk itself, I would quote the statements of H. L. Russell (*Twelfth Annual Report of the Agricultural Experiment Station, University of Wisconsin*), who says that he has isolated and studied fifteen forms which were frequently present; six of which were almost invariably present. Of these fifteen, he found that three produced lactic acid changes; seven produced no recognizable change in the milk; while five, owing to the rennet ferment elaborated by them, produced in a few days a slow coagulation of the casein which was subsequently dissolved by a second tryptic enzyme.

In ordinary milk it is to be noted that while the majority of the individual micro-organisms present belong to the lactic-acid producing class, there are a number of forms which produce little or no acid change in the milk. Russell considers that the great majority of these gain access to the milk during milking, and are in great part derived from the excreta of the cow and stable filth. These extraneous species are either present in the form of spores, or in the form of bacteria apt to develop spores, and are thus liable to persist in sterilized milk. Among these forms Russell mentions the *Bacillus mesentericus*

vulgatus, the common potato bacillus, as having been frequently isolated by him.

In an infant's food, with our present knowledge, all forms of bacteria are undesirable; many are poisonous. How shall we get rid of them? Bacteriologists have told us that almost all forms (the exceptions being forms not likely to appear in milk and cause trouble) are killed by raising the milk to a temperature of from 65° to 70° C. and maintaining it at this point for twenty minutes. When spores are developing, or have developed, however, this temperature will not destroy them, but neither are they killed by exposure to 100° C.

In the very admirable paper already referred to, Russell states that milk pasteurized at 70° C. contains so few bacteria that it may be said to be practically sterile! In 40 per cent. of samples he examined, the number of bacteria to the cubic centimetre after pasteurization at this temperature was less than 1,000. Cream, however, proved a more resistant medium, for in only 10 per cent. of the samples were the bacteria present in such small numbers. As the result of his experiments he concludes that an exposure of milk to a temperature of 70° C. for fifteen minutes, kills 99.83 per cent. of all the micro-organisms in full milk and 99.7 per cent. of the micro-organisms present in cream. The small percentage that remain represent the relative number of organisms that exist in a spore-bearing or latent stage and therefore are not killed by the heat used to effect the sterilization. This percentage, however, is subject to variation. If careless methods of milking prevail, and much foreign matter, such as dirt and particles of excreta, be allowed to gain access to the milk, the number of spores will be much increased and the percentage of bacteria remaining after pasteurization will be much larger. For a similar reason, namely, the development of spores, the older the milk the less successful is its pasteurization; a fact first observed by noting that the milk and cream pasteurized on a Monday, failed to keep as long as that prepared on other days in the week; a failure attributable to the milk pasteurized on that day being older by twenty-four or forty-eight hours than that used on other days.

From these carefully conducted experiments of Russell, we feel assured that pasteurization at 70° C. destroys all forms liable to produce extensive and rapid change in the composition of the milk. All the pathogenic and putrefactive germs are destroyed, as well as all the lactic-acid producing bacteria. And if milk thus pasteurized be immediately placed on ice, or kept at a temperature only slightly raised above 0° C., it will remain sweet and maintain its freedom for many days from bacteria.

Frceman, as the result of his experiments, tells us that a plate planted from milk thus pasteurized and kept at the temperature of the laboratory, usually shows no growth in twenty-four hours. If, however, a cool temperature be not maintained in such milk, bacteria may develop and fermentations other than the lactic acid fer-

mentation may take place, producing changes in the milk, in some cases with difficulty recognized, but which are liable to produce grave disturbances in the intestinal tract of the infant. The same, however, may also be said of milk sterilized at 100° C.

If milk subjected to a temperature of 70° C. is practically free from bacteria, is there any advantage in raising the milk to a higher temperature approaching or even quite up to that of the boiling point? One advantage there may be, that in careless or inexperienced hands the sterilization at 70° C. may be incomplete; but this appears to me the only one, and I think there are many disadvantages.

Russell in his report for this year has, however, gone still further. Finding that in the pasteurization of milk at 70° C. the milk acquires a more or less scalded taste, and undoubtedly undergoes some chemical change, he tested the results obtained by pasteurization at still lower temperatures, and found that on exposure of the milk to a temperature of 60° C. (140° F.) for ten to fifteen minutes, from 98 to 99 per cent. of the bacteria were killed; such pathogenic forms as the cholera spirillum and the diphtheria and typhoid bacillus cannot withstand his temperature, while the lactic-acid producing species or the most part readily succumb. There appeared to be some doubt, however, whether the destruction of the tubercle bacillus was insured by this temperature. De Man, working under Foster, on cheesy matter obtained from the udder of the cow, found that it required one hour at 140° F. and fifteen minutes at 155° F. to destroy his bacillus. On the basis of this work, the latter temperature (155° F.) has until recently been regarded as the lowest that can be employed with safety for the sterilization of milk.

Theobald Smith, however, after many carefully conducted experiments (*Journal of Experimental Medicine*, Vol. iv, 1899, p. 217) has found that the tubercle bacillus, derived from bovine sources, is invariably killed in from fifteen to twenty minutes at a temperature of 60° C. Even after ten minutes' exposure the bacilli were for the most part dead.

Russell applied the results obtained by Smith to further experiments on milk, and found that when he heated tuberculous milk in a test tube to a temperature of 60° C. a pellicle formed on the surface of the milk consisting of fat globules, and coagulated proteids, which protects the tubercle bacilli to such an extent that not infrequently an exposure in open vessels to this temperature for even an hour did not entirely destroy the germs. If, however, this pellicle as it forms, is broken up by stirring or agitation of the vessel, or if the sterilization is conducted in closed vessels, complete destruction of the bacillus quickly takes place at this temperature. Russell therefore very justly concludes that, as pasteurization at 60° C. kills from 98 to 99.8 per cent. of all the bacteria present in milk, including all pathogenic and putrefactive forms, a higher temperature is not desirable, if the slight increase in the

efficiency of the sterilization is to be gained at the expense of other desirable qualities.

Milk raised to a temperature of 100° C. is markedly altered, both in taste and smell. Chemists inform us that definite chemical changes and modifications have occurred. The lactalbumin and globulin are to some extent coagulated, the lecithin, the nuclein, and the caseinogen are altered; the lactose is partially changed and the organic phosphorus is converted into an inorganic phosphate, which is probably without action in the system.

It would also appear that its digestibility by these changes is more or less interfered with, for, notwithstanding the general statement made by some writers that milk sterilized at 212° F. has appeared to be as digestible as milk pasteurized or unpasteurized, there is a very prevalent opinion among physicians to the contrary.

Among the more recent additions to our knowledge on the subject I would quote the statements of Wroblewski (*Oesterrischer Chemiker-Zeitung*, 1898, No. 1), who points out that certain of the calcium salts, which in normal milk are in a soluble state, are made to enter into insoluble combinations by a high temperature. The part played by calcium salts in connection with those bodies, the ferments and their products, whose presence is a special feature of organic fluids, is being more and more fully recognized. As Duclaux (*Traité de microbiologie*, tome ii, 1899) has pointed out recently, ferments of many kinds are only effective in the presence of minute quantities of calcium magnesium or other mineral, the mineral varying with the special form of fermentation.

For the coagulation of blood, calcium must be present, and for the coagulation of milk in the stomach, calcium in a more or less free form must also be present. If the calcium salts in the stomach through heating undergo alteration so that they are rendered insoluble, then the coagulation of the caseinogen will be to that extent arrested or delayed. In corroboration of this it is found that outside of the body boiled milk undergoes coagulation by rennet only with much difficulty. Inasmuch as this primary coagulation in the stomach appears to be necessary for the normal digestion and absorption of milk into the system, it is certainly questionable whether boiled milk as a rule can be absorbed and assimilated as readily as milk which has not been brought to a temperature sufficient to change the condition of its calcium salts.

On the other hand, it is to be noted that this action may sometimes be of distinct advantage in those conditions of the infant's stomach where rennet action, either directly, or indirectly owing to the presence of fermenting bacteria, is so intense as to lead to the development of firm curds. Of the exact influence of this change in the milk on its digestibility in an infant's stomach, however, we must speak with hesitation. It is possible that the absorption of milk can occur without this preliminary curdling, but even if this be true, it is improbable that

the absorption is as rapid and complete as in the case of unaltered milk.*

Another important change which is said to take place in all milk heated over 60° C. is the destruction of probably existing ferment-like bodies. The recent observations of Hericourt and Riehet upon the good effects of raw meat juice in the treatment of tuberculous cases, and yet other observations of recent date, would appear to indicate that natural fluids unacted upon by heat, have certain properties which are absent from the same fluids after exposure to heat, and it is probable that unheated milk contains ferment-like bodies which, when absorbed, are of distinct value to the economy.

This probability that such ferment-like bodies are present in fresh milk has been strengthened by the investigations of Babcock and Russell (*Fourteenth Annual Report of the Wisconsin Experimental Station*), who found that milk obtained in a condition of perfect sterility undergoes a self-digestion owing to the presence of a trypsin readily destroyed by heat.

There are also observations pointing to the fact that immunity to disease may be conveyed through the mother's milk, and it is a matter of general knowledge that these immunity-conferring substances are destroyed by a heat of 60° C. or over. It may be that the absence of such substances in milk sterilized at high temperature, may render children fed exclusively on such a diet more liable than others to certain infections, leading to disturbances in general nutrition.

In this connection I would also call attention to an explanation suggested by Dr. Corlette (*British Medical Journal*, September 1, 1900, p. 573) for the induction of scorbutus in the infant by a dietary of sterilized milk. Physiologists tell us that citric acid is a normal constituent of both human and cow's milk to the extent of about 1 gramme in every litre. Göldner (*Landw. Versuchs. Stat.*, xxxv) states that it is present in greatest amount as a calcium salt, and to a small extent only as a potassium and magnesium salt; and Vaudin (*Jour. of Pharmacology*, xxx, 1894, p. 464) states that the calcium phosphate in milk is held in solution by the influence of these citrates. Calcium citrate, the most important, is comparatively insoluble in water, is much less soluble in hot than in cold water; it is also readily changed by heating into a still more insoluble form. It can readily be imagined, interpreting these facts in the light of Bunge's and Wroblewski's experiments, that in many cases the sterilization of milk at a temperature of 100° C. by alteration and perhaps precipitation of the citric salts gives rise to a deficiency in this very important ingredient of the infant's food.

*Bunge quotes experiments showing that a mixture of the fats, sugars and proteids of milk, washed free of its salts, but to which salts are again artificially added, is incapable of supporting life in mice, which thrive on an unaltered milk—a fact which he thinks is attributable to this dissolution of the combination between the salts and the proteids interfering with the due assimilation of both. This assertion, however, has not yet been verified by other observers.

Milk, moreover, that has been pasteurized or sterilized cannot be kept long without undergoing changes of a more or less deleterious character. Russell, as I have already stated, recognizes the presence in pasteurized milk of bacteria which secrete rennet and subsequently a tryptic ferment. Lübbert (*Zeit. f. Hygiene*, Bd. xxi, p. 450), of Breslau, also states that among the most frequent of the spore-bearing forms found in milk is a group that may be termed the hay or potato bacillus. This form peptonizes milk without producing in it changes recognizable to the eye. In many specimens of milk obtained in his own city he found a short, thick, spore-bearing, motile bacillus liquefying blood serum. Even after twelve days this bacillus had no action on the fat or the sugar of milk, but reduced the proteids in milk from 3 to under 1 per cent., with the formation of peptones.

Milk in which this bacillus had grown for twenty-four hours had no effect on adult animals when given by the mouth, but acted fatally on young animals. Studying the milk apart from the bacteria to determine what the toxic substance might be which was present, he found that the filtrate was harmless, and therefore concluded that the toxic substance was contained in the bodies of the bacilli. Sterilization at 100° C. at once removed the poisonous properties, but, and this is a point of interest, the spores persisted, and if the milk was still further kept it rapidly regained its poisonous properties as it again became abundantly inhabited by the same species.

It is quite possible therefore that milk sterilized at 60° or even 100° C. may, through the germination of these spore-bearing forms, obtain toxic properties different from those of ordinary sour milk and may thus become a source of grave trouble, if fed to the infant after it has been kept for any prolonged period.

To sum up this hurriedly prepared presentation of the subject, it may be said that milk sterilized by heat is altered to an extent varying according to the elevation of the temperature used in the sterilization and the duration of its exposure, in the following respects:

1. Its proteids are modified, and rendered apparently less digestible; but our knowledge on this subject is still indefinite and dependent chiefly on clinical experience; nothing has yet been proved by laboratory experiment.

2. The combination of its saline ingredients with the proteids, a combination which we must admit is not absolutely proved, but which appears to be extremely probable, is more or less broken and the salts assume a condition in which they are less readily absorbed.

3. Natural ferments whose presence in milk may with much probability be inferred, and which may materially assist its digestion in the infant's stomach, are destroyed.

4. An alteration takes place in the emulsion, normal to milk, which may also have a distinct effect in lessening the digestibility of cow's milk by the infant.

Again, it is extremely important that milk after sterilization should be kept at a continuously low temperature, and it is to be remembered that the employment of

sterilized milk which has been kept for many days is not free from danger.

It appears to me therefore extremely desirable in infant feeding to use fresh milk drawn with such careful precautions as to be practically free from extraneous bacteria, and in which the lactic-acid producing bacteria are present in such small numbers as to induce no alterations of moment.

Such milk in my opinion is better not sterilized at all. But it is seldom our good fortune to be able to obtain such with the regularity necessary for the daily preparation of an infant's food. And when our supply cannot be depended upon, it appears the lesser of two evils to have the milk sterilized, but sterilized at the lowest efficient temperature, namely, 60° C., maintained for fifteen minutes.

Letters received from many of my friends in the American Pædiatric Society advise me that such is almost invariably the practice of the large majority of them.

GALL STONES AND EMPYEMATOUS GALL BLADDERS.

BY EDWIN RICKETTS, M. D.,

CINCINNATI, OHIO.

It is with no small degree of pride that we can refer to the recorded literature on the progress of surgery, with its ebbs and flowings, during its experimental stage and since it has been recognized as an established science. For the controlling of hæmorrhage, the hot iron, boiling oil, and clamp gave way to the ligature, the last-named being at the time one of surgery's greatest triumphs, as given us by the immortal Paré. For this the surgical and medical world stood in awe and rendered him due homage. Now modern special surgery gives us the absorbable ligature, which, having proved its greater superiority and having withstood the numerous crucial tests necessary for its perfecting, has been brought up to the desired standard. It has been accepted as a most worthy addition to our surgical armamentarium, and marks a great epoch in modern surgery that is to outlast tablets of bronze and shafts of granite.

The diagnosis and history of gall stones, with any possible complications, and their empirical treatment; how Bobbs, in 1868, accidentally performed cholecystotomy after the gall bladder had become attached to the adjacent peritonæum; how deliberate surgical intervention was planned and has been brought up to a high state approaching the ideal—these things need no detailed description.

It is important to consider the great secreting capacity of the liver, the product of which must pass through a very small tube or outlet, namely, the common duct. The fact that this same common duct, together with the remaining biliary passages, must, because of its daily tasks, be subjected to great risks—from infection

that may come through its duodenal opening, through its walls, or through the portal circulation, thus causing stenosis, or from furnishing a receptacle for gall stones with infected media, thus often shutting off the bile exit—this is cause sufficient for urging most ardently the necessity of a better understanding of the very dangerous contingencies that present themselves. The ureters in the female are being successfully sounded through the endoscope, as a most valuable aid for the earlier diagnosis of certain of their diseases or of those of one or both kidneys, such as stone, cancer, hydronephrosis or pyonephrosis, etc. The Eustachian tubes, tear ducts, pharynx, larynx, œsophagus, stomach, rectum, male and female urethra, bladder, sigmoid colon, uterus and Falloppian tubes have all been successfully probed as an aid to diagnosis.

As to the causation of gall stones, there has been no definite and well-recognized explanation offered. We are told by men in medicine that they occur most frequently with high livers, those who are found in the higher walks of life, partaking freely of the hydrocarbons together with the free use of stimulants. The recorded observations of men doing gall bladder surgery do not bear out these statements, for the great majority of gall stone operations has been done on subjects found in the common walks of life.

When the presence of gall stones complicated by an empyematous condition of the gall bladder, has been promptly diagnosed, the patient, being advised to rely on internal medication, in which there remains simply a fallacious hope for relief, cries out seriously for a better understanding of the subject at the hands of our profession.

Surgeons no longer poultice and poultice over any region of pus to promote the discharge, but so soon as they are satisfied of its formation and location they advise cutting down and letting it out. The x-ray is used for diagnosing renal and ureteral stone, and when once it is located they incise and remove it.

Drainage of the infected gall bladder by means of a cholecystotomy, if done early, may be followed by brilliant and most satisfactory results and with a death rate of less than one per cent.; while late intervention causes us too often to be compelled to deal with complications that are serious in nature and that necessarily must be followed by a very high mortality. We need clearer and bolder teachings, laying stress on the folly of the internal administration of drugs, which delays and thereby complicate any effort in a surgical way. To let Nature attempt the doing of a successful cholecystotomy or a cholecystenterostomy, is fraught with many unnecessary and very dangerous risks to the patient, which otherwise could have been avoided by well-selected surgical measures.

Gall stones have been found in the hepatic tissue cells, ducts, and gall bladder, and in different portions of the intestinal canal, which is the strongest evidence to prove that they are foreign bodies, and that we should attempt to deal with them as we deal with calculi situated in the kidney, ureter, and urinary bladder.

The principal procedure in surgical intervention, more important than any one of the others named, is cholecystotomy, by which the gall bladder is brought up for stitching to the peritonæum after incision. Drainage through the abdominal and gall bladder incisions must be maintained for weeks or months, or until you are convinced that no stone remains in any biliary space that can be explored by a probe specially adapted to this work.

In a recent case, after removing a number of calculi following on a cholecystotomy in which I am certain that I did not permit any to remain in the common or cystic duct, I was rewarded six months later for having kept up drainage, by a calculus the size of a French pea rolling out on to the dressings. This must have made its post-operative escape from the hepatic duct, in due time escaping through the gall bladder and abdominal wall sinus. The patient was in the best of health.

There is one class of cases, those of empyema of the gall bladder due to infection, which may obstruct the bile flow, and if let alone, may cause secondary infection of the hepatic tissue, thus crippling it for any future function of a complete kind. On the other hand, when an hepatic abscess does result and its contents escape into the stomach, duodenum, or small intestines, it is doubtful if the affected liver tissue ever returns to its former activity. These are the cases demanding just as early drainage of the gall bladder as possible in order that an early convalescence may be established. A periodically over-distended urinary bladder that has not been promptly relieved is sure, in time, to have infection that may extend upward and along the walls of the ureters, affecting seriously one or both kidneys.

A similar condition may exist in the hepatic ducts, until the liver, like the kidneys, may drown itself in its own infected fluid.

To poultice over the region of an empyematous gall bladder, with or without gall stones, is just as futile as a curative measure as it would be to poultice over the region of a cerebral, cerebellar, or pontine abscess.

Nothing save a degree of misleading comfort can come from such a procrastinating effort, which from delay will undoubtedly complicate the situation by causing a possible constitutional metamorphosis that may eventually end in the death of the patient.

Much has been written as to the method of doing a cholecystotomy, by first opening the abdomen and stitching the gall bladder to the peritonæum, permitting it to remain thus for seventy-two hours or until it has adhered to the peritonæum, before incising for drainage or for the removal of calculi that may be present. This procedure should be roundly condemned, along with that of exploration of the gall bladder by introducing the exploring needle through the abdominal and gall bladder walls. The Murphy button for the doing of a cholecystenterostomy is a very ingenious device, and is specially applicable in intestinal anastomosis; but in cholecystenterostomy it has its limitations and objections. In cholecystenterostomy the risks to the bile ducts and liver, of in-

fection coming from the intestine, are increased and should not be overlooked. The button *in situ* is a foreign body and has been found in the gall bladder any number of times on the postmortem table. In any case in which death does not take place and the button remains in the gall bladder, it must in time act as a nucleus for the possible formation of a gall stone. This is a feature that is as objectionable as the permitting of calculi to remain in the gall bladder after cholecystenterostomy has been done by button or suture. Should the gall bladder be contracted, it must rest with the operator, after the abdomen has been opened, to decide between cholecystectomy and intestinal anastomosis with the button; but in all cases where it is possible to do a cholecystotomy, I would surely advise doing it, for then the gall bladder wound is in hand for any desired length of time, for drainage and for the recognition of any calculi that may be overlooked at the time of operating, or for any stone that may roll out of the hepatic duct, days, weeks, or months afterward. If a cholecystectomy has to be considered, it is to be accomplished with greater ease than if it has to be done after a cholecystenterostomy; for then we are compelled to dissect the gall bladder from the intestine and from around the intestinal opening, after which this opening must be closed.

Cholangiostomy has received but little attention at the hands of surgeons. It is seldom a justifiable procedure. In the doing of a cholecystotomy, a median incision, three or four inches in length, directly over the gall bladder, is large enough, in the majority of cases, to work through. It is difficult, after having resorted to the crescent-shaped incision, in which the muscular fibres have been deliberately cut in two, to be able to coapt the ends successfully in suturing, on account of the contractility of the longitudinal muscular fibres. This condition is not present in dealing with the ordinary longitudinal incision suggested. With the abdomen once opened and with all hæmorrhage controlled by means of the hæmostatic forceps, which, after they have effected this object, are to be removed with the index and middle fingers of one hand, generally the right—explore by sense of touch, locating any calculi that may be in the common or cystic duct or gall bladder. By the sense of touch alone you can ascertain if you have a distended or contracted gall bladder, and if you have single or multiple calculi, to deal with. You can decide if you have infection with calculi or not, and if your operation must be a cholecystectomy, cholecystotomy, or a cholecystenterostomy. Some livers are readily lifted toward the abdominal peritonæum by means of the index and middle fingers making upward pressure on the under surface of the liver from within the abdomen and through the abdominal incision, while some will not respond to this pressure. With a moderately distended gall bladder in which no stone can be located, first resort to massage, milking the gall bladder downward, for in some cases you can reestablish a patulous common duct by forcing out small calculi together with plugs of mucus through the

common duct into the duodenum. The writer has done this successfully in four cases.

If this fails in any case in which calculi are found and felt through any of the duct walls, then pack long and warm strips of carbolated gauze, from three to five per cent., around the gall bladder and well down into the abdominal cavity.

If calculi with a moderate amount of fluid are to be removed, the gauze will take up the fluid and prevent it from coming in contact with the field of operation after the gall bladder incision has been made.

When all the calculi are removed, the bladder can be syringed out freely with warm water, and in doing this you will frequently wash out small calculi. To me this has been an agreeable surprise, and I invariably make use of this measure until a quart or more of warm water has been used. After this, the gall bladder is mopped out with packings of carbolated gauze, preferably long, narrow strips, as the shorter pieces may be easily lost sight of. With this accomplished, the incised gall bladder is stitched with interrupted silkworm-gut sutures, one needle hole through the gall bladder, peritonæum, muscle and skin, tying the same gently so as to close the upper and lower angles of the abdominal incision to the upper and lower edges of the gall bladder, until that viscus is stitched into the abdominal incision similarly to the pocket in the garment. A good-sized glass tube for drainage is placed in the bladder, in similar manner to the placing of one in the abdominal cavity for drainage, so that the bladder can be flushed with the patient on his side. A long, olive-tipped, metal probe is always used through the drainage tube for probing the gall bladder and common duct, previous to, and following on any flushing of the gall bladder, in order that any calculi may possibly be disturbed and removed. If any calculi are impacted in the common duct and you are not able to dislodge them so as to push them up into the gall bladder or down through the common duct into the duodenum, you have the choice of one or two procedures: (1) You may break it up by the needling process, which consists in holding the walls of the duct containing the calculi firmly between the index finger and thumb of one hand, while, grasping a strong, straight needle with the fingers of the other hand, you force the point of the needle through the duct wall and into the stone, breaking it into as small fragments as possible; after which you may try to force the fragments up into the gall bladder; by this process they can be removed through the incision in the gall bladder. Or (2) if the stone is too hard for needling, you may incise longitudinally the common duct wall directly over the stone to be pressed out, after which the incision can be stitched up with fine silk or catgut, or you may let it remain open, packing the wound for drainage as suggested by Dr. W. E. B. Davis, of Birmingham, Alabama.

In stitching the gall bladder into the abdominal incision, the greatest care should be exercised in selecting suture material (silkworm-gut is preferable), for a knot

or piece of silk or knot of catgut may drop or work its way into the gall bladder, and may act as a nucleus for the formation of gall stones.

So far, the death rate following incision of the common duct is high, some placing it at thirty-three per cent., while others place it at fifty per cent. The writer's experience in dealing with this class of cases is fifty per cent. With cancer of the liver, or common and hepatic ducts, recognized after the abdomen has been opened, we can do nothing more than close up the abdomen.

If the cancer is confined to the common duct, a cholecystotomy may be considered if the gall bladder can be brought up to the abdominal peritonæum; if not, a cholecystenterostomy by suture or Murphy's button is to be considered, with the hope of some degree of comfort and the possibility of prolonging life.

As to the possible recurrence of gall stones demanding secondary surgical intervention, not enough time has elapsed since the recognition of gall bladder surgery to make any definite and well-authenticated statements.

The few cases in which there has been a recurrence have been duly recorded and reported on; but they have been very few, so few that they may be cited as exceptions to the rule.

With a cholecystotomy as a primary operation for the removal of gall stones, I am quite sure that, in the few cases in which there may be a recurrence, they can be dealt with more successfully by a secondary cholecystotomy, if need be, than by any one of the procedures named for their primary removal.

APPENDICITIS IN THE FEMALE.

By FLOYD WILLCOX McRAE, M. D.,

ATLANTA, GEORGIA.

In a very exhaustive article, a review of the history and literature of appendicitis, published in the *Medical Record*, vol. lxi (1899), page 272, Dr. George Edebohls says: "The history of appendicitis, up to and including the year 1898, embraces more than 2,500 journal articles, dissertations, and books," all but a very small fractional part of which he had consulted in the original. "As regards both the frequency of appendicitis and its relative frequency in the two sexes, the most remarkable and apparently irreconcilable statements are made by various investigators. While the belief is current that appendicitis affects males in larger proportion than females, Einhorn, in 18,000 successive autopsies, found perforating appendicitis in 55 per cent. of males and 57 per cent. of females, and Robinson, in 128 autopsies as they came, found evidences of past peritonitis on and about the appendix in 68 per cent. of female, and 56 per cent. of male bodies. Witt quotes Taft as finding in 300 autopsies, 190 entirely normal appendices, and 110 appendices presenting more or less evidences of disease." Clinically, Edebohls finds that four per cent. of all wom-

en have appendicitis. On the contrary, Deaver says that eighty per cent. of all cases occur in males. The reasons for the relative exemption of females are found in their less frequent exposure to the inclemencies of the weather and other deleterious influences, and in the better blood supply of their appendices. Bland Sutton, in the *Clinical Record* of London, vol. 15, page 321, published in 1899-1900, in an article on Appendicitis, states that it was formerly believed that appendicitis was almost peculiar to males. The large number of accurate observations relating to diseases of the vermiform appendix now available makes it clear that appendicitis is three times more frequent in males than in females. He cites twenty cases in females in which he removed the appendix in a period of eighteen months; these patients all recovered, and were known to be alive and well two months after the operation. He says further: "It is a remarkable fact in connection with troubles on the right side of the abdomen, whether acute or chronic, especially in women, that there is often the greatest difficulty in deciding whether they have their origin in the gall-bladder, the kidney, the cæcum, vermiform appendix, ovary, or Falloppian tube. A careful study of appendicitis in women demonstrates that the clinical aspects of this disease are even more protean than in men. In those women vaguely classed as hysterical, neurotic, or neurasthenic, who complain of indefinite pain in the pelvis, often ascribed to ovarian trouble, the source of the misery, in a fair proportion of instances, is chronic appendicitis." In the *Medical Record*, vol. 51, page 422, Dr. Villar, of Bordeaux, insisted on the frequency of the relation in time between appendicular attacks and menstrual periods. Diagnosis, he said, was the important point. Appendicitis might be confounded with an inflammation of the annexa, and *vice versa*, or they might coexist. He reported several illustrative cases.

Dr. O. Hermes (*Deutsche Zeitschrift für Chirurgie*), in 671 cases gathered from the statistics of various authors, as Bamberge, Voltz, Marchall, Paulier, Martin and Fitts, Sonnenburg and Rotter, finds that of these 671 cases, 186 were in women, that is, 27 per cent. Sonnenburg calculates from his material, that 40 per cent. of subjects were women; Tallamon, 35 per cent. He calculates from the annual reports of the city hospitals of Berlin that of all cases of appendicitis, amounting to 1,577, 949 were in males, and 628 in females, a proportion of about 40 per cent. of females. He says, however: "But indeed it may be said against a purely statistical consideration of this question, with much reason, that a defect of its value consists above all in this: that in the female sex the appendicitis is frequently not recognized, and that so many of the cases of disease of the vermiform appendix go under the diagnosis of uterine or perimetritic disease."

I have quoted quite liberally from these eminent authorities to show the divergence of opinion as to the relative frequency of appendicitis in the male and in the

female. In practically all the cases that have come under my observation in the female, mistakes have been made in diagnosis by myself or by the family physician, or by both. Almost all the attacks have occurred at, or about, the menstrual time, and most of them have been diagnosed as "inflammation of the tube or ovary." The appendix is frequently a pelvic organ in the female and is often not only closely attached to the ovary by the appendiculo-ovarian ligament, but, when either the appendix or the right ovary or tube has been the seat of inflammation, firmly bound to it by adhesions, making a diagnosis extremely difficult. In cases II, III and X, reported farther on, the appendix and the right tube and ovary were involved. In cases I and VI, the appendicular trouble was complicated with movable kidneys on the right side. The subjects in cases IV and XIV suffered with recurring appendicitis and attacks of renal colic before or after the removal of their appendices. I have records of forty-nine cases of appendicitis seen within the last sixteen months, twenty-nine occurring in males and twenty in females, or a little more than forty per cent. of women. During the same period I have operated for appendicitis thirty-two times, sixteen times in males and fifteen times in females, or nearly forty-seven per cent. of females. I have reported these cases, giving the important details, to emphasize the difficulties of diagnosis. In several of them, treatment directed to the genitalia had been carried on systematically without giving any relief, while the removal of the appendices brought about a cure. In others, the ovaries and tubes had been removed, and still the symptoms persisted until relieved by appendectomy. I feel sure that the great disparity in statistics as to the relative frequency of appendicitis in the male and in the female, is due, in large measure, to mistakes in diagnosis, *i. e.*, the disease is frequently overlooked in the female. It is very much more difficult to make a diagnosis of appendicitis in the female than in the male. I do not believe sufficient stress has been laid upon the fact that appendicitis in women usually occurs at or about the menstrual time. Many of us have been accustomed to attribute all abdominal or pelvic pain, occurring at this time, to some trouble with the genitalia; and this is the argument with which we are frequently confronted when the diagnosis of appendicitis is made in this class of cases.

The pain of appendicitis is more sudden in its onset, and very much more acute than that of pelvic disease. It is frequently accompanied with nausea and sometimes with vomiting; muscular spasm is usually marked in appendicitis, practically absent in beginning pelvic disease. The general disturbance is very much greater, and the progress more rapid in appendicitis than in pelvic disease. An intact hymen argues very strongly for appendicitis. When in doubt, and the symptoms are aggressive, it is much safer to make a diagnosis of appendicitis and operate, than to delay until the case is hopeless.

Carstens, in the *New York Medical Journal*, vol. lxi.

page 17, says: "It is astonishing how frequently physicians will diagnose appendicitis if they are only on the lookout for it. No matter what the abdominal trouble is, or whether your diagnosis is diseased tubes, or gall stones, or renal calculi, intussusception or invagination, or typhoid fever, I would reiterate what I have said so often: 'In every attack of abdominal trouble, no matter if it is in old or young, male or female, look again and see if it is not a case of appendicitis.'"

In cases I and VI, I did the combined operation of appendectomy and nephrorrhaphy through the same incision. Case I, I reported in detail at the meeting of this association in New Orleans last year. I had the opportunity of examining the patient a week ago; she was apparently in perfect health, the kidney was in good position, she is absolutely free from abdominal pain, and has gained from fifteen to twenty pounds in weight.

The patient in case VI was operated on four weeks ago, and made an uninterrupted recovery; she is now up, and is apparently in excellent condition. I have demonstrated, in these two cases, the feasibility of this procedure, and I believe it has a field of application in a certain limited number of cases.

Interval Operations.

CASE I.—Miss J. M. L., aged twenty-nine years, Atlanta. Operation, Grady Hospital, October 17, 1900. For a number of years the patient has had a burning sensation in the epigastrium, and regurgitation of food after eating. Trouble with the right kidney (floating) since falling from a street car five years ago. Nephrorrhaphy three years ago; she fell down steps subsequently and broke it loose; since then the kidney has "felt large and in the way." Eleven months ago she was nauseated and vomited for five or six days; had severe pain in the right side of the abdomen, where there was a very tender mass; the abdomen was distended, and it was several days before the bowels moved. In bed two weeks. Had uneasiness and heavy feeling over appendiceal region until six months ago, when she had a similar attack. The ovaries and tubes were removed four years ago. Admitted October 12th for operation. Temperature 98° F., pulse 94. She was nauseated and complained of pain in the side at times until operation. Combined appendectomy and nephrorrhaphy. Recovery. The case has been previously reported. The patient was examined about a week ago; kidney in position; health apparently perfect; no pain or uneasiness. She had gained fifteen or twenty pounds in weight.

CASE II.—Mrs. W. C. T., Isabella, Tenn. Operation, Dr. Stockard's Private Infirmary. First operation in October, 1899, for ruptured tubal pregnancy. Recovery with persistent fistula where drainage had been left. Second operation May 10th. Fistulous tract dissected out, cyst of the broad ligament removed, together with a chronically inflamed, and very much enlarged appendix, surrounded by dense adhesions and adherent to the broad ligament. The diagnosis in this case at the time of the first operation was "acute appendicitis with abscess," and the recovery from the first operation was exceedingly tedious; the patient, who was profoundly septic before the operation, recovered very slowly, with a septic temperature and pulse for several weeks. Whether ap-

pendicitis existed at this time or not, I am unable to say. Recovery from second operation was tedious, but uneventful and complete.

CASE III.—Miss B. C., aged twenty-one years, Atlanta. Operation, "The Halycon." The patient was seen in consultation with Dr. Sommerfield. There was a history, extending over a period of two years, of indefinite abdominal pain, involving the whole right side from the liver to the pelvis. No definite diagnosis was made, and an exploratory operation was advised. This was done September 7, 1899, with the assistance of Dr. Sommerfield and Dr. Holmes. The appendix was chronically inflamed, surrounded by extensive adhesions extending from the cæcum to the liver upward, and downward into the pelvis, involving the right tube and ovary. The right ovary was as large as a lemon, and the right tube thickened and distended. The appendix, tube and ovary were removed, and the adhesions tied off. The patient made a tedious recovery, developing a left saphenous phlebitis about ten days after the operation.

CASE IV.—Mrs. F. M. H., aged forty-two years. Operation, Grady Hospital. Eight or ten weeks prior to admission, the patient had some pain in the right side of the abdomen, the urine contained much sediment, and it was thought that she passed a small calculus from bladder. Last January she had an attack with pain in right iliac region, nausea, and vomiting, for two weeks. From this time on, she lost considerable flesh, had almost constant uneasiness in right side of the abdomen, and three slight attacks as in January, the pain being principally posterior. One week before admission the pain was more severe than ever before; some distention; general abdominal tenderness, more marked about McBurney's point; frequent nausea. The urine for a year contained much pus at times, but not especially so during attacks of abdominal pain. The temperature and pulse varied little from normal, being 98° and 88° F., respectively, on admission.

Operation, May 21st. The appendix was found bent upon itself, lying backward and outward, behind the cæcum; the mesoappendix was half an inch thick; there were varicose veins on the appendix, and recent adhesions between appendix and intestine. Appendix removed; gridiron operation. Recovery uneventful. The patient subsequently passed two small renal calculi, since which time she has been in excellent health.

CASE V.—M. I. (colored), aged fifteen years, single; Atlanta. Operation, Grady Hospital. The patient had good health up to last Christmas, but has had attacks like present every month since December, 1899, always within a few days of the menstrual flow, either before or after. This is the worst attack she has had. She was taken sick three days before admission with faintness and pain in the abdomen below the umbilicus and in the right iliac region, which has not been general; has vomited once, after taking medicine on the night of onset. On admission, temperature 100.2° F., pulse 100, respiration 22. Slight tenderness in the right iliac region; no distention; a mass the size of index finger, running obliquely downward and inward from McBurney's point; slight thickening of the left tube; retroversion. The temperature and pulse remained normal, after the day following admission; the bowels were kept open by an occasional dose of salts; some tenderness remained in the side, with occasional pain. Operation, August 20th, with two-and-a-half-inch incision slightly to outer side of McBurney's point (gridiron). The appendix was found in the posi-

tion of the mass felt externally; the vessels of the appendix were congested, with two slight strictures and a small band of adhesions; the mesoappendix and adhesions were tied off with No. 1 catgut, and the peritoneal cuff dissected back; the appendix was tied off with kangaroo tendon, stump cauterized, etc. Kangaroo-tendon and catgut closure. Primary union. Temperature 99° to 100° F., and pulse 88 to 108, the first two days; thence both normal. Discharged cured September 8, 1900.

CASE VI.—Mrs. J. D. P., Griffin, Georgia. Operation, St. Joseph's Infirmary, October 21, 1900. A large, chronically inflamed, and adherent appendix was removed and a floating kidney stitched back through the same incision; a stab wound in loin for drainage; incision closed in layers; recovery complete. The history of this case preceding the operation is exceedingly interesting. Mrs. P. had suffered for years with chronic indigestion and acute abdominal pain, but never associated with much elevation of temperature or other constitutional disturbance. A diagnosis of "kidney disease" had been made, and she had received local treatment without much benefit. The appendix was so enlarged that it could be readily felt through the abdominal wall, and the kidney was freely movable. I am inclined to think that the floating kidney preceded the appendicitis, perhaps bearing a causative relation thereto.

CASE VII.—Miss I. H., Atlanta, Georgia. Operation at the patient's home. A history of attacks of pain coming on at each menstrual time for three or four years; sometimes so severe as to require morphine. The patient had had two attacks of abdominal pain, with nausea, vomiting and marked collapse, one of which was followed by a great deal of constitutional disturbance and fever for several days. The family physician made a diagnosis of "inflammation of the right ovary and tube." I saw the patient independently of the family physician, and made a diagnosis of chronic appendicitis, with probable involvement of the right tube and ovary, and advised operation. Operation was done November 1, 1900, and a small, but very much inflamed and extensively adherent, appendix was found low down in the pelvis, attached to the right ovary. Ovary and tube normal. Recovery uneventful. An unqualified diagnosis in this case was practically impossible.

CASE VIII.—Miss A. K., aged thirty years. Operation, St. Joseph's Infirmary. A history of one moderately severe attack of appendicitis about nine months ago, and a mild attack two weeks ago. Operation, November 3, 1900. The appendix very much enlarged and distended, the mesoappendix much thickened, and extensive adhesions. Appendix removed. Tubes and ovaries normal. Recovery uneventful.

Operations during Acute Attacks.

CASE IX.—Miss M. D., aged twenty-seven years, Abbeville, Georgia. Operation, May 19, 1900. No history of a previous attack; a history of pelvic trouble extending over a period of several months, for which the patient had had local treatment. On May 13th, she was taken with violent general abdominal pain, nausea and vomiting; pain soon became localized in right iliac fossa. The temperature ranged from 100° to 103° F. from the 13th to the 18th. I saw her on the afternoon of the 18th and found a tumor in the right iliac region. Diagnosis, "acute perforative appendicitis with abscess." Immediate operation was done, with the assistance of Dr. Moye, Dr. Googe and Dr. Maynard; incision into abscess con-

taining from eight to twelve ounces of very foul pus; gangrenous appendix containing concretions; appendix removed, pus cavity cleansed, upper portion closed with through-and-through silkworm-gut sutures; cavity packed with iodoform gauze, which was brought out at lower end of wound. Recovery uneventful.

CASE X.—Miss M., Charleston, S. C. Operation, St. Joseph's Infirmary. The patient was first seen in consultation with Dr. Clark and Dr. Smith about May 10th, at Jackson Hotel. History of an acute attack of abdominal pain, occurring about the menstrual time, five days previously. Temperature ranging from normal to 104° F. Great pain, marked abdominal tenderness, muscular spasm, greatest in the right iliac region. Diagnosis in doubt. On account of aggressive symptoms, the patient was removed to St. Joseph's Infirmary, where an operation revealed an inflamed appendix, surrounded by adhesions, and adherent to a large abscess involving the right ovary and tube. The appendix, ovary, and tube, were removed, the cavity cleansed thoroughly, and the wound closed without drainage. Recovery was very tedious. At the next menstrual time, the tube on the opposite side became enlarged, and the temperature ran up to 103° F., but under free purgation (saline) the inflammation subsided and the patient made a complete recovery.

CASE XI.—Mrs. E. L. G., West End, Atlanta. Operation, St. Joseph's Infirmary. The patient was first seen in consultation with Dr. W. B. Parks, June 20th, on the fourth day of attack. A history of two mild colicky attacks, which were not diagnosed as appendicitis. Temperature 103° F., pulse from 120 to 130. Abdomen tense and tympanitic. Diagnosis, "appendicitis with beginning general peritonitis." The patient was removed to St. Joseph's Infirmary, where an immediate operation was done. Appendix very long, acutely inflamed, with no macroscopic perforation. Acute fibrinoplastic peritonitis, involving the whole lower segment of the abdomen and pelvis; uterus, ovary and tubes, normal. Appendix removed; abscess cavity washed out with large quantity of hot normal salt solution; fibrinoplastic material wiped off with gauze sponges. Incision closed with through-and-through silkworm-gut sutures, without drainage. Recovery uneventful.

CASE XII.—Mrs. R. I. A., West End, Atlanta. Operation, St. Joseph's Infirmary. The patient was seen in consultation with Dr. M. G. Campbell on the night of June 30th. A history of repeated attacks of recurring appendicitis, with more or less constant pain and disability. The abdomen exquisitely tender and tympanitic; the greatest tenderness in the right iliac fossa. Temperature 102° F., pulse 110. I decided on immediate operation, had the patient removed to St. Joseph's Infirmary, and operated at 4 A. M., July 1st. I found the appendix acutely inflamed behind and to the outer side of the cæcum, and imbedded in the mesocæcum. The appendix was removed with considerable difficulty. Local toilette of the peritonæum, the wound being closed in layers without drainage. Recovery uneventful.

CASE XIII.—A. D. (colored), Atlanta, Georgia. Operation, Grady Hospital, August 17, 1900. The patient had malaria three months ago; dysmenorrhœa, frequent leucorrhœa for the last year; night sweats for the past month. No previous attack like present. A week previous to admission (August 17th), she drank a large quantity of ice water. This was followed by some general pain in the abdomen, the bowels moving freely, a few hours after which, pain in the abdomen became sev-

ere, and finally localized in the right iliac region; the pain was constant, with sharp exacerbations, up to admission; she has vomited daily since the onset; temperature, variable, not exceeding 102° F.; the bowels kept open by salts. On admission, 11.40 A. M., temperature 102.3° F., pulse 120, respiration 28. Pain and tenderness in right iliac region, muscles tense, slight distention. A mass, about 3 by 5 inches, in the right iliac region. On examination, the urine contained a very few granular casts; no albumin; on 3d, a trace of albumin, no casts. The temperature in the afternoon reached 103.4° F., pulse 112. An alum enema given at 7 P. M. was slightly effective, one at 8 P. M. effective; turpentine stupes were kept on constantly. The following morning the temperature was 103.4° F., the pulse 116. Operation at 9 A. M. Abscess cavity opened, with free discharge of foul-smelling pus. A necrosed appendix, which contained concretions, removed. Abscess cavity, thin-walled, connected freely with cæcum by appendix. Cavity sponged out with saline, and packed with iodoform gauze; drainage tube inserted, silkworm-gut sutures at each end of the wound, moist saline dressing.

Free discharge of pus at each dressing. On 9th the cavity was irrigated with hydrogen peroxide and saline solution; the tube left out, and a light iodoform packing of cavity made. On 10th the dressing was partly saturated with pus and slate-colored fæces; the wound was lightly irrigated with boric acid and repacked. On 11th, more fæcal matter in and around the wound, which was, however, cleaner; most necrotic tissue gone. No fæcal matter on the 13th. From this time on the discharge gradually diminished, the wound, closing to unhealthy granulations about one fourth inch deep, was curetted and sutured on September 10th, healing readily.

Afternoon of operation, temperature 103.2° F., pulse 120. The following day, temperature 101.4° F., pulse 116. Both remained normal after the third day. Discharged cured September 19th.

CASE XIV.—Mrs. P. H. C., Atlanta. Operation, St. Joseph's Infirmary. The patient was first seen in consultation with Dr. C. E. Boynton, September 11th. A history of one or two mild colicky attacks; temperature 101° F., pulse 100; general abdominal pain. A history of violent pain, with nausea, vomiting, and subnormal temperature, followed by a rise in temperature and increased pulse rate. The patient was moved to St. Joseph's Infirmary; operation September 12th. The appendix, bound by adhesions and acutely inflamed, was removed, and the wound closed in layers. Recovery uneventful; the patient has had an attack of renal colic since, passing three calculi.

CASE XV.—Miss I. D., aged twenty years, residence Atlanta. Operation, Dr. Stockard's private infirmary. The patient was first seen in consultation with Dr. Stockard and Dr. Lukens, November 1st. No history of previous attack. She was taken with violent abdominal pain, concurrent with the menstrual flow; pain and tenderness low down in the pelvis, just above, and to the right side of the pubis, but gradually extending upward into the loin. Diagnosis in doubt. Operation suggested, but delay insisted upon. Marked increase in all the symptoms. The patient was moved to Dr. Stockard's private infirmary; operation on the morning of November 4th. Large, gangrenous appendix, containing concretions and three perforations, surrounded by abscess containing about eight ounces of very foul pus; several

large, dark spots on cæcum. Appendix removed; upper portion of the incision closed with through-and-through sutures, and drainage left at lower end.

The patient getting along well, with small fæcal fistula diminishing in size daily. (Fistula ultimately closed.)

PHARYNGEAL ADENOIDS, THEIR FREQUENCY AND SEQUELÆ.

BY PHILIP D. KERRISON, M. D.,

NEW YORK,

ATTENDING OTOLOGIST, UNIVERSITY AND BELLEVUE MEDICAL COLLEGE
CLINIC.

THE so-called pharyngeal tonsil is a physiological structure, and it is only when it becomes unduly enlarged, or hypertrophied, that its presence can be looked upon as a pathological condition.

Normally, it cannot be appreciated by inspection by reflected light, nor by the palpating finger, nor does it produce symptoms. When, however, either through engorgement of its vessels, or increase of its connective tissue, it becomes sufficiently enlarged to produce the smallest degree of obstruction to nasal respiration, it must be looked upon as an abnormal condition involving many dangers to the patient's future development and physical well-being.

In the present paper, the writer lays no claim to having any original matter to present, his purpose being rather to emphasize certain facts, well known to those who have given the subject special study, but which are, perhaps, not sufficiently recognized by the profession at large.

Cases in which the pharyngeal growths are of very large size may present objective symptoms so characteristic and familiar as to require no description. When a child habitually breathes through the mouth, wears a dull and rather vacant expression of countenance, is peevish or listless in manner, presents symptoms of nasal catarrh, where the general appearance is suggestive of anæmia or malnutrition—given such a picture, the physician's mind will at once revert to a nasopharyngeal growth as the most probable of underlying causes.

These are not the most dangerous cases, for in the multiplicity of symptoms there is safety to the patient, as they demand and insure prompt and decisive treatment. But, unfortunately, only a very small percentage of cases present this formidable and suggestive array of symptoms. In the great majority of cases, the growth in the pharynx produces only partial obstruction to the passage of air through the nasal cavities, and is accompanied by but few symptoms, and these the reverse of pathognomonic. That these cases are often presented to the family physician, and are treated unsuccessfully because the underlying cause has not been suspected, there can be no doubt.

Many of the sequelæ of this condition have been sketched so often in text-books and medical journals that their repetition would seem unnecessary. The arrest of

development that occasionally follows the development and neglect of these growths is such as may result from a more or less complete nasal obstruction due to any cause. The characteristic changes in the facial expression are supposed by some to be due in part to anatomical changes in the superior maxillary and palate bones; and these anatomical changes are supposed to be produced in the following manner: The exaggerated inspiratory efforts when the patient attempts to breathe through the nose, and the inadequate amount of air passing through the nares, cause rarefaction of the air in the pharynx, with the result that the alveolar arches are drawn inward toward each other, and the upward arch of the hard palate is increased. Should the adenoid growths be allowed to remain until after the second dentition, the above changes may be more pronounced, and the permanent teeth may be crowded together and protrude to a noticeable and disfiguring degree. As a result of the forcing upward of the hard palate, the floor of the nose is elevated, giving rise to a deviation of the nasal septum later in life. The narrow chests, delayed general growth, and the appearance of weakness, making the little sufferers appear younger than they are, are also well known as conditions characterizing extreme cases.

But while the above anatomical changes unquestionably do exist in certain cases as a result of naso-pharyngeal growths, they are probably exceptional rather than the rule; and it is undoubtedly true that pharyngeal adenoids of large size often exist for a considerable length of time without producing any such marked physical signs. To depend, therefore, upon any classical train of symptoms or group of physical signs for the diagnosis of these growths, would be to let many cases pass before our eyes unrecognized.

A class of symptoms well known to follow hypertrophy of the pharyngeal tonsil is that due to catarrhal inflammations in neighboring portions of the upper respiratory tract. Dr. Bosworth (1) has called attention to the fact that "acute rhinitis is comparatively rarely met with in a child, and that in such cases it is really suffering from a subacute inflammation of the pharyngeal tonsil." The secondary rhinitis is probably due to irritation from retained nasal secretions, and occurs whenever, from exposure, the pharyngeal growth becomes temporarily enlarged. The frequent attacks of epistaxis, which are thought by some to be characteristic of adenoids, probably occur as one of the symptoms of the secondary rhinitis before referred to. That *pharyngitis*, *laryngitis*, *tracheitis* and *bronchitis* should frequently occur intercurrently with pharyngeal adenoids is not surprising. Remembering that it is among the functions of the nose to filter, and add warmth and moisture to the inspired air before it reaches the pharynx, and that these patients are usually mouth-breathers, at least during a portion of the twenty-four hours, these conditions appear to be logical sequences. When, therefore, a child is more than usually prone to contract any of the above inflamma-

tory conditions of the upper respiratory tract, an examination should always be made, which will enable us either to remove the pharyngeal growth or exclude it as an ætiological factor.

Pharyngeal adenoids are supposed to be the occasional cause of certain conditions usually classed as neuroses. They certainly predispose to such affections as pertussis, asthma and laryngismus stridulus. Eustace Smith (2), of London, is of this opinion, and cites the case of an infant treated by him in the East London Hospital, in whom laryngeal crowing of a type so distressing as to endanger life had persisted since birth. The symptoms completely disappeared within a few days after the removal of a postnasal growth.

That the presence of adenoids in the pharynx adds greatly to the individual's susceptibility to *the germs of tuberculosis and diphtheria* is a fact that has been emphasized by many observers, and if their conclusions are well founded, it would seem that an examination for adenoids, and their removal when found, should be as much a matter of routine as is vaccination as a prophylactic measure against small-pox.

Lewin (3), of Russia, has made two hundred careful microscopical examinations of adenoid growths removed from the pharynx, with reference to the presence of tuberculosis, evidences of the disease being found in nine out of the two hundred cases. Other observers in other parts of the world have made similar investigations with similar results, "the sum total of observations published being 905 cases with 45 tubercular findings," or about five per cent. of the cases examined. In many cases, the patients in whom these tuberculous deposits were found have been absolutely free from any other sign or symptom of the disease.

Plottiers (4), of France, has demonstrated the influence of adenoids in increasing the mortality among children suffering from *diphtheria*. He argues that the presence of a vascular growth at a point in the pharynx most infested with microbes, and the patient's diminished power of resistance, must necessarily increase the dangers of infection and diminish the chances of recovery. Following this line of thought, he held postmortems on thirty-eight cases of children dying of diphtheria in the Hôpital des enfants malades, Paris, and found well-developed adenoid growths in fifty per cent. of the cases examined. In one case, he found the diphtheritic membrane on the vegetations, while the month was completely free.

But perhaps the most important of the train of evils following adenoids are the ear complications, for in many cases it is only by an early recognition of these growths, and their prompt removal, that the little sufferers can be saved from permanent loss of hearing. All authorities agree as to the gravity of these dangers.

Dench (5) states that pharyngeal adenoids "are responsible for more than half the pathological conditions met with in the middle ear."

Bosworth (6) asserts that "the proportion of cases that escape ear trouble is small"; while Kyle (7) holds that at least ninety per cent. of cases of adenoid growths are accompanied by some degree of deafness. Yet, in spite of all that has been written on the subject, it is doubtful whether sufficient thought is given to the importance of guarding against these ear complications. Investigations instituted during the past few years in different parts of the world seem to prove that a very large proportion of existing deaf-mutism had its origin in adenoids during childhood. Jankelevitch (8), at Prague, Austria, examined 158 deaf mutes; and found adenoid vegetations of considerable size in over half (fifty-four per cent.) of them. Wroblewski, of Poland, found pharyngeal adenoids in fifty-seven per cent. of deaf mutes examined. James Kerr Love (9) "found that seventy per cent. of the deaf-mute children of Glasgow had adenoids." In our own country, C. R. Holmes (10), of Cincinnati, has "made a careful examination of 450 deaf mutes in the Illinois State Institute at Jacksonville, and found an abnormal development of the third tonsil in 231, or fifty per cent."

Sendziac (11), of Warsaw, Poland, gives the results of similar examinations by other investigators, the percentages varying from fifty to seventy-three per cent. He also relates the following case from his own practice: A child, five years old, was referred to him as a case of congenital deafness; a brother of the patient, twenty years old, was also a congenital deaf mute; a sister, also congenitally deaf, died in her fourth year. Careful functional examination showed that the child could neither hear nor speak. Palpation revealed the presence of enormous pharyngeal adenoids. The growths were removed under full anæsthesia. Three months later, the child was brought back with the hearing improving, and was rapidly learning to articulate. Arslan (12), of Turin, Italy, operated for the removal of adenoids in two cases of deaf-mutism, "relieving one and curing the other, both as to hearing and speech." In this country, Getchell (13), of Worcester, Mass., records three cases of deaf-mutism, in which he removed adenoids, in one of which cases improvement followed the operation. Jankelevitch sums up the conclusions to be deduced from his investigations somewhat as follows: Without denying the existence of congenital deaf-mutism, he contends that it is much rarer than it is generally supposed to be, and that most cases should be regarded as acquired and due to the presence of adenoid vegetations during infancy.

But, if adenoids are the cause of many cases of deaf-mutism, how much greater is their weight of responsibility in the production of the lesser ear lesions with partial impairment of hearing! That it is great is evidenced by the frequency with which children, brought to the ear clinics with symptoms referable to the ear, have to be subjected to an operation for the removal of adenoids as a preliminary measure of treatment. Addi-

tional evidence that the adenoids and ear symptoms stand in these cases in the relation of cause and effect may be found in the recorded cases of Dr. Haight (14), in which the adenoid growths were confined to one side of the naso-pharynx; in these cases, functional examination revealed impairment of hearing on the side corresponding to that of the growth, the hearing in the opposite ear remaining normal.

The ear lesions first occurring as a result of adenoids are undoubtedly to be found in the conducting portion of the auditory apparatus; *e. g.*, tubal catarrh, tubo-tympanic congestion, acute otitis media, acute purulent otitis, etc., conditions often following each other in the order named. But where the adenoids are allowed to remain, evidence is not wanting of the fact that in many cases the labyrinth also soon becomes involved. Dr. Dench (15) has pointed out that many cases of tubal catarrh accompanying adenoids present, upon functional examination, not the characteristic reactions of that affection, but diminished bone conduction, and sometimes a hyperæsthetic condition of the auditory nerve, "which phenomena indicate an irritative lesion of the labyrinth." The influence of adenoids in the causation of the ear lesions occurring in adult life is not so easy to determine, for by this time all traces of such a growth have usually disappeared. But one cannot avoid the belief that many of the adult patients applying for treatment for some form of chronic otitis are in reality experiencing the results of lesions which have existed from childhood, but which have been so gradual in their development that only in adult life have the symptoms become sufficiently pronounced to attract the patient's attention.

Before leaving the subject, I should remind the reader that adenoids may occur in adults as well as in children. While they are usually developed during childhood, and tend to disappear spontaneously after the thirteenth year, there are many exceptions to that rule, and it is by no means uncommon to find well-developed adenoids in people of adult and even middle life. One of many such cases on record is that recently reported by Dr. Potter (16), where the patient was a woman of forty-seven, and the symptoms complained of were those of impaired hearing and difficult nasal respiration. Examination revealed the presence of a large postnasal growth, which was removed under ether, and proved under the microscope to consist of adenoid tissue. The hearing improved greatly within two weeks after the operation.

As to the treatment, experience has shown that adenoid vegetations, when thoroughly removed, do not as a rule recur, but that when any part of the growth is allowed to remain, the tendency to recurrence is marked. The treatment, therefore, resolves itself into any method accomplishing thorough ablation, or removal. This is best accomplished by the use of the Brandegee, or other suitably constructed, adenoid forceps, which grasps and removes the growth piecemeal or in bulk; the site of the removed growth being then curetted with a Gottstein

curette, which removes any remaining shreds of adenoid tissue. In this operation, thoroughness is of paramount importance, and this is best attained with the patient under the influence of a general anæsthetic.

In conclusion, the writer feels justified from the facts adduced in basing thereon the following conclusions:

1. That pharyngeal adenoids in children are very much more common than they are generally supposed to be.

2. That cases of moderate development are often not recognized.

3. That adenoid growths of moderate size, though not necessarily accompanied by marked symptoms at the time of their development, are often responsible for grave conditions felt during adolescence and adult life.

4. That, unless removed, pharyngeal adenoids are in nearly all cases accompanied by more or less impairment of hearing.

5. That the presence of adenoids adds greatly to the gravity of intercurrent diseases, and increases the patient's receptivity to the germs of tuberculosis and diphtheria; and, therefore,

6. That the periodical examination of children for the presence of adenoids should become a routine measure of prophylaxis.

7. That cases of moderate development, no less than those in which the growths are of large size, demand prompt surgical treatment.

8. That the treatment should aim at complete ablation or removal of the growth, which in most cases is best accomplished with the patient under the influence of a general anæsthetic.

Therapeutical Notes.

A Resolvent for Tuberculous Glands.—The *Journal de médecine de Paris* for December 23, 1900, gives, on the authority of Descroizilles, the following resolvent solution:

℞ Distilled water.....150 parts;
Chloride of sodium..... 40 "
Sulphate of magnesium..... 15 "
Tincture of iodine..... 1 part.

M.

To be applied on compresses.

Ichthyol in Erythema Nodosum.—In the *British Medical Journal* for January 5th Dr. Alexander Brownlie, of Edinburgh, gives this formula:

℞ Ichthyol. 2 drachms;
Alcohol, } each. 3 "
Ether, }

M. S. To be painted on. It is important, he says, that the alcohol and ether be mixed, and then the ichthyol added. He adds that the formula is similar to Boulland's, as given in the *Therapeutische Monatshefte* for January, 1899.

An Enema for Chronic Dysentery.—Delioux de Salignac (*Journal des praticiens*, January 12th) recommends the following formula:

℞ Tincture of iodine..... 10 to 20 drops;
Potassium iodide. 7½ grains;
Water. 8 ounces.

M.

A Lotion for the Night-sweats of Phthisis.—The *Journal des praticiens* for January 12th cites Hirschfeld as having observed excellent results from sponging the body with the following mixture:

℞ Balsam of Peru..... 1 part;
Formic acid, } each. 5 parts;
Chloral hydrate, }

Strong alcohol.100 "

M. It is said that the efficiency of the lotion may be heightened by adding to it one part of trichloroacetic acid.

The Treatment of Sore Nipples.—Dr. Oui (*Medical Press and Circular*, November 28, 1900), at a meeting of the Medical Society of Paris, recommends the prophylactic use of astringent lotions to the nipples during pregnancy. During the nursing period, it is recommended to wash the nipple before and after lactation with a lotion of boric acid. Dr. Oui applies a 1 in 4,000 bichloride solution in the intervals of rest. This should, of course, be removed before the child is put to the breast, and the nipple washed with the boric-acid lotion. When there is much pain, a saturated alcoholic solution of orthoform is recommended in preference to cocaine, which is dangerous.

Treatment of Lupus by Permanganate of Potassium.—M. Butté (*Indépendance médicale; International Medical Magazine*, January) recommends applications of solutions of permanganate of potassium to the affected parts. After ten days an amelioration is observed; the tubercles have flattened, and the disease does not progress. After two or three months nothing remains to be seen but the cicatrix.

Resorcin in Rodent Ulcer.—Williams (*British Medical Journal*, December 1, 1900) has used pure resorcin applications successfully in a rebellious case of rodent ulcer. The treatment extended over two months.

NEW YORK, SATURDAY, FEBRUARY 2, 1901.

A BRITISH CONGRESS ON TUBERCULOSIS.

It is announced that such a congress will be held in the Queen's Hall, London, on July 22d, 23d, 24th, 25th, and 26th. The announcement was issued before the accession of Edward VII to the throne, and the Prince of Wales was mentioned as the president of the congress. Perhaps it is hardly to be expected that the King himself will preside throughout the congress, but, in view of the immense importance of its purpose, the prevention of consumption, it may, we presume, be confidently hoped that he will open it in person. Among the vice-presidents are Lord Lister, Sir John Burdon Sanderson, Sir Hermann Weber, the director-general of the Medical Department of the Navy, the deputy director-general of the Army Medical Department, the president of the Royal College of Physicians, London; the president of the Royal College of Surgeons, England; the president of the Royal College of Physicians, Edinburgh; the president of the Royal College of Surgeons, Edinburgh; the president of the Royal College of Physicians, Ireland; the president of the Royal College of Veterinary Surgeons, the president of the British Medical Association, the president of the Royal Medical and Chirurgical Society, the president of the Society of Apothecaries of London, and the president of the Faculty of Physicians and Surgeons of Glasgow. Among the executive officers are Sir William Broadbent, Mr. W. Jobson Horne, I. B.; Mr. Malcolm Morris, Dr. Clifford Allbutt, and Dr. Alfred Hillier.

Every British colony and dependency is invited to participate in sending delegates, and the various governments of Europe, Asia, and America are invited to send representative men of science and others, who will be the distinguished guests of the congress. The object of the congress is to exchange the information and experience

gained throughout the world as to methods available for stamping out consumption, a disease declared to be the cause of some 60,000 recorded deaths annually in the United Kingdom alone. The work of the congress is to be carried on in four sections, namely, State and Municipal (Sir Herbert Maxwell, president; Dr. Bulstrode, of London, and Dr. James Niven, of Manchester, secretaries); Medical, including climatology and sanatoria (Sir R. Douglas Powell, president; Sir Hugh Beevor, of London; Dr. Hector Mackenzie, of London; Dr. R. W. Philip, of Edinburgh, and Dr. William Calwell, of Belfast, secretaries); Pathological, including bacteriology (Dr. Sims Woodhead, of Cambridge, president; Dr. Wethered, of London; Professor Rubert Boyce, of Liverpool; Dr. E. J. McWeeney, of Dublin, and Dr. Perkins, of London, secretaries); and Veterinary—Tuberculosis in Animals—(Sir George Brown, of Harrow, president; Professor Hobday, of London; Professor Bradley, of Edinburgh, and Professor H. Woodruff, of London, secretaries). In addition, there will be a museum of pathology, bacteriology, and public health, under the charge of a committee of which Dr. Woodhead is chairman, and Mr. Horne secretary. The honorary secretary-general is Mr. Malcolm Morris.

The congress method of dealing with the study of tuberculous disease has already been productive of much good on the continent of Europe, and we look confidently for valuable results from the deliberations of the British gathering. It comes at a time of the year when many Americans are likely to be in Europe, and it may be expected that the medical profession of our country will be amply represented. Nowhere else than here has the struggle against consumption been more vigorously or more successfully carried on, and the physicians of the United States ought to take a prominent part in such a congress as is to be held in London.

CRIMINAL HYPNOTISM.

THE Section in Legal Medicine of the Thirteenth International Medical Congress passed resolutions to the effect that hypnotism and "magnetism" were true therapeutic agents, that their ill-considered employment was capable of leading to serious consequences, that their practice should be restricted to persons possessed of the diploma of doctor of medicine, and that in all countries legislation ought to be so amended or extended as to suppress this illegal practice of medicine, under whatever form or title such psychotherapeutical practices might

be masked. These resolutions were passed at the close of the debate that followed the reading of a report by M. Dupré, who handled the medical aspect of the subject, and M. Rocher, who dealt with it from the legal point of view.

The Criminal Branch of the French Court of Cassation has recently condemned certain hypnotizing charlatans, and *Progrès médical*, in its issue for January 12th, expresses well-grounded satisfaction that the decision of the court was in no small degree influenced by Dupré and Rocher's report. The report was, indeed, a most important and cogent review of hypnotism in its medico-legal aspects. Its teachings are to be borne in mind from several points of view, chief among which are that of the physical and psychical injury done to degenerate, ill-balanced, and feeble persons by repeated hypnotization, that of the parody of justice enacted when credence is given in court to an accused person's plea that his offense was committed under the influence of hypnotism, and that of the infraction of the regulations governing medical practice by hypnotizing charlatans. It was shown in the report that serious physical and psychical conditions might be brought about in certain persons by hypnotizing them, conditions directly dependent on the degree of repetition of the process, on the nervous predisposition of the person, and on the publicity of the sittings.

It was further shown, what has long been well established, that no well-ordered person could be induced by hypnotism to commit a manifest crime. Well recognized as this fact is, it may not be unprofitable to repeat the substance of this portion of Dupré and Rocher's report. It is possible, says M. Dupré, to suggest (in the hypnotist's sense of the word) to certain persons the idea and even the accomplishment of such a crime as robbery, incendiarism, or assassination, but many conditions are required for the success of the experiment. The first of these is that the person shall already have been hypnotized frequently and by the same hypnotizer, so that his "suggestibility" shall have been cultivated, developed, and rendered tractable. The second is that the criminal act shall constitute only a simple offense, such as larceny, lying, etc., or a "laboratory crime." In either case the moral resistance of the hypnotized person remains dormant and the act is committed. When, however, the act suggested is grossly criminal, the hypnotized person resists, and no grave crime has been proved to have been the result of hypnotic suggestion.

There is, of course, an apparent inconsistency when

it is declared possible to suggest to a hypnotized person the actual accomplishment of assassination, and then the additional statement is made that "no grave crime has been proved to have been the result of hypnotic suggestion"; but the inconsistency is not real. The "accomplishment of assassination" may be suggested, but the suggestion will not be carried out; possibly the criminal intention may be entertained up to a certain point, but at last conscience gains the victory. Thus is explained the willingness of a hypnotized person to stab another with a dagger made of paper, whereas he flatly refuses when a real dagger is put into his hand. This form of criminal hypnotism has no existence in the sense that would justify a court in exculpating a person who had committed a felony; the real criminal hypnotism—real when it is not pretended—is that of the charlatan, the *soi-disant* "professor," the "lecturer," the "curer." No civilized community can afford to tolerate this pseudo-science-mongering; still less can it afford to accept hypnotism as a scapegoat for crime.

TRACHEAL INSUFFLATION OF AIR AND MANUAL COMPRESSION OF THE HEART IN SUSPENDED ANIMATION.

PRUS's method of resuscitation by insufflations of air into the trachea and rhythmical squeezing of the exposed heart may certainly be said to be a formidable procedure. It seems that it was originally described in the *Wiener klinische Wochenschrift*, 1900, Nos. 20 and 21. Prus experimented on a hundred dogs which he had killed, or apparently killed, by chloroformization, electricity, or strangulation. His chloroform experiments were twenty-one in number, and in sixteen of them he succeeded in recalling the animals to life. Maag, a Danish physician, has recently tried the method on the human subject (*Centralblatt für Chirurgie*, January 5th).

Maag had occasion to resort to nerve-stretching in a case of sciatica in a young man whose heart was sound, whose urine contained neither sugar nor albumin, and who showed no contraindication to the induction of chloroform anæsthesia. The man had been a hard drinker, but for a year preceding the operation he had wholly abstained from alcohol. The anæsthetization was begun at 8 o'clock in the morning. At the end of ten minutes, during which time the chloroform had been given drop by drop by means of an Esmarch inhaler, the patient was sufficiently narcotized to admit of his being laid on his side and the site of the operation sterilized.

This procedure occupied about five minutes, and the patient was quiet, his respiration and pulse were of good quality, and his pupils were contracted. When the skin was incised, he reacted vigorously, and the anæsthetist was called to give him more chloroform. Only a few drops were given, however, because the man soon became asphyxiated; in all, he had received three drachms and three quarters.

The ordinary means of resuscitation were resorted to, he was soon perfectly restored, and, without any further administration of chloroform, the operation was completed. Again the man was asphyxiated, and traction on the tongue, artificial respiration, blows on the præcordial region, etc., were employed energetically, but without result. After ten or fifteen minutes tracheotomy was performed and air forced into the trachea through a cannula, but in vain; the patient was pulseless, cold, and cyanotic, and he was not breathing. Resection of the third and fourth costal cartilages and of a portion of the ribs was performed, and the flap of skin, muscle, and ribs was turned to one side, when it was perceived that the left pleural sac had been opened. Through this opening the hand was immediately inserted and the heart grasped, together with the pericardium. There was no cardiac action. After a few rhythmical squeezings of the heart, it began to beat, very feebly at first, then stronger and stronger. The squeezings of the heart and the insufflations of air were continued. As the tracheotomy tube did not pass deep into the trachea, some of the air escaped by the nose and mouth, so that these had to be compressed.

After the lapse of about half an hour the first gasping respiration occurred, and it became deeper and deeper, but constant insufflations were required to keep it up. After a time, however, two inspirations followed an insufflation, then three, and so on. At about 11 o'clock the man was able to breathe ten times in succession without assistance, and in half an hour more his breathing was deep and regular, while the heart beat vigorously at the rate of about 70 to the minute, compression being required only now and then. Thereupon the vessels in the wounds began to bleed, and were tied. The pupils were contracted, the color of the face had for some time been natural, and the patient kept his jaws so firmly closed that it was almost impossible to open his mouth. The wounds were now sutured, but that of the thorax was closed only partially, for it was judged that it might be necessary to reopen it for renewed compression of the heart. All danger seemed to be over, but

the patient did not regain consciousness and showed no evidence of pain from the treatment of the wounds. At about 12 o'clock the breathing suddenly grew more feeble and in the course of a few minutes ceased entirely. Again insufflation was resorted to, but in vain. The ordinary expedients, such as artificial respiration, faradization of the phrenic nerve, etc., were employed. Until 8 o'clock in the evening the heart kept on beating powerfully, when it suddenly stopped, and not till then was the insufflation discontinued: the patient was then dead.

Such formidable procedures may seem like training a park of artillery to kill a fly, but this was surely an extraordinary case of chloroform poisoning. The author clings to the idea that Prus's plan of resuscitation is the correct one, and imputed his patient's final death, after apparent recovery, to unfortunate accidental features. To us the case seems an added warning not to use chloroform save in the presence of some positive indication against ether.

THE PUBLIC SPITTING NUISANCE.

It is a source of gratification that at last some steps have been taken, by the arrest and fining of one offender, to show that the ordinances of the health board of the city of New York are meant to be complied with, and are not merely the vaporings of a few harmless enthusiasts. Let the duty of taking steps to prevent the nuisance be responsibly imposed upon officials, and the filthy practice will soon be checked. It is scarcely fair to expect the private individual, however disgusted he may feel at the habits of his hoggish fellow passengers, to risk the unpleasant notoriety of creating "a scene"; though the same individual would doubtless experience no difficulty in carrying out his express orders were he in an official position. It might be a good plan to have a number of small cards printed with the legend, "You are required, under penalty of a fine, to abstain from expectorating in public vehicles or in public buildings," or some other suitable formula. One of these cards might be unobtrusively handed by the official in charge as a reminder whenever he observed the commission of the offense, thus sparing the feelings of the possibly thoughtless offender, and at the same time placing him in the position of a deliberate recalcitrant deserving of no consideration should he repeat it.

THE NEW ZEALAND MEDICAL JOURNAL.

We have received the second number, dated November, 1900, of this handsome new octavo journal of fifty-eight pages of reading matter, edited by Dr. J. Malcolm Mason, of Otaki, and published in Wellington by the New Zealand branch of the British Medical Association. We find the matter contained in it interesting and well presented.

SUGGESTIVE IMITATION IN NEWSPAPER REPORTING.

IT is somewhat interesting to note the wave of hospital scandals which is now breaking, doubtless in consequence of the Bellevue investigation. From Newark, Buffalo, and other places we note that the local newspapers, not to be outdone by New York, have evolved hospital scandals of their own. Much space is covered by good printing ink, but a perusal and collation of the various papers, while it discloses vehement assertion and black headlines, affords singularly little valuable information. It seems as though the occurrence of the Bellevue affair turned the ingenious reporters' attention to that field as one in which some local counterpart ought to be forthcoming, and hey, presto! there it is.

EXCESSIVE VOMITING DUE TO A PESSARY.

APART from the condition of pregnancy, it is seldom that so striking an example of hyperemesis due to uterine irritation is encountered as in a case reported by Wichert (*Deutsche medicinische Wochenschrift*, 1900, No. 47; *Deutsche Medizinal-Zeitung*, December 17th). The patient, thirty-two years old, had worn a Mayer's rubber pessary in her vagina for a long time. The stinking instrument was removed, the vagina was disinfected, tincture of iodine was given internally, and in two days the vomiting had subsided.

SPONTANEOUS RUPTURE OF THE ŒSOPHAGUS.

AMONG the rarest of pathological occurrences must be included spontaneous rupture of the œsophagus. In a case reported by Heintze at a meeting of a Berlin (December 13th) the accident befell a healthy man, forty-three years old, immediately after a meal. He had severe pains in the stomach, went into collapse, and died in seven hours. The rupture, half an inch long, ran lengthwise of the œsophagus, near the stomach. No cause for the accident appeared on gross examination, and the microscope showed only signs of fresh inflammation.

THE EIFFEL TOWER AND THE REDUCTION OF OXY-
HÆMOGLOBIN.

THE influence of changes of altitude on the economy is well known to vary in proportion to the suddenness of the change. If we except Pike's Peak, perhaps nowhere else can the effects of an abrupt change be better studied than in the Eiffel tower. At a recent meeting of the Paris Society of Biology (*Progrès médical*, December 22d) M. Hénocque reported the results of sixty observations, showing an almost constant augmentation of the reduction of oxyhæmoglobin, whether the ascent was made by the elevator or by the stairs. In exceptional instances it was diminished, and then there was panting or dyspnoea. The descent on foot was also accompanied by the augmentation noted in the ascent.

News Items.

Society Meetings for the Coming Week:

MONDAY, *February 4th*: New York Academy of Sciences (Section in Biology) German Medical Society of the City of New York; Morrisania Medical Society, New York (private); Brooklyn Anatomical and Surgical Society (private); Corning, New York, Academy of Medicine; Utica, New York, Medical Library Association; Boston Society for Medical Observation; St. Albans, Vermont, Medical Association; Hartford, Connecticut, Medical Society; Providence, Rhode Island, Medical Association; South Pittsburgh, Pennsylvania, Medical Society; Chicago Medical Society.

TUESDAY, *February 5th*: New York Neurological Society; Buffalo Academy of Medicine (Section in Surgery); Elmira, New York Academy of Medicine; Ogdensburg, New York, Medical Association; Syracuse, New York, Academy of Medicine; Hampden, Massachusetts, District Medical Society (Springfield); Hudson, New Jersey, County Medical Society (Jersey City); Androscoggin, Maine, County Medical Association (Lewiston); Baltimore Academy of Medicine; Medical Society of the University of Maryland (Baltimore).

WEDNESDAY, *February 6th*: New York Academy of Medicine (Section in Public Health); Society of Alumni of Bellevue Hospital; Medical Microscopical Society of Brooklyn; Medical Society of the County of Richmond, New York (New Brighton); Penobscot, Maine, County Medical Society (Bangor); Bridgeport, Connecticut, Medical Association.

THURSDAY, *February 7th*: New York Academy of Medicine; Brooklyn Surgical Society; Society of Physicians of the Village of Canandaigua, New York; Boston Medico-psychological Association; Obstetrical Society of Philadelphia; United States Naval Medical Society (Washington); Medical Society of City Hospital Alumni, St. Louis; Atlanta Society of Medicine.

FRIDAY, *February 8th*: Yorkville Medical Association, New York (private); Brooklyn Dermatological and Genitourinary Society (private); German Medical Society of Brooklyn; Medical Society of the Town of Saugerties, New York.

SATURDAY, *February 9th*: Obstetrical Society of Boston (private).

Infectious Diseases in New York:

We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported for the week ending January 26, 1901:

DISEASES.	Week end'g Jan. 26	
	Cases.	Deaths.
Typhoid fever.....	33	12
Scarlet fever.....	329	22
Cerebro-spinal meningitis.....	0	0
Measles.....	110	2
Diphtheria.....	332	52
Small-pox.....	11	1
Tuberculosis.....	331	185

Naval Intelligence:

Official List of Changes in the Medical Corps of the United States Navy for the two weeks ending January 26, 1901:

BERTOLETTE, D. N., Medical Inspector. Detached from duty as a member of the medical examining board and ordered home.

FISKE, C. N., Assistant Surgeon. Detached from the *Wheeling* and ordered to the *Mohican* when the former vessel goes out of commission.

HASS, H. H., Assistant Surgeon. Detached from the *Isla de Luzon* and ordered to the *Solace*.

RUSH, R. K., Surgeon. Ordered to the Pensacola Naval Station, Florida, for recruiting and other duty.

RUSSELL, A. C. H., Surgeon. Ordered to Washington for duty as a member of the medical examining board.

SHIFFERT, H. O., Assistant Surgeon. Appointed assistant surgeon from December 26, 1900.

SMITH, R. K., Passed Assistant Surgeon. Detached from the *Pensacola* and ordered to the *Wisconsin*.

STONE, M. V., Assistant Surgeon. Detached from the *Solace* and ordered to the *Isla de Luzon*.

Army Intelligence:

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from January 12 to January 26, 1901:

BISPHAM, WILLIAM N., First Lieutenant and Assistant Surgeon, United States Army, is relieved from duty at Columbia Barracks, Cuba, and will proceed to Vedado, Havana, for duty with Batteries Nos. 3 and 4, and the regimental hospital, relieving P. C. FIELD, Acting Assistant Surgeon, who will proceed to Columbia Barracks, Cuba, for duty.

BUCK, CARROLL D., Acting Assistant Surgeon, United States Army, will proceed to the Presidio of San Francisco for temporary duty, awaiting transportation to the Philippine Islands.

CARR, LAWRENCE C., Major and Surgeon, United States Volunteers, will, upon the expiration of the leave of absence granted him, proceed to Havana for duty.

REED, WALTER, Major and Surgeon, United States Army, will, upon the adjournment of the Pan-American Medical Congress at Havana, proceed to Washington for the purpose of continuing his investigation at the Army Medical Museum, with reference to the cause and prevention of yellow fever.

Marine-Hospital Service Health Reports:

The following cases of small-pox, yellow fever, cholera, and plague, were reported to the surgeon-general during the week ending January 26, 1901:

Small-pox—United States.

Washington, District of Co-		
lumbia.....	Jan. 12-19.....	2 cases.
Jacksonville, Florida.....	Jan. 12-19.....	7 cases.
Cairo, Illinois.....	Jan. 5-19.....	5 cases.
Chicago, Illinois.....	Jan. 12-19.....	12 cases.
Wichita, Kansas.....	Jan. 12-19.....	6 cases.
Lexington, Kentucky.....	Jan. 12-19.....	2 cases.
Loulsville, Kentucky.....	Jan. 4-18.....	1 case. 1 death.
New Orleans, Louisiana.....	Jan. 12-19.....	7 cases. 2 deaths.
Shreveport, Louisiana.....	Jan. 12-19.....	5 cases.
Lawrence, Massachusetts.....	Jan. 12-19.....	1 case.
Minneapolis, Minnesota.....	Jan. 12-19.....	11 cases.
St. Paul, Minnesota.....	Jan. 5-12.....	8 cases.
Omaha, Nebraska.....	Jan. 8-15.....	7 cases.
Manchester, New Hampshire.....	Jan. 12-19.....	39 cases.
Fort Stanton, New Mexico.....	Jan. 14.....	1 case.
New York, New York.....	Jan. 12-19.....	9 cases. 5 deaths.
Utica, New York.....	Jan. 12-19.....	1 case.
Cincinnati, Ohio.....	Jan. 12-18.....	3 cases.
Cleveland, Ohio.....	Jan. 12-19.....	57 cases. 1 death.
Sixteen Counties, Oklahoma.....	Jan. 11.....	289 cases.
erie, Pennsylvania.....	Jan. 12-19.....	1 case.
Pittsburgh, Pennsylvania.....	Jan. 12-19.....	3 cases.
Memphis, Tennessee.....	Jan. 12-19.....	6 cases.
Houston, Texas.....	Jan. 12-19.....	44 cases.
Salt Lake City, Utah.....	Jan. 12-19.....	32 cases.
Green Bay, Wisconsin.....	Jan. 13-20.....	1 case.

Small-pox—Foreign.

Liege, Belgium.....	Dec. 15-22.....	1 case.
Pernambuco, Brazil.....	Dec. 8-15.....	34 deaths.
Alexandria, Egypt.....	Dec. 17-24.....	2 cases. 2 deaths.
Leeds, England.....	Jan. 5-12.....	1 case.
London, England.....	Dec. 29-Jan. 5..	1 case.
Paris, France.....	Dec. 29-Jan. 5..	6 cases.
Bombay, Indla.....	Dec. 18-25.....	1 death.
Vera Cruz, Mexico.....	Dec. 29-Jan. 5..	3 deaths.
Edinburgh, Scotland.....	Dec. 29-Jan. 5..	1 case.
Glasgow, Scotland.....	Jan. 4-11.....	66 cases. 3 deaths.
Leith, Scotland.....	Dec. 29-Jan. 5..	1 case.
Singapore, Straits Settlements.....	Dec. 1-18.....	2 deaths.

Yellow Fever.

Cartagena, Colombia.....	Jan. 1-7.....	2 cases.
Cienfuegos, Cuba.....	Jan. 14.....	1 case.
Havana, Cuba.....	Jan. 5-12.....	2 deaths.
Vera Cruz, Mexico.....	Dec. 29-Jan. 5..	1 death.

Cholera.

Bombay, India.....	Dec. 18-25.....	4 deaths.
Singapore, Straits Settlements.....	Dec. 1-18.....	58 deaths.

Plague.

Bombay, India.....	Dec. 18-25.....	118 deaths.
Hull, England.....	Jan. 19.....	5 deaths on ss.
		Friary.
Tsarevsk District, Russia.....	Jan. 5.....	19 cases. 15 deaths.

Marine-Hospital Service:

Official List of the Changes of Stations and Duties of Commissioned and Non-commissioned Officers of the United States Marine Hospital Service for the Seven Days ending January 24, 1901:

BEAN, L. C., Acting Assistant Surgeon. Granted leave of absence for two days from January 18th.

CRAIG, R. C., Acting Assistant Surgeon. Granted seven days' extension of leave of absence.

PURVIANCE, GEORGE, Surgeon. Granted leave of absence for two days.

WILLIAMS, L. L., Surgeon. Granted leave of absence for three days.

Changes of Address.—Dr. Alfred W. Herzog, to No. 154 East Thirtieth street, New York; Dr. Charles E. Perkins, to Chicago, Ohio.

Illegal Medical Practice.—Louis Grojinsky and Gustav Greenbaum were held in bail of \$200 each on January 28th at the Essex Market Police Court for practising as physicians at 5 Willet Street without being licensed.

The Young Men's Christian Association as a Hospital Organizer.—The West Albany railroad branch of this institution has established at Albany an emergency hospital fitted with all necessary appliances for prompt treatment of injuries.

Omega Upsilon Phi Fraternity.—This fraternity has just organized two new chapters, one at the University of Colorado and the other a graduate chapter in New York City, under the name of the Henry C. Coe chapter, in honor of Professor Coe.

Registrations in Wisconsin.—The report of the Wisconsin board of medical examiners for the past two years shows that the total receipts of the board for that period were \$8,772, and the expenses \$7,909. There were 1,260 registrations during that period.

A Universal Practice Law.—Among the bills recently introduced into the assembly at Albany was one by Mr. Adler, authorizing the regents to admit to practice physicians heretofore admitted by State examining boards in other States of the United States.

Decrease in the Number of Medical Students in Europe.—The number of medical students in the universities has been decreasing, not only in Russia, but also in France and Germany. Instead of the usual total of from 8,000 to 8,500 students in the German medical schools, the total number of medical students in Germany this year is 7,518.

The New York State Medical Society, at the meeting held this week in Albany, elected the following officers: President, Dr. Henry M. Elsner, of Syracuse; vice-president, Dr. Louis L. Lovehart, of Hempstead; secretary, Dr. C. F. Cuirts, of Albany; treasurer, Dr. O. D. Bull, of Albany.

The Grand Jury Presentment Regarding Bellevue.—The grand jury made a presentment on Thursday recommending the discharge of Dr. J. W. Moore, Superintendent O'Rourke, and his assistant, M. J. Reckard, from Bellevue Hospital, declaring that the medical board had encroached upon the prerogatives of the commissioner of charities, and that the medical board is directly and absolutely responsible for the administration of Bellevue.

An X-ray Apparatus for Bellevue.—A lady, whose name is not made public, has presented the New York University and Bellevue Hospital Medical School with an x-ray apparatus of the value of \$1,500.

Medical Students to be Furnished with Cadavers.—A bill has been introduced by Senator Stewart into the senate allowing the Cornell medical colleges at Ithaca and New York City to have the unclaimed cadavers in public institutions in the counties where located and immediately adjoining.

The Mortality of San Francisco.—Six hundred and eight deaths occurred in San Francisco during December last, a greater number, it is said, than in any previous month since health records have been kept. Three quarters of the deaths are said to have been due to grippe and its complications.

Fifty Years an Alumnus.—Dr. Henry M. Baird, of Yonkers, will be the guest of honor at the annual dinner of the Alumni Association of the New York University, at the Hotel Savoy, February 7th. A loving eup will be given to Dr. Baird to commemorate his fifty years as an alumnus. Dr. Baird has been for many years a professor of the New York University.

School Vaccination in Buffalo.—Dr. Walter D. Greene, the assistant health officer of Buffalo, has arranged a tour of the parochial schools to vaccinate all scholars who cannot show a certificate of vaccination within the preceding five years. Time to comply with this requirement by those desirous of choosing their own physician will be given up to February 11th.

A Proposed "Elective Course" for Medical Schools.—President William R. Harper, of the University of Chicago, at the quarterly convocation of Rush Medical College, recently proposed a new method of instruction in medical and other professional schools. The plan suggests an "elective course" in which the students choose not alone their subjects, but their professors.

The Division of Fees Discussed in Chicago.—At a recent meeting of the Chicago Medical Society resolutions were offered condemning the giving of commissions or a part of the fees by physicians or surgeons to any other person. The resolutions were referred to a committee consisting of Dr. James H. Stowell, Dr. N. S. Davis, Sr., Dr. Frank Billings, and Dr. John B. Murphy.

To Stop the Spread of Bubonic Plague.—State Health Officer W. F. Blunt, of Austin, Texas, has instructed the quarantine inspectors at all western border places of the State to exercise extra vigilance against the admission of all persons from San Francisco and Bakersfield, Cal. This order is due to the alleged appearance of additional cases of bubonic plague in those places.

Two Members of a Yellow Fever Commission Contract the Disease.—Dr. Meyers, a member of the British commission sent from Liverpool to study yellow fever at Para, Brazil, died on January 21st as a result of yellow fever contracted while making an autopsy on a yellow fever victim. Dr. Duerhase, another member of the commission, is also reported as being seriously ill with the disease.

Dr. Novy to Study the Plague Situation at San Francisco.—Dr. Frederick G. Novy, of the University of Michigan, has been commissioned by the United States government to make a thorough study of the conditions existing at San Francisco with a view to determining as to the possibility of the introduction of the bubonic plague through that port.

Hazing at a Medical College.—A complaint has been lodged by a Turkish student of the Philadelphia Medical Chirurgical College that he had been hazed and, among other indignities, shorn of his moustache. The case will be inquired into by the faculty and, if substantiated, the offenders will be punished. This course will, we think, undoubtedly meet with the general approval of the medical profession.

Clinical Lectures on Orthopædic Surgery.—The trustees of the New York Orthopædic Dispensary and Hospital announce that the surgeon-in-chief, Dr. Russell A. Hibbs, will give a course of clinical lectures on orthopædic surgery at the institution, on Monday and Thursday afternoons, at five o'clock, from January 28th to February 28th (both inclusive). The course will be free to the medical profession and students.

A Sanitarium for Consumptives.—The Mercer County (N. J.) Medical Society has prepared a bill, which will be introduced by Senator Hutchinson in the Trenton legislature, providing for the establishment of a sanitarium for persons afflicted with consumption. An appropriation of \$50,000 for that purpose will be asked from the State. The bill specifies that no person shall be refused admission to the sanitarium because of his inability to pay.

A Physician's License Revoked for Advertising.—A physician of St. Paul, Minn., has had his license revoked by the State board of medical examiners as a penalty for unprofessional advertising. The courts being without jurisdiction, an attempt is to be made to obtain the Governor's interference. It would be a good thing if medical boards throughout the country would exercise themselves in repressing unprofessional conduct to the fullest extent of their powers.

Exterminating the Cuban Mosquito.—A war of extermination has been declared on the Cuban mosquito, which is charged with conveying yellow fever germs. Forty sanitary inspectors will make a thorough inspection of their districts and report all stagnant waters where mosquitoes might breed. Twice a month petroleum will be thrown upon the water which cannot be drained off, in order to kill the embryo mosquitoes. The department will also attempt to kill all mosquitoes in houses where cases of yellow fever appear.

Not Recognized as a Physician, "Dr." Cleveland Loses his Suit.—Dr. A. B. Cleveland, of Anthony, Kan., who recently sued the estate of A. R. Morrison for \$3,050 for services rendered before the death of the deceased, lost his case in the probate court recently. Judge Musser rendered his decision on the fact that Mr. Cleveland has no diploma from a medical school, nor is a member of any medical society. Under the laws of the State he is not recognized as a physician, and is therefore not entitled to collect any amount for services rendered.

Aged Doctor Acquitted of Murder.—Dr. W. W. Dickey, of Bluefield, W. Va., has been acquitted of the murder of Miss Maggie Calfree. Dr. Dickey is nearing his sixtieth year and is one of the most prominent physicians in the southern portion of the State. The trial lasted for a week and more than forty witnesses were examined on each side. When the verdict was rendered, cheers went up in the court room and the aged doctor broke down and wept like a child.

Active Steps Taken toward Abating the Spitting Nuisance.—The board of health of the city of New York has directed notices to be posted in all public places to the effect that spitting on the floors of cars and ferry-boats is punishable by a fine of \$500 or imprisonment, or both, and it is asserted that the law against the spitting nuisance will be vigorously enforced. This action, following as it does closely upon the conviction and punishment of a man for spitting on the floor of an elevated car, will probably be received with some respect by the traveling public.

A Royal Commission on the Beer Poisoning Epidemic has been appointed in England to collate data bearing upon the widespread occurrence of arsenical poisoning that has recently come to light. The commission is instructed to inquire as to whether any exceptional number of cases of illness and death observed has been due to arsenic in beer or in other articles of food or drink. In commenting upon this, the *Lancet* says that the appointment of the commission is wholly unnecessary, and is calculated to defeat the object aimed at, for the reason that the government already has ample evidence upon which to act, and act promptly; whereas the commission will require a long time for the collation of testimony and the preparation of a report, thus entailing great and unnecessary delay in action.

The Late Dr. Frank C. Merriam.—The Society of the Alumni of the City Hospital at their last meeting adopted the following preamble and resolutions on the death of their fellow member, Dr. Frank C. Merriam:

In the death of Dr. Merriam we lose an esteemed and valued friend, associated with us in the membership of our society for nearly its entire existence; and we desire to acknowledge the mutual friendship and helpfulness we have enjoyed from these years of association. It is, therefore,

Resolved, That we express our sincere and heartfelt sorrow at his death, and that our deepest sympathy be tendered to the doctor's bereaved family. Further be it

Resolved, That a copy of these resolutions be sent to the family and to the medical journals, and be entered upon the minutes of our society.

ADOLPH RUPP, M. D.,

A. T. MUZZY, M. D.,

WM. L. STOWELL, M. D.

Medical Supplies for the Philippines.—Arrangements have been made at the war department to send the transport *Wright* from New York to the Philippines by the Suez canal route, with a corps of officers of the medical department and a cargo of medicines and medical supplies for the benefit of the troops in the Philippines. First Lieutenant Henry A. Webber, assistant surgeon, has been detailed as acting assistant quartermaster and as acting commissary of subsistence on the *Wright*. Orders have been issued for the following-

named assistant surgeons to proceed to the Philippines by that transport for assignment to duty: H. D. Belt, at New York City; T. F. Goulding, at Boston, Mass.; F. E. Thompson, at Cleveland, Ohio, and A. N. Wilkins, at Delta, Ohio.

The Rome Medical Society held its annual meeting at Rome, N. Y., on January 15th, when the following officers were elected: President, Dr. A. A. Gillette; vice-president, Dr. H. J. Teller; secretary, Dr. T. P. Scully; treasurer, Dr. G. N. Lehr.

Georgia Medical Society.—The Georgia Medical Society held its annual meeting at Savannah, Ga., on January 9th, and elected the following officers: President, Dr. T. P. Waring; vice-president, Dr. J. A. Crowther; recording secretary, Dr. C. B. Lanneau; corresponding secretary, Dr. A. A. Morrison; librarian, Dr. J. G. Van-Marter, Jr.; treasurer, Dr. J. S. Howkins.

The Society of Medical Jurisprudence.—The one hundred and fifty-fifth regular meeting was held on Monday evening, January 14, 1901, at 8 P. M., at the Academy of Medicine, in New York City. The paper of the evening was on *The Legal and Medical Aspect of Food Adulteration*, by Professor H. W. Wiley, chief of the division of chemistry, U. S. Department of Agriculture, Washington, D. C.

The Toledo Medical Association has elected the following officers for the ensuing year: President, Dr. W. H. Fisher; vice-president, Dr. John North; recording secretary, Dr. Charles P. Wagar; corresponding secretary, Dr. A. C. Schnetzler; treasurer, Dr. F. E. Klausner. The election, which was held on January 11th, was followed by a banquet at the St. Charles Hotel.

Kings County Medical Society.—At the recent annual meeting of the Kings County Medical Society the following officers for the year were elected: Dr. William Browning, president; Dr. Henry A. Fairbain, vice-president; Dr. David A. Myerle, secretary; Dr. William Hubbard, associate secretary; Dr. O. A. Gordon, treasurer; Dr. John R. Steivers, associate treasurer; Dr. J. M. Winfield, librarian. Dr. George R. Fowler was elected a member of the board of trustees.

Albany Medical Society.—At the regular meeting of the Medical Society of the County of Albany, on January 16th, the following papers were read: *The Intestinal Form of Influenza*, by Dr. S. B. Ward; *The Pulmonary Form of Influenza*, by Dr. Howard Van Rensselaer. The next meeting will be held on February 13th, when the following papers will be presented: *The Diagnosis of Cancer of the Stomach*, by Dr. Andrew MacFarlane; *Surgical Intervention in Cancer of the Stomach*, by Dr. Willis G. MacDonald.

Foreign Association Notes.—The German Society of Physicians, which has a membership of about 16,000, contemplates making some radical changes in its organization. One of these is to pay a salary to the president, and to make him at the same time editor of the official organ of the society, the *Aerztische vereinsblatt*.—The British congress on tuberculosis will be opened on July 22d by the Prince of Wales. The congress will be divided into four sections: Pathology, medicine, public medicine, and veterinary medicine. The address of the general secretary is 20 Hanover Square, London, W.

A Pacific Medical Association.—According to press dispatches a Pacific medical association is to be organized, with San Francisco as the centre of a western medical field embracing Washington, Oregon, Idaho, Montana, Utah, Nevada, Arizona, California, Alaska, British Columbia, the Hawaiian Islands, the Philippines and other islands of the Pacific, the western part of Mexico and of the Central American republics, and possibly the empire of Japan. A preliminary meeting of prominent physicians interested was held recently.

The Medical Society of City Hospital Alumni, St. Louis.—At the annual meeting, on December 20, 1900, the following officers were elected for the ensuing year: President, Dr. Norvelle Wallace Sharpe; vice-president, Dr. Francis L. Reder; secretary, Dr. John Green, Jr.; treasurer, Dr. Horace W. Soper.

At a special meeting, on Thursday evening, the 31st ult., Mr. Charles F. Longfellow, superintendent of public buildings, exhibited the plans for the buildings of the new City Hospital.

The New York Academy of Medicine.—At the next stated meeting, on Thursday, February 7th, the order for the evening is as follows: Presentation of a bust of the late Dr. Horace Green; the reading of the following papers on conservative operations upon the uterine appendages: Their Technique, by Dr. J. Riddle Goffe; The Significance and Importance of such Conservative Operations, by Dr. William M. Polk; The Immediate and Remote Results in One Hundred Cases of these Operations, by Dr. W. L. Burrage, of Boston; and An Experience in One Hundred and Twenty-five Similar Cases, by Dr. A. P. Dudley. Dr. Coe, Dr. Boldt, Dr. Wiggin, and Dr. Grandin will take part.

A Hospital Wins a Damage Case.—In the Supreme Court at Buffalo recently Justice Childs directed a nonsuit in the action brought by Mrs. Catherine K. Wiles against the German Deaconesses' Home and Hospital to recover \$20,000 damages. The defendant corporation showed that the hospital attendants were not responsible in any way for burns received by Mrs. Wiles in taking a steam bath.

The Bell Bill Arouses Opposition.—The measure introduced in the assembly of the State of New York by Mr. Bell with a view to preventing the practice of Christian Science is arousing very active opposition on the part of a variety of interests which would be affected, though the bill may not have been intended to do so. The proprietary medicine interests would be seriously affected, as would also the retail drug trade and dealers in orthopædic supplies. All three of these interests actively oppose the passage of the measure. Dr. Frank Van Fleet, chairman of the committee on legislation of the Medical Society of the State of New York, which has drafted the proposed amendment to the Public Health law, said recently, in speaking of the amendment: "The object of the proposed amendment is to compel every physician to comply with the laws. If educated men are compelled to comply with the laws, and if uneducated men can evade them by posing as Christian Scientists, osteopaths, hydropaths, etc., then the present law is not an incentive for men to make themselves competent. Yet the medical laws are enacted to protect people from incompetent practitioners. Any one who is registered in the county clerk's office is competent, and the

fact that he is allowed to register is a guarantee of his competency by the State. The object of the present amendment is not to discriminate, but to compel every one who wishes to treat disease to register. The present law does not protect the community."

Foreign News Notes.—The Eighth International Congress on Inebriety will be held in Vienna from the 9th to the 14th of April. The chairman of the committee on organization is Professor Max Gruber. Full information concerning the programme can be obtained from the secretary at No. 17 Schwartz-spanier Strasse IX, Vienna.—The essay upon tuberculosis by Dr. S. A. Knopf, of New York City, which was awarded the prize of 4,000 marks at the recent Congress on Tuberculosis, has been printed in pamphlet form by the central committee for the erection of sanitariums for consumptives in Germany, and will be furnished by this committee at a very low rate to encourage its general distribution. With a view to encouraging the wider dissemination of the essay, full permission is given to any one to reprint or to translate the essay.—The Spanish pathologist, Dr. Ramon y Cajal, whose original work upon the anatomy of the nervous system has attracted the attention of the whole world, has heretofore received but very little attention in his native land. It was not until after he had been awarded the prize of 5,000 francs by the City of Moscow at the recent International Medical Congress at Paris for his work upon the neurone that the government gave him a salaried appointment. Now a subscription is being taken up in Spain with the purpose of founding a laboratory in which he can prosecute his studies.—Professor Ernst Haeckel has received from the Royal Society of London the Darwin Medal for his long and valuable labors in the field of zoology.—A young Italian physician of Rio Grande du Sol, by the name of Angelio Bellinghazi, has been awarded a portion of the \$100,000 prize offered by the Mexican government for the discovery of a remedy for yellow fever.—The law regarding tuberculosis which went into effect in Norway on January 1st is so stringent that it has aroused a most vigorous and general protest. Under the law all persons affected with tuberculosis are required to take up their residence in a sanitarium devoted to the treatment of this disease. This is impracticable, since there are not enough institutions of this character in the kingdom to furnish the necessary accommodations.—The physicians of Vienna have become very much exercised over the growth of the illegitimate practice of medicine by charlatans of various kinds, and active steps are being taken to diminish the evil.—The twenty-second congress of balneology will be held in Berlin from the 7th to the 12th of March. Dr. Liebreich is president of the congress, and thirty-seven essays have already been promised from leading specialists in Germany.—In Budapesth a decree has been issued requiring the disinfection of rooms in which tuberculosis patients have died.—A chair of colonial medicine has recently been established in the University of Paris which will give particular attention to the study of tropical diseases.

Typhoid Fever.—The statistics recently presented by the annual report of Dr. Matson, bacteriologist of the Pittsburgh board of health, show that one per cent. of the population of that city suffered from typhoid during the year 1900. The deaths from typhoid numbered 465, the largest number ever recorded in a single year.

Diphtheria.—According to the annual report of Dr. Matson, of the Pittsburgh health board, the mortality from diphtheria in that city has largely diminished. The reduction is attributed to the use of antitoxine.—Diphtheria has been reported at East Tawas, Mich., and one family quarantined.

Small-pox.—Reports from most of the districts afflicted are to the effect that the disease is gradually subsiding in virulence. In this city, President Murphy, of the Health Department, has appointed fifty additional deputy sanitary inspectors to assist in the work of vaccination.—A bill is to be introduced in the Colorado legislature to provide for a \$4,000 appropriation with an emergency clause attached, the amount to be expended by the State board of health in paying for the employment of small-pox inspectors to aid in suppressing the spread of the disease.—Dr. M. J. Rodermund, of Appleton, Wis., who smeared himself with small-pox virus and then rubbed against and touched as many persons as possible to prove his theory that no disease is contagious, was quarantined in his house, with his family, by two policemen, at latest accounts. He tried to retain a lawyer, but no lawyer would take his case. If other cases of small-pox break out it is feared violence will be done him. Dr. Rodermund made this statement: "I shall exhaust every legal means to obtain my release from quarantine. Such means failing, I shall free myself at any cost. It was not my intention to alarm the public. I would have kept silence until a month from now, when I would have made known my experiment." Later he escaped, and was arrested at Terre Haute, Ind. His sanity will be inquired into.—Frank Lemlich, a resident of the Bronx, was recently held in \$500 for concealing the fact that his child had small-pox. The mother has fled with the infant and has not been apprehended.—Small-pox has been reported at Houston, Wis., where the health officers stopped a dance that was in progress and placed the residents of the hotel where the case was discovered in quarantine.—At Angus, Neb., three families have provided ten cases of small-pox.—Bellevue, Neb., is now said to be free from the disease.—Twelve cases have been reported at Crestline, O., but owing to trouble between the members of the health board no quarantine had been established up to January 24th.—Among other places reporting the disease are Chagrin Falls, O.; Oshkosh, Wis.; Minnesota City, Minn.; Lansing, Mich.; Albany, N. Y.; Bryant, Mich., in a lumber camp (eleven cases); White River, Ontario; Austin, Ill., and Columbus, Miss.

A Marine Hospital for New York.—Secretary Gage has sent to Congress a request by the supervising architect of the Treasury Department that three acres of flats in New York harbor adjacent to Ellis Island be reclaimed, at a cost of \$100,000, the material excavated from the new Custom House site to be utilized for the purpose. The reclaimed land is to be used for a marine hospital.

Visiting Staff of Cooper Hospital at Camden, N. J.—At the annual meeting of the board of managers of Cooper Hospital, Camden, N. J., the following-named were elected as the visiting staff of physicians and surgeons of that institution for the ensuing year: Medical, Dr. H. Genet Taylor, chairman and secretary; Dr. W. A. Davis, Dr. E. L. B. Godfrey, Dr. W. R. Powell; surgical, Dr. Daniel Stroock, Dr. Joseph L. Nicholson, Dr. Paul M. Mceray, Dr. E. A. Y. Schellenger; ophthal-

mologist, Dr. William R. Powell; gynecologists, Dr. Dowling Benjamin and Dr. J. S. Baer; laryngologist, Dr. Ernest S. Ramsdell; pathologist, Dr. Walter S. Bray.

The President of the New York State Medical Society on Hospitals and Malpractice.—Dr. A. M. Phelps, in his presidential address at the ninety-fifth annual meeting of the society, at Albany, on January 29th, attacked the bill of Senator Grady which provides that hospitals shall not be liable for malpractice cases. He said:

"Recent decisions in cases of malpractice suits brought against hospitals have been decided against the latter on the ground that any hospital that treats patients for pay and has private rooms where private patients are treated, is the principal defendant. This is right. The surgeon is simply the agent of the hospital, and very grave injustice has been done to faithful surgeons and doctors on account of the neglect of some of the internes or nurses, and to my knowledge such men have been prosecuted for malpractice. The hospitals have turned their backs on them, and they have been mulcted in large sums. Now, this bill introduced by Senator Grady is vicious and should be defeated, and the chair recommends that this society should pass a resolution asking the legislature to defeat it, and that, in the event of its passage, the Governor veto it. It is to be hoped that the legislative committee will take the matter in hand and see that this piece of vicious legislation is defeated."

The following resolution was adopted:

Resolved, That the Medical Society of the State of New York heartily indorses the report of the tenement house committee appointed by Governor Roosevelt, and urgently requests the legislature to adopt its recommendations regarding the improved housing of the poor and the further control of the spread of infectious diseases.

Hospital Buildings and Endowments.—The new annex to St. Mary's Hospital, Philadelphia, which has cost \$75,000, is almost ready for occupancy. It has a frontage of ninety feet and a depth of one hundred feet. The building is four stories in height and is of brick, faced with drab Pompeian brick, with trimmings of Indiana limestone. It is of fireproof construction, with steel beams and tiled floors. There is an electric elevator, and three separate stairways from the first floor to the fourth.—By the will of the late Albert E. Kent, of Chicago, the sum of \$50,000 is bequeathed toward the completion and equipment of the Kent Laboratory, which was established by the testator.—The following officers and directors were elected at the annual meeting of the Mount Sinai Hospital, New York, on January 27th: President, Isaac Wallach; vice-president, Isaac Stern; treasurer, E. Asiel; secretary, Louis M. Josephthal; directors, for the term of four years, Isaac Blumenthal, Louis Stix, Isaac N. Heidelberg, Adolph Herrmann, and David Wile. A supplementary report presented by the building committee announced that the awards for the new buildings at One Hundred and First Street and Madison Avenue had been made, and that the work would go on speedily. Of the \$1,650,000 required, all but \$300,000 had been secured up to two weeks ago. Since that time the board of directors has subscribed \$75,000, leaving only \$225,000 lacking, which, it is thought, will be readily secured. The total number of patients treated

during the year was 3,352. Of that number 1,963 were discharged cured. Accident cases treated, not included in the above, were 592. The percentage of patients treated gratuitously was 80.60. In the dispensary there were 86,431 consultations, and 77,663 prescriptions were filled. Two hundred and fifty-three patients were treated in the outdoor department. The total expenses of the hospital and dispensary were \$136,271.31.—At the recent annual meeting of the Willard Hospital of Bedford, Mass., the former board of officers was re-elected, as follows: President, Rev. Edward E. Hale; vice-presidents, John Gilchrist and Myron T. Pritchard; treasurer, Edward May; secretary, Dr. S. B. Eliot.—At the annual meeting of the Salem, Mass., hospital corporation, the old board of trustees was re-elected. During the past year 411 patients were admitted to the hospital (a falling off in the total number), of whom 200 were medical and 211 surgical cases.—The Freedmen's Hospital at Washington, D. C., has become so crowded that it has become necessary to deny admission to applicants.—At the request of the Michigan board of health, a bill has been introduced in the legislature appropriating \$60,000 for the establishment of the Michigan State Hospital for Consumptives, and \$4,000, or a sufficient amount, to pay the running expenses. The establishment of the institution is intrusted to the State board of health, after which it passes to the control of the regents of the University of Michigan. The board of health is empowered to select a site, appoint an architect, and superintend the erection of the building. Briefly stated, the bill gives the object of the institution as the treatment of consumption and the proper training of medical students. The regents are empowered to appoint a medical and surgical staff of five members, one of whom shall be a professor of hygiene and bacteriology, and to fix their salaries. Residents of the State will be received free of charge, and poor persons will be supplied with clothing, etc., by the county in which they reside. Provision is also made for receiving non-residents, the charges to be fixed by the regents.—At the recent annual meeting of the Pacific Christian Hospital, of San Francisco, a building committee was appointed with a view to building during the year. The expenses of the institution for the past year amounted to just \$12,000.—The Navy Department has proposed that the city permit the department to use the northern end of the island as a parade ground and park. The insane pavilion is to be vacated. The project has not met with the approval of the local authorities.

Births, Marriages, and Deaths.

Born.

McCULLOCK.—In Waco, Texas, on Sunday, December 23, 1900, to Dr. C. C. McCulloch, United States Army, and Mrs. McCulloch, a son.

Married.

COOLIDGE—REYNOLDS.—In Boston, on Wednesday, January 17th, Mr. Julian Lowell Coolidge and Miss Theresa Reynolds, daughter of Dr. John Phillips Reynolds.

DUFFY—NOLAN.—In Washington, on Wednesday, January 23d, Dr. William F. Duffy, of Bristol, Rhode Island, and Miss Rose H. Nolan.

FISHER—SWOPE.—In Lebanon, Pennsylvania, on Thursday, January 24th, Dr. George S. Fisher and Miss Anna A. Swope.

GOLDSTEIN—SCHWARZSCHILD.—In New York, on Sunday, January 20th, Dr. Aaronson Goldstein and Miss Jeannette Schwarzschild.

KETCHUM—MYERS.—In Lonaconing, Maryland, on Wednesday, January 23d, Dr. Frank Gray Ketchum, of New York, and Miss May Myers.

MCMAMARA—GALLAGHER.—In New York, on Wednesday, January 23d, Dr. Thomas C. McNamara, of Hoboken, New Jersey, and Miss Minnie Eloise Gallagher.

RAMSEY—BALL.—In Waco, Texas, on Wednesday, January 16th, Dr. W. H. Ramsey, of St. Louis, and Miss Edna Ball.

WISTER—DUNN.—In Germantown, Pennsylvania, on Wednesday, January 23d, Dr. James Wilson Wister and Miss Elizabeth Bayard Dunn.

Died.

BURDEN.—In New York, on Sunday, January 26th, Dr. Charles Burden.

CHRISTOPHER.—In St. Joseph, Missouri, on Monday, January 21st, Dr. Herman Christopher, aged eighty-five years.

HERRICK.—In Cleveland, on Monday, January 28th, Dr. Henry J. Herrick.

MCCARTHY.—In Boston, on Monday, January 21st, Dr. Frederick J. McCarthy, of Malden, Massachusetts, in the twenty-fifth year of his age.

NELSON.—In Newmarket, New Jersey, on Sunday, January 27th, Dr. Frederick S. Nelson, aged twenty-seven years.

NOTT.—In Rexford Flats, Saratoga County, New York, on Tuesday, January 22d, Dr. Eliphalet Nott, aged sixty-seven years.

PARKER.—In Richmond, Virginia, on Thursday, January 24th, Dr. William W. Parker, in the twenty-fourth year of his age.

PARKHURST.—In Frankfort, New York, on Tuesday, January 22d, Dr. William H. H. Parkhurst, aged eighty-eight years.

PURDY.—In Chicago, on Sunday, January 20th, Dr. Charles Wesley Purdy, in the fifty-fifth year of his age.

RUNDLE.—In Passaic, New Jersey, on Monday, January 21st, Dr. George L. Rundle, in the thirty-first year of his age.

SCHUPPERT.—In New Orleans, on Wednesday, January 16th, Dr. Charles E. Schuppert, in the forty-fourth year of his age.

STICKEL.—In Harrisburg, Pennsylvania, on Thursday, January 24th, Dr. Henry L. Stickel, formerly of the United States Army, in the forty-eighth year of his age.

STRONACH.—In Belleville, New Jersey, on Tuesday, January 22d, Dr. James Watson Stronach, of New York, in the sixty-first year of his age.

THOMPSON.—In Amherst, Virginia, on Wednesday, January 23d, Dr. John Thompson, aged sixty-two years.

Obituaries.

CHARLES WESLEY PURDY, M. D., LL. D.

DR. PURDY died at his home in Chicago on January 20th. He was born in 1846 at Kingston, Ontario, and received his medical education at the Queen's University, where he graduated with high honors. For a short time he practised in his native town, and then came to Chicago, in which city he was actively engaged in practice up to the time of his recent illness, which terminated fatally. He made a close study of renal diseases, upon which subject he published, among other things, a work on Bright's Disease and Allied Affections of the Kidneys, one on Practical Ureanalysis and Urinary Diagnosis, the fifth edition of which was reviewed in the *New York Medical Journal* for November 24, 1900, as well as numerous contributions to the medical journals, including one in this journal so late as June, 1899. Dr. Purdy was also the recipient of honors from the Royal College of Physicians and Surgeons of Canada, and a year or two ago was honored by his Alma Mater with the degree of LL. D. (*honoris causa*). He will be much missed by many friends, both in and out of the medical profession.

Pith of Current Literature.

Boston Medical and Surgical Journal, January 24, 1901.

A Short Abstract of the Early History of Medicine in Massachusetts to the Year 1800. By Dr. Elbridge G. Cutler.—This article points out: (1) the prominent position which Massachusetts held in the advancement of medicine in the early days, and (2) the close relation between the physician and the clergyman, the two professions being often united in one individual.

The Great Toe (Babinski) Phenomenon: A Contribution to the Study of the Normal Plantar Reflex Based on the Observation of One Hundred and Fifty-six Healthy Individuals. By Dr. Morton Prince.—The author's belief is that the frequency of the plantar (spinal) reflex, so far as it concerns the toes, has been exaggerated owing to several sources of fallacy being overlooked, namely: (1) mistaking the cerebral for the spinal reflex; (2) in stroking the sole it is not difficult by moderate pressure over the first phalanges to cause a purely mechanical flexion of the toe; (3) if the stroke is made from the toe toward the heel, pulling on the skin, when inelastic, will do the same.

A Case of Obliteration of the Right Ureter by a Calcified Fibroid; Removal of Fibroid and Implantation of the Ureter into the Bladder; Recovery. By Dr. Maurice H. Richardson.—The author recommends that the dissection of the deep pelvis—like that of the deep neck—should be made in the full light of day, where every structure can be recognized as the dissection proceeds. The cases in which this deliberate dissection cannot be made, or in which the structures are too changed for recognition, are extremely infrequent.

A Case of Vesical Implantation of the Ureter by Dudley's Forceps Method after the Failure of Several Plastics. By Dr. Edward Reynolds.—The chief risk of failure in ureterovesical implantation is always from the slipping away of the ureter, owing to the thinness of its walls and the consequent difficulty in its being securely sutured to the bladder. This danger is entirely obviated by the Dudley method of securing the ureter and bladder together by forceps. The presence of the forceps must at the same time direct the stream of urine into the bladder, and in the author's case its presence in the bladder caused no discomfort.

Pregnancy Following the Removal of Both Ovaries and Tubes. By Dr. M. A. Morris.—The author regrets that the parts removed had not been subjected to a microscopic examination. He believes that there may have been a third ovary, as supernumerary ovaries have been found twenty-three times in five hundred bodies by Biegel, or that there must have been a scrap of ovarian tissue left behind.

Philadelphia Medical Journal, January 26, 1901.

Two Cases of Epiplopepy in Cirrhosis of the Liver. By Dr. John B. Roberts.—Though it is too early to reach a definite conclusion as to the clinical value of epiplopepy in cirrhotic liver, the author believes that, as the operation is so comparatively trivial and the disease so intractable, a comparatively early resort to it seems justifiable. The incision should be made above the umbilicus under local anæsthesia, and the sutures should be carried through the external skin by means of a curved needle, while the forefinger of one hand within the abdomen holds the omentum against the anterior abdominal wall.

The Surgery of the Stomach. By Dr. Albert I. Bouffleur.—An interesting epitome of the characteristics, clinical history, diagnosis, and treatment of the surgical diseases of the stomach. In regard to ulcer of the stomach, the author quotes Ewald and Welch, to the effect that it occurs in fully five per cent. of mankind. He believes that gastro-enterostomy is the elective operation for ulcers with chronic hæmatemesis. In cases of acute perforation, immediate gastrorrhaphy is unquestionably demanded. The investigations of Greenough and Joslyn revealed the fact that only one half of the eighty per cent. of ulcer patients discharged from the Massachusetts General Hospital as relieved, remained well at the end of five years, which would show that permanent relief failed in sixty per cent., and that twenty per cent. of the whole number died. As an essential to successful operating, the stomach should be both empty and clean. Preliminary lavage with warm water and boric-acid solution is emphasized, and it is good practice to utilize rectal feeding *before operation* in order to accustom the rectum to its new duties and to derive the benefit of increased nourishment.

A Case of Ligature of the Innominate Artery for Aneurysm. By Dr. S. P. Delaup.—Though death occurred on the twenty-third day in this case, the author asserts that, under favorable circumstances, the operation by ligature is in certain conditions justifiable and advisable, and that, with the improvements in the physical characteristics of the ligature and in the method of its application, and also with modern aseptic methods, it may yet be followed by favorable results.

Branchial Cysts and Fistulæ. By Dr. W. M. L. Coplin.—With regard to treatment, total ablation, where possible, is the only commendable plan. Pockets that cannot be excised may be cauterized.

Retardation of Growth as a Cause of Shortening after Coxitis. By Dr. Henry Ling Taylor.—This retardation of growth is the rule after coxitis and other affections causing long periods of lameness or disability in childhood, and the amount of retardation bears a distinct relation to the amount and duration of the restraint or disability. This inhibitory effect of restraint should be considered in selecting treatment for disabling affections of the lower limbs.

A Report of a Case of Rabies. By Dr. Frederick Krauss.

Journal of the American Medical Association, January 26, 1901.

The Diagnosis of Diabetes Mellitus. By Dr. James B. Herrick.—The author calls attention to the importance, not only of diagnosing the diabetes, but also of recognizing the variety of the disease. Though the classifications are all more or less artificial, they are valuable, and if we make no sharper distinction than between mild, moderately severe, and severe types, our treatment will be far more rational and effectual, and our prognosis far nearer the truth, than if we make merely one large class including all cases of diabetes. Due consideration of the age, tendency to obesity, heredity, and of organic disease of the pancreas or nervous system as an ætiologic factor enables one to recognize the type. It is especially valuable to note the effect of the withdrawal of carbohydrates. It is not always the amount of sugar that determines the severity of the case; it is rather the amount in comparison with the amount of carbohydrates in the diet.

Diabetes Mellitus. The Mortality therefrom in the City of New York during the Period from 1889 till 1899; from the Official Records. Comments. By Dr. Heinrich Stein.

Cutaneous Diseases Accompanying Diabetes. By Dr. M. B. Hartzell.—The greater number of these diseases are of an inflammatory character, resembling in a general way the inflammatory diseases of the skin due to other causes, but also presenting certain peculiarities as to location and course, which suggest their aetiology. The local treatment is largely that of similar diseases occurring in the nondiabetic. In the inflammations so common about the genitalia, scrupulous cleanliness will go far toward a cure, or if not a cure, relief. If the parts are frequently bathed before inflammatory symptoms have actually appeared, they may be entirely prevented. However, the treatment of the underlying cause, the diabetes, is of far more importance than any local remedies.

Post-anæsthetic Paralysis. By Dr. C. C. Hersman.—Paralysis following an anæsthetic are more imagined than real, and the author has seldom seen a case of post-anæsthetic paralysis that did not clear up rapidly. Reflex paralysis may be looked upon, in this connection, as purely accidental. The peripheral palsy is the only one of importance to the anæsthetist. It is avoidable. All faulty positions should be guarded against and no long-continued pressure of any nature should be allowed. Massage, passive motion, and injections of strychnine in the region of the nerve trunk have done good. The fallacy among medical men is the belief that peripheral palsies recover soon, and, on that account, these accidents do not receive proper attention.

The Treatment of Neurasthenia. By Dr. Daniel R. Brower.—Neurasthenia is a pathological fatigue arising most frequently from gastro-intestinal intoxication. The vasomotor mechanism is the first to show the effect, and the degree of disturbance in vascular tension is a great aid in prognosis. Partial rest is necessary, and recuperation must come through digestible and assimilable diet. Electricity is of value, and sponge baths—gradually lowered to 50° F., prolonged for about one hour—are a necessary part of the treatment proposed by Dr. Weir Mitchell. The European trip has been very detrimental to several of the author's patients. No matter what special line of treatment is adopted, however, it is very important to keep the patient busy in his efforts at cure, and a daily schedule of therapeutic work should be furnished to him.

Intubation in Private Practice and its Perfection. By Dr. J. Trumpp.—Intubation is by no means more dangerous than tracheotomy and ought not be confined to hospital practice. A physician should not proceed to the operation, however, until he has had sufficient previous practice on cadavers and animals. Tubes of that size are preferable which can just pass the larynx without being forcibly pushed in. The rubber tubes of O'Dwyer are to be preferred.

Traumatism during Intubation—Its Prevention and Treatment. By Dr. Johann von Bokay.

Fracture of the Patella. By Dr. James M. Barton.—All methods of external treatment have failed. The risks of the operation are slight. Surgeons are constantly shortening the period of rest after the operation, and one of the possibilities of the future is that the patient will be permitted to move his leg as soon as the

external wound has healed. It is best to wait for eight or ten days before operating.

Growths in the Frontal Sinus. Two Cases; Operation; Recovery. By Dr. W. D. Hamilton.

Treatment of the Gastro-intestinal Symptoms in Typhoid Fever. By Dr. J. H. Anders.

The Unbroken Skin as an Absorbing Medium. By Dr. Thomas F. Reilly.—A medicinal agent, to be absorbed by the unbroken skin, must either become volatile during its application, or be incorporated in a fatty base and applied with friction. Occlusion is an absolute requirement in the case of volatile substances. Most of the absorption occurs in the crypts of the sebaceous glands. The effect is much slower, about one fourth as intense, and longer continued than when the same agent is administered by the mouth.

Idiosyncrasy as to Mercury. A Case of Erythema Mercuriale. By Dr. Albert Bernheim.

A New Objective Test for Mastoiditis, with Report of a Case. By Dr. Albert H. Andrews.

Ocular Manifestations of Diabetes Mellitus. By Dr. L. A. W. Alleman.

Some Remarks on the Plantar Reflex, with Especial Reference to the Babinski Phenomenon. By Dr. J. T. Eskridge.

Medical Record, January 26, 1901.

Early Diagnosis of Mammary Tumors. By Dr. George F. Shrady.—The strongest side of the argument for safety is the removal of all growths, whether in young or old. It is only a question of saving the breast in benign tumors, and of sacrificing the entire organ and its varied lymphatic connections in malignant ones. Even in adenomata there are the best of reasons for this course. No tumor of the breast can be considered a trivial affair. A mammary neoplasm is bad company, no matter how we argue to the contrary. There is hardly a "simple tumor," so-called, which, when discovered in the breast, may not eventually become malignant, and to take the chance of an exception to this rule one must be very sure of his ground.

Some Further Work on the Mosquito-malaria Theory, with Special Reference to Conditions around New York. By Dr. William N. Berkeley.—Of the three species of anopheles native to North America, the author has found two around New York: *Anopheles quadrimaculatus* (Wiedemann) and *Anopheles punctiformis* (Say). The anopheles was found always in buildings, oftenest on the walls and ceilings of recently used bedrooms, and far more abundantly in the foul and ill-ventilated bedrooms of the poor. The house females were usually gorged with blood, and sluggish enough to be easily caught. The author believes that the health department should require malarial cases to be reported. "It is at least as dangerous as scarlet fever, and far more of a scourge. An inspector should be sent to every infected house to instruct the people to kill all the anopheles in the house, to provide the doors and windows with screens, to isolate the patient with particular care from mosquitoes, and to cause all the standing water in the vicinity to be drained or heavily petrolized." The author believes that, by these measures, the number of local cases could be reduced by more than ninety per cent. in a year or two. The work of the Italians in this connection is referred to.

The Causation, Prevention, and Treatment of Gout. By Dr. Alexander Haig.—As regards causation, the au-

thor's position is that gout is due to poisoning by flesh and tea and similar substances, which introduce uric acid into the body in very considerable quantities. This uric acid may not only remain in the body, but may prevent the excretion of the uric acid formed in the body, and, as a result, the body becomes more or less saturated with uric acid, which may irritate its fibrous tissues or may obstruct its capillaries, causing high blood pressure and defective capillary circulation and their results. Prevention consists in removing from the diet of the young all substances which contain a notable quantity of uric acid. For treatment, two things are necessary: (1) to cut off the poisons that have been the cause of the trouble, so that introduction shall as far as possible cease; (2) to provide for the elimination of the poison already in the body. Diet meets the first indication, and one result of altering the diet will be that the body will gradually clear itself of the accumulated uric acid it contains. It is only in a few special cases that we need to use drugs at all.

The Non-myxomatous Character of Nasal Polypi. By Dr. Jonathan Wright.

Medical News, January 26, 1901.

Lakewood as a Winter Resort. By Dr. William Gray Schaffner.—Lakewood does not pretend to the dignity of a European spa. It is simply a nearby country village, pretty and attractive, dry and sunshiny, free from malaria and infections of all kinds, and so situated that outdoor life is possible nearly every day during the winter.

The Climatic Treatment of Chronic Bright's Disease. By Dr. James Tyson and Dr. T. Mellor Tyson.—Equality of temperament and diminished wind force are important factors in the climatic treatment. A hot, dry climate is more beneficial than a cold, dry climate. The direct tendency of altitude in chronic nephritis is toward its cure, but it must be remembered that most of these patients have either a failing heart or one that has already lost compensatory power. For such cases great altitudes are harmful.

Treatment of Syphilis at Hot Springs, Ark. By Dr. James T. Jelks.—Strict hygienic treatment is supplemented by the baths and drinking of the hot water. By reason of the very rapid elimination of medicines produced by the drinking and bathing, much larger doses of the required remedies may be given than are usually tolerated by the patients in their homes. Instead of twenty grains of iodide salts, three times daily, it is a common thing to give from fifty to one hundred grains at a dose. Mercury is used in such doses as the patient may need. The results of treatment are encouraging in the extreme.

Some Topographical and Climatic Features of the Florida Peninsula; with Special Reference to its Adaptiveness as a Winter Health Resort. By Dr. James K. Crook.—In cases of recurring bronchitis or winter cough, a sojourn of two or three months in Florida during the depth of the northern winter usually results in material improvement, often in a permanent removal of the *materies morbi*. A majority of cases of early phthisis prior to the formation of cavities are greatly benefited, though patients showing great debility or a severe degree of anæmia should not be sent to a southern climate. Cases of so-called fibrous phthisis or chronic interstitial pneumonia will be improved by a visit of several months. There is also a very large valetudinarian class.

The Climatology of Neurasthenia. By Dr. F. Savary Pearce.—An altitude of over two thousand feet is unsuitable for the neurasthenically disposed or convalescent patient. Any very "stimulating" climate should be avoided. Other conditions to be avoided are as follows: Districts menaced by high winds and frequent fogs; cloudy, saturated atmospheres with but slight movements of air currents, low country (sea level) with continuous, non-varying, although moderate heat, as where the effects of the Gulf Stream are strongly felt. Ideal conditions for the neurasthenic include sea air in a well-wooded country, far enough from the coast to avoid its fogs. A sea voyage is, as a rule, an excellent preliminary to other climatic measures. Provided the voyage is not stormy, it acts both psychically and physically in soothing the nervous system. The patient must have good food; without this, the desirable climatic change may be entirely defeated in its effect on the patient.

The Tonsils as Portals of Infection. By Dr. Julius Ullmann.—In an excellent article the author endeavors to show that the normal tonsil has a physiological function, probably protective to the organism. When this function is impaired, as it often is, the tonsil becomes the nidus for the growth of pathogenic organisms and the distribution of their poisonous products into the system. If the exanthemata, especially scarlatina, are of bacterial origin, the tonsil acts in part as port of entry. Acute articular rheumatism and the diseases often associated with it, are, in a great majority of cases, due to the action of attenuated bacteria, their toxins, or both, entering the general system through a diseased tonsil. Scrofulosis and tuberculosis are often connected with diseased tonsillar tissue. The tonsil is too little examined at necropsy, and much light might be shed on fevers of uncertain origins by bacteriological and histological examination of them.

Lancet, January 19, 1901.

Enlargement of the Prostate. By Dr. P. J. Freyer (*continued*).—In certain selected cases of enlargement of the prostate an operation of some kind is advisable, and in a small minority of cases it is imperative, to save the patient's life or to ameliorate his sufferings. But in the vast majority of cases the only admissible treatment is judicious and cleanly catheterism combined with careful hygienic treatment.

Where the affection is unattended by symptoms no treatment is necessary. Where decided symptoms of obstruction are present but the bladder contains no "residual" urine, the author advises the passing of a large steel dilator as far as the bladder once a week, leaving it in position for ten minutes, beginning with a No. 11, English scale, and gradually advancing to No. 15 or No. 16. This simple procedure is often most beneficial, saving off for an indefinite period the necessity for habitual catheterism. The internal administration of liquid extract of ergot at the same time is often beneficial; it seems to act by relieving congestion. When the "residual" urine amounts to three or four ounces, and there is frequent nocturnal micturition, it will be necessary to resort to the habitual use of the catheter. When the "residual" urine amounts to four ounces or less, the catheter need only be passed once a day, preferably at bedtime. If six ounces are retained the catheter should be employed twice daily; if eight or ten ounces, three or four times daily. But there should be no limitation to any specific hour; the urine should be drawn off before

marked discomfort is felt. The patient should never be without a catheter, and the sooner he recognizes that the primary duty of his life is the employment of his catheter the better. A soft *coudé* catheter, No. 7 to 9 E, is the best for habitual employment. Thorough instruction in the passage of the catheter will give the patient the confidence necessary for its use. It is useless to lay down an elaborate ritual of urinary asepsis; in soap and water we have an efficient, convenient, and practical method for cleansing catheters. After cleansing, they should be kept in a corked glass tube.

The most important part of the general treatment is the regulation of the bowels; constipation aggravates the urinary symptoms. For this purpose nothing is better than confection of sulphur or senna, or equal parts of both. Opium may be given for pain, but never with belladonna, as the latter paralyzes the muscles of the bladder.

Urinary Fever in Connection with Catheterism.—This complication may occur under the strictest antiseptic precautions, and with the utmost skill in passing the catheter. A rigor will probably occur and the temperature may rise to 103° F., to fall again rapidly. Or the fever may be of a continuous character for some days. The general treatment is the same as that following instrumentation of the urethra.

Cystitis.—This is a common complication, and the best drug to administer is boric acid in ten-grain doses four times daily. When pus forms, the bladder must be washed out once or twice daily with disinfectants or astringent lotions. Permanganate of potassium (1 in 5,000) and perchloride of mercury (1 in 10,000) make excellent injections, but the best is nitrate of silver, beginning with a strength of 1 in 4,000 and gradually increasing to 1 in 750. Great pain and scalding at the neck of the bladder is best treated by "instillations" of strong solutions of nitrate of silver (one to three per cent.) All lotions should be warmed to 100° F.

Complete Retention of Urine.—This complication, which is liable to occur suddenly at any time, should be relieved immediately. A soft catheter should be first tried, followed in succession by a *coudé* catheter, a gum-elastic catheter, first alone and then mounted on a stylet, and finally a metal catheter. Should these all fail, suprapubic aspiration should be performed, when a catheter can probably be introduced. If not, the bladder must be tapped suprapubically with a trocar and cannula, and drained for some days.

Præ-prostatic Pouch.—A good-sized pouch may form in front of the middle lobe of the prostate, which may contain "residual" urine, and lead to confusion. A stone may form in this position.

Hæmorrhage from the Prostate.—When the disease is well advanced, this complication is always liable to occur. As a rule, the blood is mixed with urine, but it may be pure. The treatment consists in perfect rest in bed and the administration of opium. Styptic drugs are of no avail.

Operative Treatment of Enlarged Prostate.—The various recognized surgical procedures employed for this disorder may be briefly classified as follows: 1. Radical operations, which aim at removing the obstructing portion of the glands. 2. Operations undertaken for the purpose of inducing atrophy of the prostate—(a) castration; and (b) excision of the vasa deferentia. 3. Palliative operations—(a) drainage of the bladder through the perinæum; and (b) drainage of the bladder above the pubes.

The author discusses these various procedures, their methods of performance, and their advantages and disadvantages. The most valuable of the radical procedures for the removal of prostatic outgrowths is suprapubic prostatectomy. Vasectomy is preferable to castration, as being practically unattended by danger to life and free from the sentimental objections incidental to castration. But it is not quite so effectual in inducing atrophy of the prostate.

Some Cases of Head Injury, Including One in which there was Lesion of the Occipital Lobe. By H. W. Page, F. R. C. S.—When there has been no obvious injury to the scalp or the skull, and the injury is of parts within the closed cavity of the cranium, there may be great difficulty in diagnosis and decision as to treatment. The following should be looked for most carefully: hæmatoma in the occipital region, bleeding or escape of cerebrospinal fluid from the ear, bleeding from the mouth or nose, subconjunctival hæmorrhage, vomiting of blood, signs of paralysis, however trifling, in the face or limbs, inequality of the pupils, changes in the character of the unconsciousness, and convulsive seizures. The author reports three cases of head injury.

In the first case, that of a boy aged fifteen years, who had been struck in the occipital region, there was temporary blindness in the left side of both visual fields, implying a loss of function in the right half of each retina. This blindness disappeared within four months after the injury. In the second case, a large hæmatoma in the right frontotemporal region was incised, in the belief that the skull was fractured beneath it. But the supposed fracture was found to be the normal depression of the bone immediately behind the anterior part of the temporal crest. The third case was an example of so-called uncomplicated concussion, which the author cites to show that after all injuries of the kind the brain itself almost certainly suffers lesion. In fatal cases there are hæmorrhages, minute or large, in some part of the brain substance, and very commonly there is extravasation of blood into the arachnoid cavity.

A Series of Ten Successful Cases of Cæsarean Section. By Dr. W. J. Sinclair.—The author's article is based upon a series of ten cases of Cæsarean section, all resulting successfully for both mothers and children. He gives details of all the cases, reserving to the end some criticisms and remarks on indications and technique. The incision of the uterus is invariably to be postponed until the uterus can be drawn forward out of the abdominal wound, and an elastic tube should always be put round so as to be ready to compress the uterine vessels in case of emergency. The incision in the uterus should be sufficiently large; an added half inch or more of a clean incision is a small matter compared with laceration of the uterus or asphyxia of the fœtus. Wherever the uterine incision is made, the fundus uteri should be left free. In the author's cases the incision was made in the most obvious position; viz., the middle third in front and in the median line. A month after operation the uterus will be found to be just exactly in the position where it remains after a successful ventrofixation operation. If another pregnancy should occur, the fundus is free to rise and develop.

An Account of the Epidemic Outbreak of Arsenical Poisoning Occurring in Beer Drinkers in the North of England and the Midland Counties in 1900. By Dr. E. S. Reynolds.—The author's attention was first drawn to the subject in June, 1899, when he noticed an unusual number of cases of various skin eruptions, and later of

peripheral neuritis. Observing that the skin eruptions (herpes) occurred in the patients suffering from neuritis, he suspected arsenical poisoning, due to the beer which was the apparent cause of the multiple neuritis. Analysis of the beer confirmed this view. It is estimated that at least 2,000 persons have suffered from arsenical poisoning. The patients usually complain of burning and tingling of the hands or feet, and general malaise. Their faces are puffy and dusky, their eyes suffused and watery, and the walk is that of a patient with very sore feet. The skin lesions may be classified as follows: (a) Erythromelalgia. (b) Keratosis. (c) Erythemata. (d) Pigmentation. (e) Herpes zoster. (f) Nutritional disorders of the nails. (g) Loss of hair.

Sensory affections are present in all cases, varying from paræsthesia and tingling to numbness and anæsthesia, which last is, however, never complete. The motor symptoms are similar to those ordinarily found in so-called alcoholic neuritis. In many of the cases of advanced paralysis there is the peculiar mental condition commonly found in alcoholic paralysis. It may be described as a total loss of memory of time, and then of place. Any suggestion is at once accepted, however absurd. In the majority of cases there is some heart failure, limited to irritability or extending to acute dilatation. (Edema is present in about twenty-five per cent. of the cases. Just as the skin is irritated by the arsenic so the respiratory mucous membrane seems to be in its whole course; laryngitis and bronchitis are very common. In many cases digestive disturbance is the first sign of trouble.

Arsenic is almost certainly a cumulative poison, and affects the skin, the respiratory, and the digestive mucous membranes, the nerve trunks, both sensory and motor, the muscles (including the heart muscle), and the liver. The sequence of the symptoms is: (1) digestive symptoms; (2) laryngeal catarrh, bronchitis and acute skin symptoms; (3) disturbances of sensibility; and (4) motor paralysis (with pigmentation and keratosis). The course of the disease is slow; recovery does not take place for from eighteen months to two years. In most cases where death takes place, it is due to cardiac failure. The cases may be roughly divided into groups: (1) those with all symptoms fairly well marked; (2) those principally with skin lesions; (3) those principally with cardiac and hepatic lesions; and (4) those principally with paralytic lesions. The article closes with a statistical summary of all the cases personally seen by the author. Because of the affection of the heart muscle, the use of all depressing drugs (phenacetin, etc.) must be carefully avoided.

Cases of Arsenical Peripheral Neuritis. By Dr. R. J. M. Buchanan.—The author reports a series of sixteen cases of arsenical peripheral neuritis seen by him during the recent epidemic in Liverpool, and describes briefly some of the characteristic features noted in each case. He has no doubt that these cases were the outcome of arsenic in the beer used by the patients.

The Röntgen Rays and the Diagnosis of Urinary Calculi. By Dr. C. M. Mouillin.—The results obtained by Röntgen photographs may, so far as calculi are concerned, be regarded as final and conclusive for all ordinary cases. The Röntgen rays give definite and accurate information, not only as to the existence of a calculus, but as to its size, its exact position, and, what is even more important, whether there are other calculi present. There need now be no fear of operating upon the wrong

organ or upon the wrong side. The best results are obtained with calculi composed of oxalate of lime. In many instances Röntgen photography is the only method by which the presence of a fixed calculus can be ascertained. When the stone has left the kidney and is passing down the ureter the condition of the patient is, as a rule, such that quiet examination is not possible. Under ordinary circumstances, the Röntgen rays are not required in cases of vesical calculus. But the only indication of a calculus may be an obstinate cystitis, and whenever this persistence is a prominent feature in association with enlargement of the prostate, a special examination should be made without further delay. And with the Röntgen rays the question can be settled without difficulty. There is no need for any exceptional apparatus. As a rule, the patient should be placed in a recumbent position, with the plate supported by a stout board beneath him, and an aluminum screen between the body and the tube. One of the chief difficulties is the patient's breathing, as the kidneys move up and down during even tranquil respiration. A firm abdominal bandage will often remedy this. Unless everything is certain a second examination should be made after a few days' interval.

Urotropine as a Urinary Antiseptic. By P. J. Cambridge, M. R. C. S.—Urotropine, when administered to healthy individuals, has no diuretic action nor does it cause any appreciable change in the chemical constituents of the urine. A curious effect produced is the sensation of formication, appearing on the fourth day, and followed in two days by an intense, red, measily rash. Both quickly disappear when the administration of the drug is stopped. Urotropine appears in the urine within ten minutes after the first dose is taken.

The author has investigated its action, both bacteriologically and chemically, and has reached the following conclusions: 1. Urotropine alone may, by prolonged heating, be made to yield formaldehyde, but this decomposition does not take place at body temperature. 2. An alkaline solution of urotropine may be similarly decomposed, but the body temperature is not sufficient to cause the change. 3. Dilute acids quickly decompose urotropine. 4. Acid salts—*e. g.*, of the urine—liberate formaldehyde from urotropine on boiling but not at 37° C. 5. The acid urine of a person taking thirty grains of urotropine a day does not contain formaldehyde.

As a urinary antiseptic, urotropine appears to be much superior to those usually employed, when the acidity of the urine is insured. By the systematic use of urotropine in all cases of typhoid fever the great danger of the spread of the infection from the urine may be entirely avoided.

Infective Parotiditis after Abdominal Section. By Dr. W. Elder.—The author reports a case of double infective parotiditis following an operation for appendicitis. Such cases have been known to occur, but in this instance there was a complicating circumstance in that the patient's brother had mumps forty-nine days previously.

A Case of Gangrene of the Penis. By G. A. Clarkson, F. R. C. S.—The author reports a case of gangrene of the penis occurring in a man aged fifty-one years, in which the determining factors were a feeble and dilated heart, extensive atheroma of the arteries, and possibly inoculation of some part of the urethra with infective organisms. The whole organ appeared to be in a condition of ordinary moist gangrene. Owing to the patient's general condition no operation was possible, and he died

three days after the first appearance of the gangrene. It seems hardly credible that an organ with the anatomical peculiarities of the penis could be the subject of dry gangrene, yet such has occurred.

British Medical Journal, January 19, 1901.

Malignant Diseases of the Female Genitalia. By Dr. T. Oliver.—*Malignant Disease of the Vulva.*—This may be epithelioma or sarcoma. It takes the form of ulceration or flattened nodular growths. It is to be distinguished from caruncle of the meatus urinarius, hard chancre, and soft venereal sore. The prognosis is bad and the author has never seen removal of the growth by surgical procedure do any good.

Malignant Disease of the Vagina.—Usually this canal is implicated secondarily through extension of the disease from the rectum, the bladder, or the uterus. It may be primary, in which case there will be felt an irregularly ulcerated and thickened mass in either the anterior or posterior wall of the vagina. Any surgical treatment of the nature of excision would be so severe that the result of the operation would probably be worse than the disease.

Malignant Disease of the Uterus.—Carcinomata originate under the flattened epithelium lining the vaginal face of the cervix, or in the columnar epithelial cells of the tubular glands of the cervical canal. Cancer of the uterus is conveniently divided into cancer of the cervix and of the body. Once the disease has taken a thorough hold upon the tissues of the cervix these may ulcerate. Ulceration and growth usually go on together, accompanied by considerable hardening and thickening around the margins; or the growth may sprout and form a cauliflower excrescence. In the cervical canal the disease proceeds stealthily and may remain undetected for a time. As the disease progresses, the canal widens, the rim of the os becoming thick, hard, and irregular. In cancer of the body of the uterus, the disease originates either in the ordinary epithelial cells or in the cells of the tubular glands (adenoma malignum).

There is no one symptom that is pathognomic of cancer. Irregular hæmorrhage or a thin, offensive, watery discharge are very frequent. The bleeding may appear only after coitus. The recurrence of bleeding in women who have passed the climacteric is most suggestive, and a thorough examination is imperatively called for. The treatment resolves itself into cases that are (1) unsuited, and (2) suitable, for operation. Where the disease is so far advanced that the uterus is fixed, where hæmorrhage is profuse and the discharges foul, scraping the ulcer and breaking down the brittle tissue and the application of a fairly strong solution of zinc chloride will relieve the symptoms. The author has tried Coley's coccal injections, but has never seen them cure a case.

Cases where the disease is limited to a very small part of the cervix, or if in the uterus where the womb is freely movable, with no indication in either instance of the disease having extended beyond the organ itself, are those suitable for operation. All things considered, the author is disposed to recommend total extirpation as against amputation.

Diagnosis in Cancer of the Body of the Womb. By Dr. M. Handfield-Jones.—Hæmorrhage is always the first symptom of cancer of the body of the uterus, but bleeding may also be due to some menopausal irregularity, to so-called senile endometritis, or to commencing adenoma. Apart from the consideration of the degree of malignancy in any given case, there is at the same

time the important question whether the growth, originally benign in character, has become affected with malignant degeneration.

The author concludes: 1. That in cases of corporeal cancer there is a stage of benign adenoma. 2. Uterine scrapings are not perfectly reliable, owing to the tissue being only superficial, and the deep part of the gland not being obtained. Later scrapings, when the disease is more advanced, are therefore more reliable. 3. Clinical signs are more valuable than microscopical evidence. 4. The degree of malignancy varies much, and the disease may run a very slow course. 5. Rapid increase in the size of the body of the womb is the most valuable sign in determining need for extirpation of the whole organ.

Spoon-shaped Indentations in the Skulls of the New-born. By J. M. M. Kerr, M. B.—Indentations of the foetal skull may be either spoon-shaped or furrow-shaped. The two varieties occur with about equal frequency. The furrow-shaped variety is much less serious, and seldom gives rise to much immediate trouble. The spoon-shaped indentations are situated usually on one or other of the parietal or frontal bones in the neighborhood of the anterior fontanelle. The accident, with few exceptions, occurs where there is a deformity of the maternal pelvis—generally the flat rachitic pelvis. In the majority of the cases, extraction has been completed by traction on the head or breech. The indentation is usually caused by the head being pressed against the projecting sacral promontory. Defective ossification of the foetal skull certainly predisposes to the accident. It is very doubtful if spoon-shaped depressions are ever due to forceps. The prognosis is not unfavorable. In the majority of cases the indentations disappear within a week and produce no ill-effects later. In other cases, although the child lives for days, weeks, or even months, there are very marked local and general disturbances. Such cases usually terminate fatally. And there is yet another group of cases where the child is born dead, or so deeply asphyxiated that if the indentation is not immediately relieved, death will certainly result. For the immediate relief of depressions of the foetal skull many devices have been tried and various operations performed. The author cites three cases where spoon-shaped depressions in the foetal skull were immediately relieved by forcible antero-posterior compression of the head, the depressions springing out with a snap in two of the cases.

Impacted and Displaced Gravid Uterus with Fibroid. By Dr. N. MacLeod.—An impacted, retroverted, or retroflexed gravid uterus, in which gestation is prolonged to term, is certainly an uncommon occurrence. The author reports the case of a woman aged thirty-four years, where gestation had taken place in a retroverted uterus with a large intramural fibroid, and had proceeded to term. A Cæsarean section was performed and the child removed alive, but it died five hours later. That part of the uterine wall containing the fibroid tumor was removed, and the patient made a good recovery. The uterus was so far retroverted that the cervix could not be felt at all, it being some three inches above the pubes. The case recorded in this paper differs from the seven cases previously reported, in the following points: (1) the nonobliteration of the cervix; (2) the impossibility of bringing the cervix into such a position as would enable delivery to take place through the vagina, and this even after control of the uterine body had been obtained through an abdominal incision; (3) delivery by Cæsarean section; (4) the presence of an intramural

fibroid, and (5) removal of the anterior uterine wall with the fibroid.

A Second Successful Case of Cæsarean Hysterectomy. By C. Campbell, M. R. C. S.—The author reports a successful case of Cæsarean section performed upon a woman aged twenty-four years. The operation chosen was a modified Porro, in which both child and uterus were removed and further pregnancies (and operations) thus prevented. In conclusion, the author expresses the hope that two successes so easily obtained may help to relegate craniotomy, the induction of premature labor, and symphysiotomy alike to the past.

Gazette hebdomadaire de médecine et de chirurgie, January 6, 1901.

Generalized, Acquired Telangeiectasis.—M. Léopold Lévi and M. Louis Delherm report such a case in a woman of thirty-three years of age, who suffered from obesity, chronic nephritis, and myocarditis. The disease is more common in women than in men, and may appear at any age. The infectious diseases, including syphilis, as well as the chronic diseases, may be forerunners, and persons who are "nervous" or suffering from nervous diseases seem to be subject to it. The telangeiectatic spots may appear as macules or in maculopapular form, discrete or confluent; they may be of reticular form or pseudo-erythematous. The areas may be few or many. The spots disappear upon pressure—a pathognomic sign.

Lyon médical, December 30, 1900.

Acute Tuberculous Appendicitis.—M. Maurice Patel reports the case of a man thirty-six years of age who was suddenly seized with great abdominal pain without assignable cause, which immediately became general. He manifested all the symptoms of an acute appendicular inflammation, with a general peritonitis. The appendix was found with difficulty at the time of operation, and foul-smelling pus was simultaneously evacuated. Microscopic examination of the appendix disclosed the undoubted tuberculous infection. The author reports a second case of recurrent appendicitis in a woman who gave a history of a former pleurisy and former hæmoptyses. Macroscopically, the appendix appeared to be tuberculous, but microscopic examination showed it to be the seat of a simple inflammatory process. The author lays stress upon the fact that microscopic examination alone can determine the nature of an appendicular inflammation. He says that a form of acute tuberculous appendicular inflammation exists which is a localization of a general infection, and which can be accompanied by peritoneal irritation as severe as that seen in perforating appendicitis. Surgical measures are indicated for the relief of the condition.

Physiological Action, Bacteriology and Therapeutics of Ozone. By M. H. Bordier.

Choice of Accumulators in Electrotherapy. By M. Chanoz.

Presse médicale, December 29, 1900.

Vincent's Angina.—M. Maurice Letulle reviews the bacteriological findings in cases of Vincent's angina also described as "ulcerative chancriform amygdalitis," acute ulcero-membranous angina," and "acute ulcerative lacuna amygdalitis"). The fusiform spirilla found in these cases are also present in other diseases of the mouth and tonsil, and the spirochætæ described as causative agents, are sometimes absent. While the author agrees that the condition is one which must be regarded as a pathological entity, he does not believe its causative actor has yet been demonstrated.

Calcified Subcutaneous Hygromata and Granulomata.—M. G. Milian says that these growths appear insidiously as painful swellings slowly increasing in size. The tumor is soft, fluctuating, and does not involve the skin. A yellowish discoloration can sometimes be seen through the skin above the tumor which is movable upon the underlying tissues, and is not adherent to the tendons or muscles. If the muscle is involved, it often becomes painfully contracted. The degree of consistence varies with the amount of calcareous matter contained. If the tumor is opened, a viscid fluid escapes, of whitish or yellowish color or of chocolate color if blood is mixed with the fluid. The fluid holds in suspension granules of yellowish calcareous substance. The process may remain localized or become general. The tumors may become spontaneously healed or may ulcerate, or they may produce trophic changes in the skin and may cause muscular atrophy. The author goes minutely into the pathological changes involved by these growths. The only treatment consists in extirpation.

Centralblatt für Gynäkologie, December 29, 1900.

Abdominal Total Extirpation of the Vagina.—Dr. Ernst Wertheim reports two cases in which the vagina was totally removed by the abdominal route, in the first instance because of carcinomatous involvement with the uterus, in the second because of a very friable epithelioma of the cervix, which had also involved the vagina. The author recommends the procedure because the field of operation is completely visible, and because the parametric connective tissue may be simultaneously removed. The ureters are exposed and thus prevented from being injured. Hæmostasis is easy with good assistance. The operation also permits complete abdominal closure of the peritonæum.

Total Abdominal Hysterectomy for Fibroids. By Dr. H. A. von Guérard.

Lactosalpinx with Twisted Pedicle. By Dr. J. Harpöth.

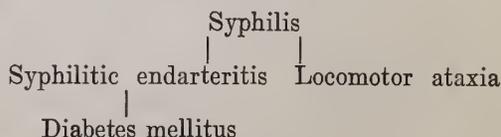

Centralblatt für Chirurgie, January 5, 1901.

Treatment of Shortening after Leg Fractures.—Dr. N. Kaefer says the three methods in use are: (1) Exact reposition under narcosis, by means of plaster; (2) extension by weights, and (3) by the elastic apparatus of von Eiselsberg, by which the parts, after partial enclosure in plaster of Paris, are subjected to a constant tug by means of heavy elastic bands secured in a movable metal frame. The author describes a modification of his own of the latter principle, which works by means of a screw attached to two plates.

Treatment of Patellar Fractures. By Dr. A. Wiener.

Wiener klinische Rundschau, January 6, 1901.

Tabes and Diabetes Mellitus.—Professor J. Pal reports a case of locomotor ataxia, the patient having simultaneously a diabetes mellitus. Pal says that the circumstance is either purely a coincidence or that the two diseases rest upon a common basis. He thinks the latter may be the case, as follows:

He thinks that tabes stands in the same relation to diabetes as to aortic insufficiency, from which many patients with locomotor ataxia suffer.

Patellar Reflex after Supralumbar Horizontal Division of the Spinal Cord. By Dr. L. Bruno. (*To be continued.*)

Psychical Epilepsy Cured by Operation.—Dr. Alexander Pilcz reports such a case. (Those interested should consult the original article.)

Riforma medica, December 24, 1900.

Diffuse Subcutaneous Emphysema in a Case of Acute Melancholia. By Dr. Vitige Tirelli.—The patient was a young man aged twenty-one years, who was affected with melancholia, accompanied by acute attacks of maniacal excitement. After a particularly severe attack of this kind a diffuse subcutaneous emphysema was noticed, especially on the cheeks, somewhat less marked on the neck and back. Crepitus and small bullæ were discovered along the course of the right femoral artery. The ribs were sound and there was no trace of any thoracic lesion. After another attack of mania, the emphysema around the neck increased, and large bullæ appeared here and there at the upper part of the chest. The nose, the forehead, the scalp, and the ears were free from emphysema. No œdema was present in the affected parts; there was no dyspnœa; swallowing and urination were free. On the following day the emphysema diminished to a certain extent, and two days later it disappeared almost entirely, while the mental condition remained the same. The patient died about a month later, and the autopsy showed the presence of fresh adhesions in the upper part of the pleura. The author thinks that these adhesions offered a place of lesser resistance, and that the lung may have given way at some point opposite the adhesions, the air thus spreading under the skin.

Vratch, December 9 (O. S. 21), 1900.

Concerning the Cryoscopic Method of Examination as Applied to the Testing of Pharmaceutical Preparations. By Dr. A. v. Poehl.—An account of the possibilities of cryoscopy, or the art of determining the freezing-point of a solution or mixture, in the examination of extracts of drugs, of mineral waters, etc.

Self-intoxication as a Result of Fatigue of Nerve and Muscle. Organotherapy. By Dr. A. v. Poehl.—The author has examined the urines of race-riders on bicycles and found that over-exertion is always accompanied by a certain degree of self-intoxication. He found that the relation of the nitrogen of the urea to the total nitrogen of the urine—the so-called coefficient of oxidation—was diminished; that the proportion of uric acid to that of phosphoric acid was markedly increased; that the proportion of phosphoric acid which existed as sodium phosphate to the total amount of phosphoric acid was increased, and that the absolute osmotic pressure of the urine fell considerably. These chemical facts show that the energy of oxidation is diminished by fatigue, and that in over-exertion the alkalinity of the tissue-fluids is diminished, the quantity of intermediate products containing nitrogen is increased, while the osmotic pressure of the body-fluids is lowered, and their metabolism retarded. The author also found in bicyclists who participated in a recent long-distance race from St. Petersburg to Moscow, congestion of the kidneys, and not only hyaline, but also finely granular casts. He attributes these effects of fatigue on the kidneys to self-intoxication due to an enfeebled internal oxidation. The author also investigated the urines of a number of young men engaged in serious studies and has found that mental exertion produces very similar effects on the metabolism and results in self-intoxication. He found, however, that in these cases, there

were, in addition to the changes detailed under muscular fatigue, a relative diminution of the chlorides (as compared with the amount of urea) and a relative increase of the sulphuric acids. The first is a sign which accompanies anæmia; the second indicates derangements in the process of fermentation in the digestive tract. The treatment of both mental and physical over-exertion should therefore aim to increase the internal respiration and the alkalinity of the body-fluids. One of the organic extracts, spermine, has the property of markedly increasing the alkalinity of the blood, and is therefore indicated in these conditions. The author's clinical experience confirms these theoretical considerations.

Secondary Simple Pneumothorax in a Case of Emphysema. By Dr. D. I. Vieriujsky.

The Significance of Injuries in Public Life, especially in the City of Moscow. By Dr. A. P. Levitzky

Dublin Journal of Medical Science, December, 1900.

Fractures of the Pelvis. By E. H. Bennett, M. D., F. R. C. S. I.—In a paper read in the Section of Pathology of the Royal Academy of Medicine in Ireland the author showed pathological specimens of extensive fractures of the pelvis to prove the possibility of recovery after most severe injuries of that region.

Porro's Operation (Extraperitoneal)—A Successful Case for Ruptured Uterus, Complicated by a Large Myoma and a Five-and-a-half-months' Pregnancy. By George Cole-Baker, M. D.

The Operative Treatment of Cleft Palate by a New Procedure. By Edward H. Taylor, M. D., B. Ch., F. R. C. S.—The author describes the operation as follows:

The patient is placed on a low table, the head well thrown back, and the vertex looking directly downward—Rose's position—and chloroform is administered. Smith's gag is then introduced into the mouth, and the edges of the cleft pared freely. The blood which quickly fills the mouth is removed by means of a suction apparatus, somewhat similar to that recommended by Mr. Robert H. Woods in connection with extirpation of the larynx (*Excision of Right Half of Larynx*, by Mr. R. H. Woods. *Transactions of the Royal Academy of Medicine in Ireland*, Vol. xiv, 1896). Throughout the operation, sponges are dispensed with so far as possible, pressure with the finger on the bleeding point proving sufficient. A curved incision is now made on each side close to the alveolar margin of the palate, commencing posteriorly inside the last molar tooth, and curving round anteriorly to terminate in the cleft, and arranged at the same time in such a way that sufficient tissue is left immediately behind the incisor teeth to hold a suture subsequently. With this incision the posterior palatine artery is retained in the flap. The latter is reflected by means of a rugine, an instrument which enables one to lift the muco-periosteal flaps very rapidly and without laceration or serious damage. I regard the various forms of raspatory used for detaching the soft tissues from the palate as quite unsuited for the purpose. Some are very narrow, with sharp-pointed tips, and consequently are in the highest degree calculated to damage the tissues which they are meant to detach. The rugine, on the other hand, which I employ has a fairly broad anterior extremity, and the inclination of its free edge is very abrupt, forming an angle of about 60° with the horizontal. It is therefore in no sense of the term a cutting instrument; but, while it insures the minimum of damage to the palate tissues, it separates the flaps with

the utmost facility. The next step in the operation is to sever the connections between the hard and soft palate on their nasal aspects. This step is much facilitated by turning back the flaps which have been already detached from the hard palate, and a knife or curved scissors may be employed for the purpose.

In all cases hæmorrhage is to be avoided as much as possible. Loss of blood is badly borne by young children, and may be followed by serious consequences. Free hæmorrhage, too, floods the mouth, and greatly obscures the confined field of operation. It can be obviated best by making the incisions as recommended; and when the flaps are being separated any undue bleeding may be easily controlled by pressing these firmly against the bony palate and waiting for a few seconds. Therefore, too great haste at this stage of the operation is to be avoided, and blood and saliva should be removed from the mouth by means of suction rather than by vigorous sponging.

The author usually employs silkworm-gut sutures. In introducing them it will probably be most convenient to commence behind and come forward. Small *curved needles passed with a needle holder* may be used; but, if preferred, a curved needle in a handle may be substituted for them. It is very striking to observe the facility afforded by the mobility of the flaps in carrying out this stage of the operation. At the anterior extremity of the cleft the suture should be passed through the flap from its mucous to its periosteal aspect; the free end of the suture is then carried through the gum, behind the incisor teeth in the reversed direction—viz., from its deep to its superficial aspect. This suture anchors the flap in front during the process of healing. Should it be deemed insufficient an *accessory suture* passed further out on each side will afford ample security. Difficulty may be experienced in bringing the flaps into apposition at the level of the hard and soft palate, and seeing how unfavorable a high degree of tension is for securing good and rapid union it will be well, following the advice of Dieffenbach, to make an antero-posterior incision in each side, about half an inch in length, at the inner side of the hamular process. These incisions, in addition to relieving tension, secure rest for the palate, owing to the division of the fibres of the levator and tensor palati muscles; and any harmful traction influence which these might exert is therefore obviated.

The author claims for this operation over others: (1) Greater ease and rapidity; (2) absence of troublesome hæmorrhage; (3) security of blood supply; (4) ease of introduction of sutures, and (5) simplicity of postoperative details.

The Relation of Veterinary Science to Human Medicine. By Sir Christopher J. Nixon, M. D., LL. D.

Letters to the Editor.

DYSPEPTIC ASTHMA AND DISPLACEMENT OF ABDOMINAL ORGANS.

113 HANCOCK STREET, BROOKLYN,

January 14, 1901.

To the Editor of the *New York Medical Journal*:

SIR: I have read, with great pleasure and interest, in your issue of January 12th, the article by Dr. Frank H. Murdoch, entitled *Dyspeptic Asthma*. It is a condition to which little reference, at least so far as I have observed, has been made outside the text-books. I have

seen cases in which the trouble went even so far as to produce syncope, due simply to over-distention and pressure effects. My object, however, in writing springs from the belief that in many of these cases the symptoms are, in a measure, *reflex* in origin, due to a low position of one or both kidneys and the stomach or to gastropnoia alone. I have noted in Dr. Murdoch's paper that in Case I he mentions that the stomach was in normal position, also in Case II. In Cases III, IV, and V, however, he does not speak of the situation of the organ. I should like to hear if in the many cases of this nature there has not been observed a connection between *ptoses* of the various abdominal organs and this condition known as dyspeptic asthma. To my mind there is. As to the management of the trouble, I should like to suggest the application of a plaster bandage to the lower abdomen, as described by Dr. Rose in the *Post-graduate* for March, 1900, and by myself in the *Medical News* for September, 1900. This method will without doubt relieve those patients for whom a simple dietary and secretion-correcting regimen is insufficient.

H. W. LINCOLN, M. D.

Book Notices.

The Care of the Consumptive. A Consideration of the Scientific Use of Natural Therapeutic Agencies in the Prevention and Cure of Consumption, together with a Chapter on Colorado as a Resort for Invalids. By CHARLES FOX GARDINER, M. D., Non-resident Fellow of the New York Academy of Medicine, Member of the American Climatological Association. New York and London: G. P. Putnam's Sons, 1900.

The author has given us in this little work a *résumé* of the modern treatment of pulmonary tuberculosis. He emphasizes the personal hygiene of the patient, the importance of out-door life, of suitable clothing, of good, nutritious food, and of proper occupation and exercise. There is a very readable chapter on the care of the children of consumptives, with special reference to their physical development and attention during such illnesses as are likely to leave pulmonary tuberculosis as a sequel. The closing part of the book is devoted to a rehearsal of the advantages of Colorado as a resort for tuberculous subjects.

Obstetrics. A Manual for Students and Practitioners. By DAVID JAMES EVANS, M. D., Lecturer on Obstetrics and Diseases of Infancy, McGill University, Montreal, etc. Series Edited by BERN B. GALLAUDET, M. D., Demonstrator of Anatomy and Instructor in Surgery, College of Physicians and Surgeons, Columbia University, etc. Illustrated with One Hundred and Forty-nine Engravings. Pp. 3 to 430. Philadelphia and New York: Lea Brothers & Company, 1900. [Price, \$1.75.]

In this small work the author has attempted to condense obstetric data into a space consistent with clearness. He has succeeded, we think, exceptionally well. The main topics of the physiology and pathology of pregnancy, parturition, and the puerperium are touched upon, and enough is written to give a lucid understanding of the subject. The book is not intended, of course, for reference. For a brief work for the student, it answers all purposes.

Le pneumocoque et les pneumococcies. Par ADRIEN LIPPMANN, Interne des hôpitaux de Paris. Préface du Dr. DUFLOCCQ, Médecin de l'Hôpital Tenon. Avec 2 figures dans le texte. Pp. 5 to 96. Paris: J. B. Baillière et fils, 1900.

IN this monograph the author has covered a large experimental and clinical field. He has considered the life history of the Fränkel-Weichselbaum diplococcus and its cultural and biological peculiarities. He has studied its manifestations when experimentally or clinically found in the various organs of the body, especially pneumonia, the arthritides, peritonitis, and cerebrospinal meningitis. He believes that, judging from published evidence and his own observations, much may be expected in a therapeutic way from serum treatment when the pneumococcus is the invading micro-organism.

Essentials of Histology. By LOUIS LEROY, B. S., M. D., Professor of Histology and Pathology in Vanderbilt University, Medical and Dental Department; City Bacteriologist to Nashville, Tenn., etc. Arranged with Questions following each Chapter. With Seventy-two Illustrations. Philadelphia: W. B. Saunders & Company, 1900.

THIS compend embraces the essential points in the histological diagnosis of tissues. It may be of use to students or graduates who wish to refresh their minds on the subject; but it is very superficial and the illustrations are essentially crude.

A Text-book of the Diseases of Women. By HENRY J. GARRIGUES, A. M., M. D., Gynæcologist to St. Mark's Hospital, New York City, etc. With 367 Illustrations. Third Edition, thoroughly Revised. Pp. 7 to 756. Philadelphia: W. B. Saunders & Company, 1900. [Price, \$4.50.]

IT is no doubt because it is such an eminently practical text-book that Dr. Garrigues's book on diseases of women has entered upon its third edition within six years from the date of its original publication. In the present edition we find many new illustrations and a greatly increased amount of very readable text, but no deviations from the cardinal principles of gynæcological treatment which the author laid down in his former editions. In no spirit of fault-finding, we offer the suggestion that in some one of the numerous editions of this work which we hope will follow this one the author limit his description of operations to the *one* which he would have his student or reader perform, rather than give the entire list of procedures for each condition. Dr. Garrigues's book is a capital exposition of modern gynæcology and is deservedly popular.

Therapeutisches Vademecum der Haut- und Geschlechtskrankheiten für praktische Aerzte. Von Dr. REINHOLD LEDERMANN, Spezialarzt für Hautkrankheiten in Berlin. Zweite durchgesehene und erweiterte Auflage. Berlin: Oscar Coblentz. 1901.

THE first edition of this work appears to have met with favor, for in two years the second revised edition has appeared. The first part of the work, and the larger part, is devoted to the treatment of the diseases of the skin, and many prescriptions are given for the treat-

ment of these ailments and their complications. The latter part of the book is given over to a consideration of the venereal diseases. The author favors the newer albuminous silver compounds for the treatment of gonorrhœa, while no new suggestions are offered for the therapeutics of syphilis.

BOOKS, ETC., RECEIVED.

Encyclopædia Medica. Under the General Editorship of Chalmers Watson, M. B., M. R. C. P. E. Volume V, Herpes to Jaws, pp. vi-536. Vol. VI, Joints to Liver, pp. vi-562. New York: Longmans, Green & Company, 1900.

Medico-surgical Aspects of the Spanish-American War. By Dr. Nicholas Senn, Lieutenant-Colonel and Chief Surgeon, United States Volunteers, etc. Pp. 10 to 379. Chicago: American Medical Association Press, 1900.

Flesh Foods, with Methods for their Chemical, Microscopical, and Bacteriological Examination. A Practical Hand-book for Medical Men, Analysts, Inspectors, and others. By C. Ainsworth Mitchell, B. A. (Oxon.), F. I. C., F. C. S., Member of Council, Society of Public Analysts. With Illustrations and a Colored Plate. Pp. xv-336. London: Charles Griffin & Company. Philadelphia: J. B. Lippincott Company, 1900.

Physical Diagnosis in Obstetrics. A Guide in Antepartum, Partum, and Postpartum Examinations for the Use of Physicians and Undergraduates. By Edward A. Ayers, M. D., Professor of Obstetrics in the New York Polyclinic, etc. With Illustrations. Pp. viii-276. New York: E. B. Treat & Company, 1900. [Price, \$2.]

Diseases of the Heart: Their Diagnosis and Treatment. By Albert Abrams, A. M., M. D. (Heidelberg), F. R. M. S., Consulting Physician for Diseases of the Chest, Mount Zion Hospital and the French Hospital, San Francisco. Pp. 172. Chicago: G. P. Engelhard & Company, 1901. [Price, \$1.]

Urinary Diagnosis and Treatment. By John W. Wainwright, M. D., Member of the American Medical Association, etc. Pp. 140. Chicago: G. P. Engelhard & Company, 1901. [Price, \$1.]

Rudiments of Modern Medical Electricity. Arranged in the Form of Questions and Answers prepared especially for Students of Medicine. By S. H. Monell, M. D., Professor of Static Electricity in the International Correspondence Schools, etc. Pp. 5 to 165. New York: Edward R. Pelton, 1900. [Price, \$1.]

Transactions of the American Orthopædic Association. Fourteenth Session, held in Washington, May 1, 2, and 3, 1900. Volume XIII.

New Inventions, etc.

A TURBIMATE-CUTTING FORCEPS.

BY GEORGE C. GAGE, M. D.,

NEW YORK.

IN cases of nasal obstruction due to hypertrophies of the turbinate bones and soft tissues, with the sequel of deficient and unequal air pressure in the middle ear, the arrest of treatment through the difficulty, and in many cases the impossible application, of sufficient air pressure, either by the use of the Politzer method or the

Eustachian catheter, also for the treatment of the many nasal reflexes due to such hypertrophies of the turbinates, we find it necessary to have recourse to operative measures for the removal of such redundancy of tissues by the use of some instrument which will not splinter, break, or leave spicula of bone to cause future trouble, or, in other words, "the remedy (in its results) should not be worse than the disease" treated.

In clinical work we meet more of these obstructive growths, especially of bone enlargement, in adults, who, fortunately, have in many cases wide and open *alæ*, allowing of the use of a larger and stronger forceps than could be used in childhood. A narrow-bladed cutting

forceps like the one here figured will permit the points to enter on each side of the turbinate bone, with the cutting edge uppermost, blades concave and fenestrated, with an open space at the bottom to allow for the yielding of soft tissues, while the upper edge makes a clean cut through the bone.

47 WEST FORTY-NINTH STREET.

Miscellany.

The Treatment of the Proteids of Cow's Milk.—Dr. T. M. Rotch (*Journal of the Boston Society of Medical Sciences*, November 20, 1900) says that for a long time we have known that the chief elements that we have to deal with in the composition of the total proteids in woman's and in cow's milk are caseinogen and lactalbumin, yet the casein resulting from the coagulation of the caseinogen in both milks differs so markedly in its size and consistency, and the cow's coagulum causes so much more gastric disturbance than does the woman's, that it has become a fruitful source of discouragement to those who are endeavoring to solve the problem of substitute infant feeding.

The total proteid of cow's milk is about three or four times as great as in woman's milk, and a great advance was made in the management of the total proteid in cow's milk when by means of exact methods we were enabled to order and obtain for the special infant the special percentage of total proteid indicated by the special conditions of the case. In this way the total proteid percentage in the infant's food could be made to correspond to the various total proteid percentages known to occur in woman's milk.

This advance was all the more marked since in previous years it had proved to be almost impossible to obtain by a home modification the exact proteid percentage that might happen to be desired. This inaccuracy arose chiefly from the necessity of using creams with different fat percentages to obtain a variety of proteid percent-

ages, making a somewhat complex problem, and one which resulted in the infant seldom getting the proteid percentage that the physician supposed he was providing. For this reason clinical investigations and results have been very inaccurate and misleading. Even when we were enabled to provide a food with the exact proteid percentage demanded, there was still a marked difference between the power of a special infant to digest exactly the same total proteid provided from woman's milk and from cow's milk, respectively, the former being far more digestible for the average infant than the latter.

In Europe the use of cereals, to make the coagulum of the cow's milk proteid finer, is almost universal, and in this country many physicians interested in the subject uphold this use. Much more has been claimed, however, for cereal dilution than is warranted by the later chemical and physiological investigations of White, especially in regard to the use of dextrinized cereals in place of a simple decoction of starch as in barley water.

This mechanical method of rendering the coagulum finer is crude and does not accomplish the desired result of making the casein of cow's milk correspond to that of woman's milk; it also necessitates the introduction of a foreign element, starch, into the food at a period of life when it is most objectionable. It has also been proved clearly by White that when the cereal diluent is dextrinized no greater effect is produced on the coagulum mechanically than when plain water is used.

The reason that some further treatment of the total proteid of cow's milk than that by mechanical division or peptinizing has been found necessary, is evident when we consider the analysis of woman's milk proteid in comparison with cow's.

According to König's analysis, the total proteid of woman's milk is shown to consist of two thirds lactalbumin and one third caseinogen, while in cow's milk the relative proportions are one sixth lactalbumin and five sixths caseinogen.

While, therefore, in the early period of its existence the human infant has its proteid digestion adapted to a high percentage of lactalbumin and a low percentage of caseinogen, we have been forced until lately to provide as a food one in which the proportion of lactalbumin is very low and that of caseinogen very high. The practical result accomplished by prescribing for definite percentages of lactalbumin and caseinogen, instead of for a total proteid, is that we can now materially reduce the coagulated caseinogen to the same percentage as occurs in woman's milk and yet retain the same high total proteid percentage which we had before.

There are at present, however, only certain combinations of the fat, sugar, lactalbumin, and caseinogen which can be provided. Thus, while we can obtain with various creams any percentage of fat, sugar, and total proteids required, we cannot, when varying percentages of lactalbumin and caseinogen are required, obtain a higher total percentage of proteids than 1.25, and of this the lactalbumin percentage cannot be obtained higher than 0.75, and the caseinogen higher than 0.50.

This is owing to the fact that the lactalbumin has to be obtained from whey, in which the lactalbumin is about one per cent. We are therefore, by this advance in the accuracy of our percentage prescribing, enabled to feed infants on a very low percentage of caseinogen at a period of life when this is especially indicated, and as they grow older the total proteid percentage can be gradually increased, as it naturally would when the power of digesting cow's milk caseinogen is acquired and

the necessity for a high percentage of lactalbumin in the total proteid becomes less.

To Clean Surgical Instruments.—The *Chemist and Druggist* for December 22, 1900, publishes an abstract of the thesis of a young Dutch surgeon, Dr. Jacques H. Polak, of Amsterdam, in which are given the results of a number of experiments made by him with a view of ascertaining the reliability and rapidity of the action of various methods of sterilizing. Although the most efficacious method is undoubtedly that of boiling the instruments, preferably in a two-per-cent. soda solution in a closed vessel, there are certain objections to this method, he says, as it is apt to blunt the keen edges of knives or the sharp points of needles. He has tried absolute and dilute alcohol, carbolic acid in two- and five-per-cent. solutions, formalin in the proportion of 1 to 500 to 1 to 1,000, and spirit of soap. Solutions of mercuric chloride attack the instruments, and are therefore unsatisfactory. Professor Straub, of Amsterdam, has adopted soap spirit as a disinfecting agent for his instruments in his practice, with most satisfactory results. The experiments were made with nickel-silver awls infected with pus swarming with the staphylococcus; in some cases the awls were infected with spores of anthrax. The awls were then placed in the disinfecting solution for periods varying from one minute to three hours, and subsequently inserted in agar and incubated. Dr. Polak got the best results with spirit of soap, which killed within the space of fifteen minutes the *Staphylococcus pyogenes* dried on the instruments. The spirit has, moreover, a valuable mechanical action, as it causes the pus to swell and thereby become more readily detached. Dr. Polak recommends the combined chemical and mechanical treatment of the instruments after each operation by first placing them in the soap spirit for a quarter of an hour, and then rubbing them for not less than half a minute with a cloth saturated with spirit of soap. It is desirable to place the instruments again in the soap-bath for a quarter of an hour immediately before an operation, and either to dry them with a sterilized linen cloth, or to remove the soap by means of a solution of alcohol (fifty per cent.), or a sterilized solution of boric acid. Dr. Polak used two varieties of spirit of soap, one consisting of:

Potash soap.	20	parts by weight;
Absolute alcohol.	29	"
Oil of lavender.	0.2	"
Water.	50.8	"

This is the Dutch *Pharmacopœia* formula; the other is the following, according to the German *Pharmacopœia*:

Potash soap.	15.4	parts by weight;
Absolute alcohol.	42.8	"
Water.	41.8	"

He found practically no difference in the action between them. Rectified spirit will, of course, suffice.

On the Physician's Reading.—At the dedication of the new medical library at Boston, Dr. Weir Mitchell, in a letter to the librarian, said:

"I see as I grow old—or may I say older?—how few are the young medical men whose tastes are scholarly, and who, like Holmes and our own lamented Da Costa, are familiar with the fathers and find pleasure in the old books—the quaint books, the sense and the vagaries of the past. Without a great library few can afford these intellectual playgrounds, or, indeed, acquire the material for such indulgence.

"May your new building and growing wealth of books tempt many into paths where some of us have found unlooked-for treasuries of interest, and even of practical value; for, indeed, the dying century did not invent common sense, and genius is of every age."

The decay of scholarly tastes among physicians is undoubtedly much to be regretted; but even in the ingestion of mental, as of material pabulum, a proper selection of food, and a healthy condition of the digestive organs, cerebral as well as abdominal, is needed, as was propounded in some remarks at the same meeting by Professor Osler with his enviable aptness of speech. Professor Osler said:

"But when one considers the unending making of books, who does not sigh for the happy days of that thrice happy Sir William Browne whose pocket library sufficed for his life's needs; drawing from a Greek testament his divinity, from the aphorisms of Hippocrates his medicine, and from an Elzevir Horace his good sense and vivacity. There should be in connection with every library a corps of instructors in the art of reading, who would, as a labor of love, teach the young idea how to read. An old writer says that there are four sorts of readers: 'Sponges which attract all without distinguishing; Howre-glasses which receive and powre out as fast; Bagges which only retain the dregges of the spices and let the wine escape, and Sives which retain the best onely.' A man wastes a great many years before he reaches the 'sive' stage."

Erotic Hallucinations.—Dr. E. Bellamy (*Journal de médecine de Bordeaux*, January 6th), in a Bordeaux thesis, says: Erotic hallucinations constitute a phenomenon, as frequent as important, of the neuroses and psychoses. They may be divided into (a) *genital*, (b) *extragenital*, according as they are occupied with the genital sense itself or with other senses.

The first class is manifested by all kinds of particular sensations, from the impression of contact or of the slightest friction up to the most acute orgasms of normal or abnormal sexual acts, the most horrible pains of violent sadism, or the most complete symptoms of pregnancy and parturition. The second class is manifested simply by sensations visual, olfactory, gustatory, or tactile, of an erotic character.

Erotic hallucinations are found especially in hysteria, in systematized insanities, the delirium of intoxication, and among the degenerate.

In *hysteria*, they are as often extragenital as genital. The sense of sight is most frequently affected, but it is seldom that there is not some affection of other senses. The hallucinations are produced in the dream state or in the subconscious condition, either by day or by night. Frequently painful, they may be accompanied by voluptuous sensations. Related by the subjects with a luxuriance, a precision of detail, capable of investing them with an air of reality, they have often served as a starting-point for self-accusation or calumnious denunciation, *e. g.*, the witches and sorcerers of the middle ages. They have a quasi-infectious property of communicating themselves.

In the *systematized insanities*, erotic hallucinations are capable of affecting all the senses. Those of sight are the most rare and imply a basis of a hysteropathic or alcoholic character. Those of smell, of taste, and especially of hearing, are the most frequent and varied. There are also genital hallucinations, properly so-called, in which all possible sensations may be encountered.

The erotic hallucinations of the delirium of persecution, the type of systematized insanities, are specially painful, and induce, on the part of the subject, in the genital form, characteristic defensive actions, such as crossing of the thighs, covering of the sexual organs, stuffing of the vagina with rags, paper, etc.

The subjects of *toxic delirium*, particularly alcoholics, have frequently erotic hallucinations; visual hallucinations, colored, mobile, multiple, most often tending to ideas of jealousy, *e. g.*, the vision of a wife or a mistress in indecent postures, in the arms of a lover, etc.

As to the *degenerates*, they are rarely subjects of hallucination. An exception must be made of the mystics, whose delirium, like that of the hysterics, with which it may have much in common, is accompanied by a great number of cases of erotic hallucinations. These hallucinations, essentially of dream-character, are genital or extragenital, and either voluptuous or painful, respectively, regarded as a mark of divine favor or torture, according as they are attributed to celestial or diabolic agency.

Syphilis in Arabia.—Dr. D. A. Zwrightman Van Noppen (*Medical Brief*, January), when at Djeddah, a city of Arabia, on the Red Sea, inquired into the native Arabian treatment of syphilis, which is prevalent in the country. In the Arabian language it is called El Adon (the great foe), or Mord-el-Rébir (the big evil), or Mord-Chine (the great nuisance). The treatment, after the Arabic prescriptions, is as follows: 1. A leech is fried to ashes in a new earthen pot. These ashes ought to be consumed by the patient in three days. If this does not help, the patient repeats it for seven days. 2. Fumigation of red precipitate of mercury. This medicine is put in a pot with burning coal, and the patient inhales the fumes, his head covered with a *burnoe*, a towel. After that the patient is, as a rule, salivated. 3. The patient eats for seven days nothing but couscous, an Arabian food prepared from chopped meat with flour or corn, without salt, pepper, or spices. He is then packed in sheets, and has to eat in the morning and at night powdered root of sarsaparilla, mixed with corn. Further, he has to drink for three days an aqueous decoction of sarsaparilla. After that follows a régime of three days' couscous.

Fracture of Cervical Vertebrae.—At a recent meeting of the Section in Orthopædic Surgery of the New York Academy of Medicine, Dr. Reginald H. Sayre related the case of a man who had been carried home unconscious after a fall on the head and neck about two months before. On his regaining consciousness, there was paralysis of the extremities, bladder, and rectum, in which there was slow improvement after two days. As every attempt to walk increased his symptoms, he was kept in bed several weeks. A diagnosis of fracture and dislocation of the fifth and sixth cervical vertebrae was made. The diagnosis was confirmed by Röntgen pictures, of which it had been necessary to take several from different points of view. One of the negatives was taken after fastening a bandage tightly over one shoulder and under the opposite armpit so as to make a gulch in which one edge of the plate had been forced so far as it would go. The pictures and a brace were exhibited. The latter consisted of a leather and steel collar attached to posterior steel rods and a pelvic belt. The head and neck would be thus fixed until consolidation was assured, the brace being capable of easy modification from time to time as the patient improved. The speaker recalled an almost exact counter-

part in a case which occurred several years ago in which the application of a jacket and jury-mast had been followed by disappearance of the paralysis.

Milwaukee the Healthiest City in the United States.

—The annual report of Dr. J. W. Coon, registrar of vital statistics of Milwaukee, indicates that Milwaukee is the healthiest city of its size in the United States, for though slightly larger than in 1899, the death rate last year was but 13.80 to the thousand, which is remarkable low. The number of deaths in Milwaukee last year was 4,001, while in 1899 it was 3,843. The comparative rates were 13.80 to the thousand and 13.48, respectively.

Laxness in Keeping Vital Statistics in Louisiana.

—Owing to the laxness of the parish boards of health in enforcing the law regarding the keeping of vital statistics, the State of Louisiana has never been able to furnish accurate and complete statistics regarding the health of its citizens. Such information is of great value as a guide in sanitary legislation, and Dr. Edward Souchon, president of the State board of health, is making renewed efforts to enforce the law requiring proper registration of births, deaths, and marriages.

A Physician the First Volunteer in the Civil War.

—Dr. Charles F. Rand, a retired physician of Washington, is said to have been the first soldier to enlist for service in the civil war. He enlisted at Batavia, N. Y., within less than ten minutes after the receipt of the telegram announcing the call for 75,000 troops by President Lincoln.

The Dignity of Medical Philanthropy in Russia.

—A recent decree of the Czar makes all physicians serving in dispensaries or other institutions receiving the poor gratuitously, and all physicians who give gratuitous instruction to sisters of charity in institutions connected with the Red Cross, officers in the Imperial service with all the privileges appertaining to this rank, and places them under the control of the Minister of the Interior.

When Police May Supply Medical Aid.

—Chief Devery issued an order recently empowering the police in Queens borough to employ a physician in case of accident to a citizen. The ambulance service in that borough is not such as is furnished in Manhattan and Brooklyn, where an ambulance with a surgeon normally reaches the scene of an accident within a few minutes. A call in Queens, where ambulances are widely scattered, usually is not answered in less than an hour, unless the accident happens to occur in one of the larger centres of population.

Proposed Changes in the Hospital Corps Insignia.

—The war department is considering important changes in the insignia of the hospital corps of the army. The brassard now worn by the privates and non-commissioned officers of that corps is essentially the badge of the Geneva convention, and consequently cannot be considered a distinctive mark for any single corps of the army. It is felt by the officials that this badge should not be worn except under the special conditions for which it was provided. It is therefore proposed to substitute for the brassard a modified Maltese cross of emerald green cloth, with a narrow white border of the same shape as now worn by officers of the medical department. It is also proposed to have a modified Maltese cross of unburnished

gilt material as a cap ornament for enlisted men of the hospital corps.

Ichthargan, a New Silver Salt.—Aufrecht (*Deutsche medicinische Wochenschrift*, 1900; August 2, *Therapeutische Beiträge*, No. 4) studies the properties of this new silver preparation, which is supposed to be a substitute for mercuric bichloride. The disadvantage of the silver salts heretofore employed, such as argentonin, argonin, protargol, largin, etc., is that they are weak and comparatively poisonous, while nitrate of silver is too superficial in action and too irritating.

Ichthargan is stated to be free from these disadvantages. It contains 30 per cent. of silver, and in this respect approaches AgNO_3 , which contains 63.5 per cent. of silver. Ichthargan is a compound of 15 per cent. of ichthyol and 30 per cent. of silver. It occurs as a dark-brown amorphous powder, odorless, and easily soluble in water of neutral reaction, in glycerine, in dilute alcohol; but insoluble in concentrated alcohol or ether. The aqueous solutions decompose in the presence of light, but can be kept for a long time in good condition in dark bottles. Concentrated solutions give a sediment with sodium chloride and with small quantities of albumen. The sediment dissolves in an excess of albumen. Ichthargan penetrates more deeply into the tissues than silver nitrate and the antiseptic properties of the new preparation are very strong, much stronger than those of silver nitrate in the same concentration. Experiments on animals show that ichthargan acts injuriously only when given in doses exceeding 0.1 to 0.15 per kilogramme of body weight, *i. e.*, in such quantities as are never prescribed.

Globon, a New Nutrient Substance.—Adolph Hoff (*Aerztliche Central-Zeitung*, 1900, No. 19) studies the properties of a new concentrated food called globon. This substance occurs as a yellowish white powder, odorless and tasteless, and is obtained by the decomposition of phosphorus-containing paranucleoproteids. It is easily digested in the stomach and in the intestines, and is easily peptonized; it is therefore indicated in those cases in which the power of the stomach to digest albumen is diminished or absent, and also in other disturbances of the stomach and the duodenum. Globon has also proved very useful in pneumonia, typhoid fever, severe forms of influenza, and in tuberculosis. Considerable success has also been obtained in carious disease of the bones and in rickets, in a case of stenosis of the pylorus as the result of cancer and in ulcer of the stomach. In those cases in which it could not be given by the mouth globon was administered in the form of nutrient enemata containing 250 cubic centimetres of milk, the yolks of two eggs, a spoonful of red wine, a pinch of salt and 20 cubic centimetres of globon. These enemata were used also with marked success in cases of intractable hysterical vomiting, as evidenced by the gain of the weight of the patient.

The Diagnosis of Stone in the Kidney.—Dr. H. D. Niles (*Denver Medical Times*, December, 1900), in a paper read to the Rocky Mountain Interstate Medical Association, emphasizes the following conclusions:

1. Stone in the kidney occurs more frequently than is generally supposed. 2. We are all prone to overlook any but the most characteristic manifestations of stone in the kidney. 3. Whenever a patient presents symptoms of renal insufficiency or systemic infection of obscure origin, we should include the kidneys in our search for the cause. 4. The value of the x-ray pictures depends entirely upon whether they give positive or negative

evidence. 5. It is from the use of the Harris instrument that we must obtain our most reliable information in cases where the classical symptoms are absent. 6. The methylene-blue color test in connection with the Harris instrument promises to be a useful addition to our present means of diagnosis. 7. In this branch of surgery our present need is for greater alertness and accuracy in diagnosis rather than improved operative measures.

Acetic Acid as an Antiseptic.—Fürst (*Deutsche Aerzte-Zeitung*, June 15, 1900) speaks of the ordinary vinegar of the household as an efficient antiseptic for the hands of the surgeon in cases of emergency when no other disinfectant can be obtained. After washing the hands with hot water and a potassium soap, and rinsing in hot water, Fürst dips the hands into a warm solution of vinegar. The latter, in the strength of 0.6 per cent. to 1 per cent., inhibits the growth of some nonpathogenic germs, and kills many pathogenic organisms.

The Varieties of Membranous Angina.—Dr. William G. Bissell (*Buffalo Medical Journal*, December, 1900) sums up his paper with the following conclusions:

1. The streptococcus pyogenes and the micrococcus of sputum septicæmia can produce membranous anginas, accompanied by physical disturbances sufficient to result in death. 2. The oïdium albicans produces pseudo-membranous exudates easily mistaken for a Klebs-Löffler inflammation. 3. The only positive means of determining a Klebs-Löffler infection is by microscopic methods. 4. From the sanitary standpoint, as regards quarantine, anginas due to the streptococcus pyogenes, micrococcus of sputum septicæmia and the oïdium albicans, require little consideration.

Oxaluria.—Dr. Helen Baldwin (*Journal of Experimental Medicine*, October 1, 1900) reports a careful experimental study of oxaluria, with special reference to its fermentative origin. As a result of this study she arrives at the following conclusions: 1. As varying amounts of calcium oxalate may be held in solution in the urine, conclusions based upon the presence or number of calcium oxalate crystals found therein are of no real value as an indication of the quantity of oxalic acid present. 2. Unless the utmost care is exercised, the results obtained by quantitative estimation of oxalic acid are subject to large percentages of error. This is especially true in the use of Neubauer's or Shultzen's methods, in which the calcium oxalate is precipitated in an alkaline solution. 3. An ordinary mixed diet regularly contains traces of oxalic acid or its salts. 4. A portion of the oxalic acid ingested with the food may be absorbed and reappear unchanged in the urine. 5. The normal daily excretion of oxalic acid in the urine fluctuates with the amount taken in the food, and varies from a few milligrammes to two or three centigrammes, being usually below ten milligrammes. 6. In health, no oxalic acid, or only a trace, is formed in the body, but that present in the urine has been ingested with the food. 7. In certain clinical disturbances which in some of the cases studied were associated with absence of free hydrochloric acid from the gastric juice, oxalic acid is formed in the organism. 8. This formation in the organism is connected with fermentative activity in the alimentary canal. (a) The prolonged feeding of dogs with excessive quantities of glucose, together with meat, leads eventually to a state of oxaluria. (b) This experimental oxaluria is associated with a mucous gastritis, and with absence of free hydrochloric acid in the gastric contents.

A CASE OF GASTRO-INTESTINAL HÆMORRHAGE CAUSED BY

FATTY DEGENERATION OF THE RIGHT VENTRICLE OF THE HEART.

By CHARLES PHELPS, M. D.

THE patient, a gentleman fifty-eight years of age, had always been a good liver, and in consequence had accumulated much abdominal adipose tissue and had acquired a small umbilical hernia. He had suffered from no other ailment than gout and indigestion. In time he had tired of wearing a protective pad which had been applied to his hernia, and resolved upon radical cure by operation, to which he was submitted December 30, 1899. The operation was simple and without incident of note except that anæsthetics were badly borne; his breathing was irregular, and he was exceedingly cyanotic during the whole period of operation. Reaction was not delayed, and he slept well through the night.

On the following day he took nourishment at intervals and had no discomfort except a slight headache. His morning temperature was 99.6° F., his pulse 78, and his respiration 17; in the evening his temperature was 100.2° F., his pulse 82, and his respiration 19.

On the second day after the operation his bowels were evacuated by an enema; he had severe headache with nausea throughout the day, and once vomited a little yellow fluid. His temperature rose from 99.8° F. in the morning to 102.2° F. in the evening, his pulse from 82 to 107, and his respiration from 18 to 25. He rested fairly well during the early part of the night under the influence of morphine, and toward morning vomited again a little fluid, which was this time of a greenish color.

On the morning of the third day after the operation his temperature was 99.8° F., his pulse 88, and his respiration 18. He suffered some abdominal pain, which was relieved by morphine, once repeated in the afternoon. In the evening his temperature rose to 103° F., and his pulse to 110, his respiration not being accelerated. Vomiting was frequent. He slept little during the night and became very restless.

On the morning of the fourth day his temperature was 103.4° F., his pulse 126, and his respiration 27, but he complained of little pain or discomfort and had no vomiting. At 11 o'clock he was in a condition of collapse; his skin was dusky, his extremities were cold, and his pulse was almost imperceptible. A high rectal injection of hot saline infusion was rejected, stained with blood; this gave the first intimation of the cause of the patient's collapse. At 1 o'clock P. M. his temperature was 105° F., his pulse 144, and his respiration 26. Large and frequent discharges of blood through the rectum continued during the afternoon and evening, and toward night he became delirious. At 10 o'clock P. M. hæmorrhage from the rectum ceased, and at 1 o'clock A. M. was succeeded by hæmatemesis. At 4 o'clock A. M. he died, soon after a large gastric hæmorrhage.

The urinary excretion was abundant at all times after the operation, and was of normal character.

Necropsy.—The wound of operation was closed by primary union throughout its length and depth, and the peritonæum and peritoneal cavity were normal. The subcutaneous adipose layer was very thick and the omentum and appendices epiploicæ were laden with fat. The

lower half of the ileum, the colon, and the rectum were filled with blood. The intestinal tract throughout its length was devoid of apparent lesion. The stomach contained a small amount of blood, and its mucous membrane was soft and eroded.

The liver was slightly enlarged, and a section examined by Dr. Harlow Brooks at the Carnegie Laboratory indicated:

1. Moderately extensive fatty infiltration.
2. A less decided cortical atrophy due to chronic passive congestion.
3. Marked obliterative arteriosclerosis (endo-arteritis) of the small branches of the hepatic artery.
4. A moderate degree of chronic interstitial hepatitis.

The lungs were small, and nearly bloodless, but otherwise of normal appearance.

The heart was of normal size. Its right ventricle was covered with a layer of fat at least three fourths of an inch in thickness, and the wall of this ventricle was of no greater thickness than paper and almost pultaceous in character. The left side of the heart was less encumbered by fatty deposit, and had suffered less fatty degeneration of its fibre. The left ventricle was firmly contracted and empty of blood; the right ventricle contained blood in small amount.

The extent to which the cirrhotic disease in the liver had advanced was obviously insufficient to account for the fatal gastro-intestinal hæmorrhage; but the condition of the heart seems to afford adequate explanation. The weakened heart, so long as no special stress was put upon it, continued to perform its function, but failed to respond to the additional strain involved in the administration of anæsthetics; and, as often happens with degenerated hearts, was afterward unable to recover itself, even with the aid of constant and thorough stimulation and of equally strenuous effort directed toward the dilatation of the superficial capillaries. The special seat of degeneration in the right ventricle, and the entire dependence of symptoms upon this seat of disease, may be regarded as peculiar. The primary failure of the pulmonary circulation was evident in the extreme and persistent cyanosis of the patient during the whole period of anæsthesia. With the discontinuance of anæsthetics the blood passed more freely through the lungs, and cyanosis for a time disappeared; but the ventricular contraction was still inadequate, and with the supervention of vomiting on the third day became still more incapable of transmitting blood through the lungs. Blood gradually accumulated in the right side of the heart, and secondarily in the inferior vena cava and portal system, till the over-distended gastro-intestinal vessels finally gave way. The resiliency of the lungs forced the last of the blood received through the pulmonary arteries into the left ventricle, which, less degenerate than the right, in turn forced it into the general circulation; and the left ventricle, like the lungs, was left empty and contracted. The final drainage of the pulmonary vessels of the lung was doubtless aided by the suction force exerted by an already approximately empty left ventricle.

The copious hæmorrhage emptied to a large extent the portal veins, the inferior cava, and the right ventricle.

A CLINICAL ANALYSIS OF DIGITALIS AND ITS PREPARATIONS, CALLING ESPECIAL ATTENTION TO THE GLUCOSIDES AND MORE ESPECIALLY TO DIGITOXIN.*

By LEON L. SOLOMON, A. B., M. D.,

LOUISVILLE,

PROFESSOR OF MATERIA MEDICA AND THERAPEUTICS AND OF CLINICAL MEDICINE IN KENTUCKY UNIVERSITY, MEDICAL DEPARTMENT; EX-CHAIRMAN MATERIA MEDICA, PHARMACY AND THERAPEUTICS SECTION OF THE AMERICAN MEDICAL ASSOCIATION; LECTURER ON MATERIA MEDICA AND THERAPEUTICS TO THE NORTON INFIRMARY TRAINING SCHOOL AND TO THE LOUISVILLE TRAINING SCHOOL FOR NURSES; PATHOLOGIST, LOUISVILLE CITY HOSPITAL, ETC.

IN the present state of our knowledge of the digitalis glucosides, there is a great diversity of opinion among authorities, and much confusion prevails in the minds of clinicians, regarding the several active principles of digitalis. It will not, then, be amiss for the writer to add his testimony to the great mass of literature on the subject, especially if he undertakes to bring, out of the existing chaos, some sort of order. As the title of this paper suggests, digitoxin has been chiefly considered, but other preparations of the foxglove had to be studied, in order that the relative strength of the former might be estimated, and comparisons have, of necessity, been made with the commoner preparations, such as the tincture, fluid extract, and infusion of digitalis; comparisons likewise have been made with the so-called "standardized and physiologically tested" powdered solid extract, and with the various digitalis glucosides, especially the digitalins. The physiological activity and relative strength of digitoxin was also estimated by clinical comparisons with the several strophanthus preparations, more especially, though, with the standardized tincture of strophanthus, which, from a clinical standpoint, is one of the most uniformly active preparations supplied us in recent years by pharmaceutical skill. Finally, the available literature on the subject of the digitalins, cumbersome and confusing as it all is, and the meagre literature on digitoxin, has been carefully reviewed and represents partly the information from which conclusions may be drawn at this time and in this paper.

There are several reasons for the present unsettled state of our knowledge regarding the digitalis derivatives, and these are, in the author's opinion, seemingly due no less to a meagre and unsatisfactory knowledge of the identity, virtue, and activity of the digitalis proximate principles, than to the faulty methods of isolating these principles, whereby their activity is lessened or destroyed; the rules, or lack of rules, governing the selection, gathering, and preservation of the plant digitalis, also deserves much of the blame. In fact, herein lies the great difficulty, which must be removed ere the digitalis problem is solved; and by this it is understood, that greater care must be exercised in the gathering of such plants as digitalis, not only as to the time of gathering, but also as to the selection of only true and perfect speci-

mens, and as to the best method for preserving the same; and more vigilance must be exercised in the *first* inspection and examination of the leaf offered for sale, before a purchase is made by the manufacturer. (*Note*.—It does not seem to be generally known that *young* leaves of the digitalis plant are worthless—containing little, if any, active principle—and that the best time to gather the leaves is during the period of blooming of the *second* year's growth.)

At last the crude drug, digitalis or other plant, in its simplest unchanged form, must be standardized by chemical assay or by approved physiological test, and the total of contained active principles then estimated. In the case of digitalis, since it is not uncommon for clinicians to prefer an infusion prepared *only* from the fresh recently dried leaf, there may be some reason why the plant had best be examined in its *fresh* state, and the total amount of glucosides estimated and removed before the so-called *odoriferous* principles have escaped—if, indeed, it is possible for the latter to be lost in a short time, or if these principles are really worth the attempt to save. Attention was called to the importance of such a procedure years ago, but, so far as can be learned, no action was ever taken in the matter.

Too much stress cannot be laid upon the methods employed to abstract any one or more of the active principles of a drug, and to the technique of separating and removing one from the other, where, as is commonly the case, several active principles are present in the same plant, lest the activity be mitigated or destroyed; for it is a well-known fact, how very delicate, as a rule, glucosidal and alkaloidal principles are. And, when a given principle is once isolated, let us be positive of its isolation in a state of absolute purity; let us know that it is, in truth, a "simple," and not a compound and complex, substance; let us indicate at the same time, if such indication is at all possible, the exact chemical formula for the active principle in question, and then, before the physiological action is studied, let there be undertaken certain tests for the determination of positive identification and purity, and let these latter also be established, on good ground and authority. An approved method, recognized by all those engaged in the isolation of the digitalis glucosides, and a standard article of standard strength with approved method for such standardization, would very much simplify matters and result in the greatest good for all mankind. As it is to-day, the digitalin of one make is often double and treble, and occasionally many times multiple the strength of another digitalin, prepared by a different manufacturer. Recently, a specimen came to my notice, the dose of which, as used by a colleague, varied between one and five grains. In dealing with an article at once so potent as the digitalins *may* and *should* be, it seems criminally dangerous for our science to tolerate inaccuracies of this kind; the permitting of such tremendous differences in the dose of any medicine, much more in active principles, is a sad

*Research work, department of materia medica, Kentucky University.

commentary on pharmaceutical, chemical, and mathematical precision; nor has there been, up to the present time, even a consensus of opinion as to the identity of the digitalis glucosides. French and German observers have invariably disagreed, and articles similarly named by them exert, in the clinician's hand, actions oftentimes widely differing. Different investigators in the same country—French, German or Italian—have likewise failed to agree among themselves. The fact that opinions not only do not coincide, but indeed greatly conflict, in the native sources of these products, makes it difficult for America, that does not manufacture, as a rule, such articles for her own consumption, to throw any light upon the subject, and we must continue to look to the source of the digitalis derivatives, for pharmaceutical chemistry to make conflicting opinions agree. It is to be hoped that the early future may soon see a definite, standard article—a digitalin of definite, standard strength—produced by any legitimate firm, it matters not whose label it bears. According to our present indefinite knowledge, the digitalis glucosides may be enumerated as follows:

1. Digitalin, pure powder—Germanic, or *digitalinum germanicum*, a yellowish, white powder soluble in water and alcohol, hardly soluble in ether and chloroform—obtained first by Schmiedeberg in 1874 and by him said to be a mixture, containing largely digitalein, by others said to contain some digitonin and digitoxin. The digitalin, German (Merck), is a more uniform product.

2. Digitalin, pure amorphous—so-called chloroformic digitaline or *Digitalinum gallicum*, Homolle's or Quevenne's digitaline, also called *Digitalinum amorphum*, a white or yellow powder, insoluble in water, soluble in alcohol and chloroform—contains chiefly digitalin and a little digitoxin. This preparation is identical with the digitalin of the *British Pharmacopœia* and with that in older editions of the *United States Pharmacopœia*; the process for the extraction of the same was removed in the 1880 revision, because of the indefinite product it yielded. In France, Homolle's digitaline is looked upon as an impure form of Nativelle's digitaline, and that manufactured in Germany, and called *Digitalinum amorphum*, is said by them to contain digitalein.

3. Digitalin crystalline—so-called *Digitaline française cristallisée*, or Nativelle's digitaline—a very active preparation; white, shining crystals, soluble in alcohol or chloroform, hardly soluble in water or ether, containing chiefly digitoxin and a little digitalin. Nativelle obtained the Orfila prize in 1871 for this digitaline. On account of its contained digitoxin, it has been advised, chiefly by the Germans, not to use it hypodermatically, fearing abscess; the fact that it contains digitoxin, no doubt, explains largely its activity. It produces no abscess.

4. Digitalin, true—Kiliani or so-called *digitalinum verum*, seemingly identical with the digitalein of Schmeideberg.

5. Digitoxin, a white, crystalline powder, soluble in alcohol and chloroform, slightly soluble in ether, insoluble in water; the most active preparation among the digitalis glucosides and the most prompt.

6. Digitophyllin of Kiliani, a crystalline substance resembling digitoxin, soluble in chloroform, not yet thoroughly understood; has the probable formula, $C_{32}H_{52}O_{10}$.

7. Digitalein, soluble in ether and in water and alcohol; an active cardiac stimulant.

8. Digitonin, readily soluble in water, sparingly in alcohol, is a direct cardiac depressant, resembling saponin, and is irritant to the stomach. It is the most active diuretic principle in digitalis.

9. Digitin, is therapeutically inert.

According to Fouquet, there are two groups or classes of digitalins, namely:

(1) Digitalins soluble in chloroform and insoluble in water.

(a) Crystalline digitaline.

(b) Amorphous digitaline.

(c) Digitoxin.

(2) Digitalins insoluble in chloroform and soluble in water.

(a) Digitalinum germanicum.

(b) Digitalein.

Of these two classes or groups, he advises the use of the first, and specially prefers, in this class, the crystalline digitaline. (*Note.*—It will be seen that this author counts digitoxin among the digitalins.)

Bardet affirms that amorphous and crystalline digitaline prepared in France are identical in their action, and that, according to the French *Codex*, both must be entirely soluble in chloroform, hence the appellation, "chloroformic digitaline," as applied by the French. However, Bardet also prefers the crystalline digitaline to the amorphous, because, as he says, it is "slightly more pure." The same author states that digitoxin, as marketed in Germany, is an indefinite mixture, incompletely soluble in chloroform, of variable activity, and only one half to one third as strong as the chloroformic digitalines. He asserts, furthermore, that German digitalin is not only variable in action, but is, in truth, only digitalein. Corin disputes these assertions on good authority, and H. C. Wood, Jr., and J. P. Arnold, in a contribution to the *American Journal of the Medical Sciences* for August, 1900, affirm that the digitalin, German, as prepared by Merck, is physiologically uniform in action and stable in its composition. Identical results were obtained by them with a sample two years old, and with a fresh sample, both from the Merck laboratory. My own clinical observations with digitalin, German (Merck), verify the results obtained by the two last-named experimenters. The product was found by me to be entirely uniform in its action, and, in a proper dose, from one twenty-fifth to one fourth of a grain, very reliable. As for digitoxin, it was found, contrary to Bar-

det's experience, to be soluble in chloroform, and instead of being only one third to one half as strong as chloroformic digitaline, it proved to be, in reality, from three to four times stronger. Indeed, the statements that digitoxin is the most active of all the digitalis glucosides, the most prompt, the most powerful, the most reliable in its composition and in its therapeutic effects, have all been abundantly realized in my hands.

The Choice of a Digitalis Preparation.

In the choosing of a preparation of digitalis, the profession is, as a rule, entirely too lax, and too indefinite an idea is ordinarily had of the work expected of the preparation in question. Among the several points which arise, when we are about to order digitalis, the following are most important:

1. Shall the effect be immediate or is only a slow result required?

2. Is a cardiac action chiefly desired?

3. Is a diuretic action chiefly desired?

4. Shall the action be both cardiac and diuretic?

The solubilities of the several digitalis principles are, as already stated, not identical, therefore the activity and virtue of a tincture (or a fluid extract) of the drug is not identical with that of an infusion, nor does either of these preparations represent the entire activity of the plant. In fact, but one preparation of digitalis does fully represent the drug, and this is the powdered leaves, which have the most irritant effect on the stomach of all the digitalis preparations. The Swiss preparation, known as the "dialysate of digitalis," is made by a special dialyzing process of the freshly plucked leaves with water and alcohol—each part by weight of the "dialysate," it is stated, corresponding exactly to a part by weight of the plant. The last-named preparation is said to be very active and reliable. In the tincture, as well as in the fluid extract, on account of their solubility in alcohol, digitalin and digitoxin chiefly preponderate, but there are found also some digitalein and digitonin in these two preparations. The action is therefore chiefly cardiac and slightly diuretic. The infusion containing little, if any, digitalin or digitoxin, but considerable digitonin, as well as some digitalein, is the best diuretic preparation of digitalis. In prescribing the tincture, it is well to remember that the addition of water modifies the virtue of the preparation by precipitating the contained digitoxin. If water is taken with the dose, any precipitate that settles to the bottom should be swallowed. It is best to exhibit this preparation in capsule.

Physiological Action.—The pharmacodynamics of digitalis is very well understood, but the writer, in reviewing several features representing the different actions of the various digitalis derivatives, desires to call attention to certain fallacies, which seemingly go unnoticed, in the ordinary measures and technique adopted to ascertain the physiological action of any drug. It has been the custom in previous years to study the cardiac

action of digitalis, for instance, upon the heart of the frog; more recently, in attempting to standardize physiologically the drug in question, it has come to be the custom to employ for experimental purposes the dog or some other one of the lower animals—in the case of ergot, the fowl is used (the comb of the cock). There can be no doubt that the employment of warm-blooded animals or fowls for these purposes has much to commend it over the use of the batrachian, since, with the latter, the results are open to argument on the ground of the considerable difference in the histological framework of organs and tissues, to say nothing of the wide variance between the central and sympathetic nervous systems of the two subjects employed. But this is not the only point, nor, in the writer's opinion, is it the important point, to which especial attention will now be attracted. Under such circumstances, conclusions concerning pharmacodynamics are reached with experiments upon animals or fowls *invariably* in a state of more or less perfect health; and these conclusions are intended to afford the student and practitioner of medicine a definite idea of the action to be expected from the same drug, when administered in the same dose to a human patient—the latter, presumably, an individual with deranged secretions and in a pathological state. In other words, from the effect obtained by the administration of one fourth of a grain of morphine sulphate, for instance, to a healthy dog (or even to a healthy man), we are left to gauge the probable effect that will be obtained when the same dose of one fourth of a grain is administered to a person suffering, let us say, from renal colic; or, if to a third individual in shock, the identical drug in identical dose is given, the effect awaited is to be judged by the original effect observed in the case of the dog (or man) in health. If it is urged that these principles do not represent a true guide for the estimation of drug action, I reply that the premises then are always false upon which such judgment is based, and the text-books mislead us. According to our books and to the manner of calculating physiological action, doses of one thirtieth of a grain of mercury bichloride, given three times daily for one week, would have the same effect in the case of a healthy dog or healthy man, as the same dose of the same drug has in the case of a patient suffering with secondary syphilis; or a thirty-drop dose of fluid extract of ergot must act identically in the case of *postpartum* hæmorrhage, as it does on the bright red comb of a healthy young brown leghorn hen. Examples of this sort might be multiplied almost *ad infinitum*, and the conclusions are invariably reached along false lines. Drugs can only be studied, and pharmacodynamics only estimated, by a consideration of their influence as exerted in diseased states; and, when such a method of determination is once adopted, as it surely, sooner or later, must be, then the name, "physiological action," will cease to exist, as it properly deserves.

Digitalis is no exception in these respects, as the experiments of Czyhlarz have abundantly proved; with

Gaertner's tonometer he demonstrated the failure of a fixed amount of standardized digitalis (using the infusion) to raise the blood pressure or to increase the amount of urine in persons with normal circulation, the same infusion producing, without exception, these effects where cardiac trouble existed. In other words, all drugs have more or less so-called specific or "selective" action in disease—which often varies in the case of the same drug in different diseases—and no manner or variety of experiments upon the lower animal or upon the fowl *in health* could ever develop such true action. Twenty-five and fifty years ago, clinicians were in the habit of giving very large doses of infusion of digitalis to persons suffering with croupous pneumonia. It was found, then, that these cases were benefited by heroic quantities of the infusion—such amounts as people in health or those suffering from other affections than pneumonia could not tolerate. The reason was at that time unknown, but we readily see it to-day; since, according to Maragliano, digitalis actually neutralizes the toxine produced by the pneumococcus. This fact he has established, seemingly beyond the peradventure of a doubt, as follows: One centigramme and a half of digitalin are added to ten grammes of a pure culture of the pneumococcus, whereby the latter are killed; Maragliano affirms that as little as three milligrammes of digitalin, added to a ten-gramme culture of pneumococci, hinders their development. This action is "selective" or "specific" in the case of pneumococci alone, it having been found that digitalin will exert no such influence over the culture of other germs.

Indications and Contraindications.—We are taught that digitalis is indicated wherever there is failure in the dynamic power of the heart muscle, especially if, at the same time, arterial tension is low; but it is surprising—and this point must be emphasized—what benefit follows the administration of the drug in cases where, on theoretical grounds, consensus of opinion would advise us "best to avoid it." This not infrequently happens in aortic regurgitation. Again, great vascular excitement, high arterial tension—the latter as found in chronic nephritis—and existing hypertrophy of the heart, provided it is complete, contraindicate digitalis; the nitrates, under such circumstances, make an admirable addition to the drug, especially nitroglycerin, which, obviating arterial constriction, often permits of the use of digitalis when it would otherwise be impossible to exhibit it. A course of iodine—potassium or other iodide—preceding the digitalis or accompanying its administration, has been found highly satisfactory in some cases, especially, where the drug is contraindicated in arteriosclerosis; in the latter condition, high vascular tension sooner or later disappears, and then digitalis will serve its usual good purpose. In the issue of *Therapie der Gegenwart* for March, 1900, is reported the account of an autopsy on a middle-aged man; the report is of present value: Cor bovinum, moderate stenosis of ostium aorticum, aortic aneurysm, arteriosclerosis of kidneys—and

notwithstanding the existence of these conditions (any one or all of which would ordinarily contraindicate digitalis) the patient had been kept "comfortable, in fact, in good health," for a period of eight years by the daily administration of from one and a half to two and a half grains of the powdered drug. During these eight years, it is calculated that the patient took something less than ten ounces of digitalis. His death was sudden, following an unusual physical exertion.

Cumulative Action.—This may be entirely avoided by carefully watching diuresis and by diminishing the dose or exhibiting the drug at longer intervals, say, once in twenty-four hours; occasionally, it is well entirely to skip a dose or two. For long-continued use, it is proper to give a diuretic with the digitalis periodically; in this respect it may be well to remark on the usefulness of calomel in combination with digitalis. In the *Practitioner* (London) Groedel says that cumulation is due to too large doses given after too short intervals, and he attaches the blame to the physician's hurry to obtain an effect without proper regard for elimination. It is well to bear this in mind.

Relative Cardiac and Diuretic Action of the Digitalis Derivatives.

Digitin, being therapeutically inert, will not be considered.

Digitonin is a direct cardiac depressant, resembling saponin, and, like it, directly antagonizing the cardiac action of digitalin, digitalein, and digitoxin, by depressing the vagus centrally and peripherally. It is the most active diuretic principle among the digitalis glucosides, as already mentioned; but it irritates the stomach very much.

Digitophyllin has been used to a very limited extent. Its action resembles that of digitoxin; like the latter, it is prompt and energetic and may, some day, enjoy wide use.

On the heart, and on the circulation in general, the three digitalis glucosides, digitalin, digitalein, and digitoxin, have effects much in common. There are, however, certain well-defined differences, which will shortly be outlined. All three can be called true heart stimulants, acting directly upon the heart muscle, making the pulse stronger and firmer; but digitalin stands alone and is unique because of its *special* influence upon the vasomotor centre, on the medulla, and upon the ganglia in the muscular coat of blood vessels, contracting the blood vessels and thereby raising arterial pressure. Digitalin also slows the pulse, by directly stimulating the cardiac ganglia (acting upon both the roots and the ends of the vagus). Digitalein and digitoxin do not directly raise arterial tension, nor do they directly slow the pulse. Professor Kobert has demonstrated, however, that both of the latter *dilate* renal blood vessels, increasing the flow of urine, and this action makes these two principles also unique, greatly enhancing their therapeutic virtue and value. It has already been stated that the diuretic action

of digitalis is best exhibited in cardiac affections accompanied by low arterial tension. In a healthy state of the heart and circulation, diuresis is usually wanting.

And now we have come to the most important part of our subject, namely:

Digitalin and Digitoxin Contrasted.—This study was made with Merck's digitalin, German, and digitoxin, Merck. The formulæ digitalin $C_{35}H_{56}O_{14}$, and digitoxin $C_{34}H_{54}O_{11}$, are now pretty definitely established, though not absolutely so.

Digitalin, German-Merck, is a yellowish-white powder, soluble in alcohol and water; almost insoluble in ether and chloroform.

Digitoxin—Merck—is a white, crystalline powder, insoluble in water, but soluble in alcohol and chloroform, and slightly so in ether.

Dose: Digitalin, from one twenty-fifth to one fourth of a grain; digitoxin, from one one-thousandth to one two-hundred-and-fiftieth of a grain, up to one fortieth of a grain daily (regarded as the maximum quantity of the latter.)

Digitoxin is the chief ingredient in the leaf of the foxglove, and the latter should, in the author's opinion, be standardized in terms of its contained digitoxin. By means of ether, digitoxin may be obtained and removed from an extract of the leaves. Contrary to Schmiedeburg's statement that digitoxin is *not* a glucoside, it is possible by means of heat, in the presence of an alcoholic solution of hydrochloric acid, to split up the digitoxin into digitoxose and digitoxigenin.

As a diuretic, digitoxin is superior to digitalin, since it actually dilates the renal vessels, while stimulating the heart. Furthermore, its action is prompter and more certain than that of digitalin. It manifests its effects oftentimes within twelve hours, and is less liable to cumulative action than digitalin. Because of the uniformity of its action and of its energy and strength, no doubt, digitoxin has the brightest future of all its sister glucosides. Masius, who has employed it considerably, styles the action "certain, quick and energetic." He has used as much as one fortieth of a grain a day. Heger believes that the action of digitoxin is chiefly on the left ventricle. Van Aubel classes it as "the most prompt, reliable, and powerful derivative of digitalis." After discontinuing the use of the drug, the influence of digitoxin is said to persist, sometimes, for from eight to ten days. Under Professor Unverricht, in the Municipal Hospital of Magdeburg-Sudenburg, Wenzel has experimented with the drug and declares it to have been useful in certain cases where other preparations, including the infusion, had failed. To avoid digestive disturbance, Wenzel employed it chiefly by enema, giving about one eightieth of a grain in ten minims of alcohol and four ounces of water. The action upon the heart, as observed in these experiments, was quite pronounced; at first, three rectal injections were given daily (previous thorough cleansing of the bowel being presupposed); afterward, only two

injections were used; and, finally, only one was found necessary, in order to maintain the first effect produced. In my own hands, digitoxin has been given in a series of cases—of late, chiefly hypodermatically, but also by the mouth (*always after meals*). It was the exception to see any digestive disturbance when one five-hundredth of a grain or less of digitoxin was being given, three times daily; digitalin, however, not infrequently had caused, in my hands, some such unpleasant accessory effect. (*Note.*—The action of the smaller doses of digitoxin has been so satisfactory that I have not had occasion, in the majority of instances, to employ more than one five-hundredth of a grain, and never over one two-hundred-and-fiftieth of a grain.) In no case did an abscess ever result from the hypodermic syringe. A very hard infiltration œdema usually followed the injection, until, after many pricks of the needle, the tissues about the point of puncture became stiff and rigid, interfering somewhat with the function of the part (as about the arm or leg). Pain was almost invariably complained of when the medicine was given by this route, but it never continued long. If the arm was being used, it would become tender, and, from the great amount of infiltration for the time being, function would be modified. However, these symptoms and signs disappeared promptly with the withdrawal of its administration by this route. I am aware my experience in several ways does not coincide with that of Messrs. Wood and Arnold, who find the drug too irritating for administration by the mouth, and report it as liable to cause abscess when injected hypodermatically. Mr. Fowler, a local chemist and experienced tablet manufacturer, prepared the drug for me in hypodermatic form; at first tablets of $\frac{1}{1000}$ th of a grain, later $\frac{1}{500}$ th of a grain. By the mouth, the cardiac action was not so pronounced as when the drug was thrown under the skin. Under any circumstance, however, it mattered not by what route digitoxin was introduced, there was invariably an effect of which, not only doctor, but often patient as well, was aware, digitoxin being an agent the influence of whose action is a perceptible one; one patient, an elderly lady with myocarditis, who suffers recurring attacks of tachycardia and whose vitality is often at a low ebb, describes the action as "sustaining," and says that her strength is always re-enforced by the dose. It was sometimes observed that the bowels were relaxed while digitoxin was being taken, this chiefly occurring when the dose was exhibited by the mouth; however, laxative action was by no means the rule.

It having been urged that digitoxin in solution is likely to become insoluble on coming in contact with the fluids of the body, I have never attempted until lately to give it in solution, except in hypodermatic solution (dissolving one or more tablets in thirty minims of water), as already stated. A solution prepared for me by a local pharmacist and intended to be used internally—dose, one teaspoonful—without instructions as to how he should prepare it, contained fifty per cent. of alcohol; this was

thought not only too much alcohol for the good of the stomach, but the solution precipitated when water was added; besides, it was feared that the alcohol might influence the cardiac action of the digitoxin; certainly, such a danger would not be insignificant if a solution of similar alcoholic strength was employed hypodermatically.

Where high tension existed, the combination of digitoxin with nitroglycerin acted admirably.

Uses.—Digitoxin has been especially recommended in chronic myocarditis and in cases of ruptured compensation. The following brief notes, taken at random from my history book, will illustrate the variety of purely cardiac and related conditions in which the drug has been employed by me:

CASE I.—L. R., a young man aged twenty-three years, came under my observation in July, 1898 (during the absence of his physician), with a history as follows: Single; occupation, bookkeeper and collector; diagnosis, mitral regurgitation, compensation ruptured. Patient was suffering with dyspnoea, cough, a prune-juice sputum, cyanosis, œdema of the lower extremities, urine half a pint in twenty-four hours. Doses of $\frac{1}{1000}$ th of a grain, later increased to $\frac{1}{500}$ th of a grain of digitoxin, were administered four times daily by the mouth. The urine was much increased in twelve hours; it was doubled in twenty-four hours, and in another twenty-four almost a quart was passed; the cyanosis disappeared and with it the cough. After two weeks the patient was able to be up and about, and, in another week, to begin work (walking, as a collector, necessary). In several succeeding attacks, in which I saw him, the drug was just as effectual in relieving symptoms.

CASE II.—Mrs. M. B., school teacher, aged forty-one years, addicted to the use of strong drinks and a morphine habitué, came to see me in March, 1897: Diagnosis, chronic interstitial nephritis, with myocarditis. Digitoxin, $\frac{1}{1000}$ th of a grain every four hours (five doses daily), was ordered. The shortness of breath, palpitation, and præcordial distress and headache disappeared after one week.

CASE III.—Mrs. B., aged sixty-three years. Diagnosis, mitral regurgitation of two months' duration, following acute articular rheumatism; compensatory hypertrophy had not occurred. The patient was referred to me from her home in the country. The condition was criticized on account of pulmonary œdema, pleuritic effusion, and almost entire suppression of urine; there were general anasarca, obstinate nausea and vomiting caused by acute parenchymatous nephritis. Doses of $\frac{1}{500}$ th of a grain, increased to $\frac{1}{250}$ th of a grain, of digitoxin by the mouth were retained; the diarrhoea which occurred was thought to be a natural sequence from defective kidney elimination and not due to the digitoxin, although the drug had relaxed the bowels in other cases. The volume of the pulse improved and the pulmonary signs disappeared after three days. The kidney action was the most prominent feature in this case, the quantity of urine reaching one litre and one fourth by the end of the week. The patient soon thereafter left her bed, compensation having been very satisfactorily established.

CASE IV.—Mr. M. F., aged seventy-five years, retired merchant; diagnosis, acute ulcerative colitis, ar-

teriosclerosis with high-tension pulse; was seen by me through a long illness during which the bowel trouble assumed a chronic type and the danger of death by cardiac asthenia became evident. The administration of digitoxin $\frac{1}{500}$ th of a grain, with nitroglycerin $\frac{1}{100}$ th of a grain four times daily, was begun. The result was prompt and wholly satisfactory. The patient recovered, was once more able to appear on the streets, and lived over eight months.

CASE V.—Mrs. R. D. A., aged seventy-two years. Diagnosis, myocarditis with frequent attacks of tachycardia. This lady has chronic interstitial nephritis. She was given digitoxin continuously for several months as a substitute for digitalin, which had been taken previously, and for years; the paroxysms of tachycardia grew very much less frequent, and the lady, who is intelligent and watches the effect of drugs closely, declares that there is a "sustaining" influence noticeable as soon as she takes digitoxin. (This case has already been referred to in this article.)

CASE VI.—Mrs. J. F., aged forty-three years, widow, has been leading a very inactive and indolent life for the past three years, causing the accumulation of much surplus adipose tissue. Diagnosis, fatty infiltration of the heart; dyspnoea was complained of upon the slightest exertion, and attacks of syncope were of almost daily occurrence. Digitoxin was employed, $\frac{1}{500}$ th of a grain every four hours (five doses daily), and massage with a modified plan of the "Schott method" of resisted movements and baths. The action of the digitoxin upon the heart and kidneys was perfect, recovery being complete within three months.

CASE VII.—Mrs. A. L. L., aged twenty-six years, housewife. Diagnosis, asthma, cardiac in nature. Irregular, feeble pulse, more or less constant dyspnoea, very much exaggerated during the frequently recurring paroxysms, loss of flesh and strength, palpitation. The severity of this patient's asthmatic attacks can best be judged by the statement that morphine did not relieve them, nor did the inhalation of chloroform or ether, pushed to the obstetrical stage. It was found that digitoxin invariably controlled the paroxysm. The patient was put upon a liberal diet, and tonics, in conjunction with Buffalo Lithia water, completed relief from the disease, which has not reappeared now in at least six months.

CASE VIII.—A. M., aged fifty-six years, minister. Diagnosis, Parkinson's disease. Upon his return from a certain health resort, he was found to be suffering from acute bromism, the result of the prolonged use of large doses of the mixed bromides. There was a tendency to depression of spirits with sudden bursts of emotion. The patient became angry upon slight provocation, and would cry even when the provocation was less. The pulse was feeble and fast. The first dose of digitoxin, $\frac{1}{500}$ th of a grain, given hypodermically at 5 P. M., after an attack of syncope (precipitated most likely by the thought of his inability to begin work the following day), had a remarkable effect. The patient in a half hour was up and had dressed, insisting upon going to the barber's shop, although his gait had been unsteady and tottering, and much weakness had been complained of one hour previously. The walk to the barber's shop, some three blocks distant, was made without difficulty, and later he sent me word that the "sustaining" influence of the drug could still be clearly felt. One five-hundredth of a grain, four times daily, hypodermatically, was continued for two weeks, the cardiac asthenia entirely disappearing and the

psychical condition of the patient undergoing salutary change as well.

CASE IX.—Emil W., aged seventeen years, tailor's apprentice. Diagnosis, dilated right heart. A frail lad closely confined, running a machine in a contract sweatshop. I had treated him for some three years or more for a stubborn malarial cachexia. While climbing a steep hill on his bicycle one Sunday morning, the patient suddenly felt an agonizing pain in his cardiac region. His "breath came short and quick," and he fell from his wheel. I saw him the same morning; dyspnoea was marked, there was cough and frothy, blood-stained expectoration, the pulse was exceedingly feeble, but *slow*. Physical exploration made out a dilated right heart. Rest in bed, nutritious diet, and digitoxin $\frac{1}{500}$ th of a grain every three hours, constituted the treatment. On the second day, the interval between doses was increased to four hours, and, after two days, three doses daily of the digitoxin were administered, the symptoms justifying this infrequent exhibition of the medicine. Within two weeks, the cardiac measurement was normal and the patient has experienced no further trouble.

CASE X.—Mrs. S., aged twenty-eight years, member of the demi-monde. Diagnosis, mitral regurgitation. The patient had been an inveterate smoker of cigarettes, and otherwise was leading a riotous life. She suffered attacks resembling pseudo angina pectoris and had been unable to lie down or to sit down for the most part of the day when I saw her. Inhalations of amyl nitrite were practised, for the paroxysm, and the patient was put on digitoxin $\frac{1}{500}$ th of a grain every four hours, later increased to $\frac{1}{250}$ th of a grain. The attacks became less frequent, and the patient enjoyed several months of complete freedom, finally dying suddenly while in bed, after I had dismissed her from immediate care.

CASE XI.—Mr. R. W., aged twenty-five years, street railway motorman, suffering with typhoid fever. Strychnine had been employed, during the latter weeks of the disease, and continuously after convalescence had otherwise been well established, but the pulse continued to run up twenty to fifty beats per minute upon the slightest exertion, and severe palpitation with præcordial distress would then be experienced. The strychnine was discontinued, and four tablets of digitoxin ordered daily (grain $\frac{1}{500}$ th). Within twenty-four hours the patient felt better, and, after three days, was able to walk half a mile without palpitation or much increase in the pulse rate. On the ninth day he was dismissed, having then completed his thirty-sixth tablet of digitoxin. He was able to leave with his gun on a hunting expedition.

CASE XII.—Mrs. J., aged forty-one years, widow, professional hairdresser. Typhoid fever in 1897, treated by me. Since then, dyspnoea upon exertion; the patient leads a very active, outdoor life; nevertheless, she has taken on flesh steadily. She complained of palpitation and darting pains through the region of the heart. Recently, I was summoned to find her extremely dyspnoeic, with pulse 120, soft and compressible. There were cough, numerous dry and some moist râles, and slight expectoration. The patient thought she was entering the climacterium and that this explained her present indisposition. In order to make a comparative test of the cardiac activity of drugs, in this case, strychnine was first employed (after controlling the paroxysm with a morphine injection). There being no appreciable influence upon the quality of the pulse by the fourth day of its administration, digitalin was substituted, followed after another three days, because of lack of effect, by the infusion of

digitalis, but this did not slow the pulse rate. Finally, digitoxin was administered in $\frac{1}{500}$ th of a grain doses. The effect was prompt and entirely satisfactory, the pulse becoming fuller and stronger.

CASE XIII.—Miss C. S., aged fifty years, school teacher, with aortic stenosis. Compensatory hypertrophy, originally complete; every spring, for the past six or eight years, patient has had to take heart tonics. During the three previous years, she has been under my care, and on each occasion infusion of digitalis was prescribed for the first few days, and, when the stomach rebelled, was followed by ten-drop doses of tincture of digitalis, four times daily, in capsule. Even under the latter preparation the stomach rebelled and the appetite waned, until, as was the rule, anorexia became complete. Last April, Miss S. again consulted me. Digitoxin was this time prescribed, $\frac{1}{500}$ th of a grain four times daily. The effect was prompt, salutary and *benign*, there being no gastric disturbance. To use her words, "Digitoxin marks a real advance and is a boon."

CASE XIV.—Mrs. J. S., aged forty-two years. Diagnosis, typhoid fever. During the first week of the disease, the pulse was 110 and dicrotic. Digitoxin had a remarkable effect in this case, not only sustaining the hypodermic injection of $\frac{1}{500}$ th of a grain had a quieting pulse, but when the patient was restless and fretful, the influence upon the nervous system as well. In fact, the action was very similar to that of morphine as we see it in shock.

It seems unnecessary to recite other examples. In the accounts, already given, which have been taken at random from my records, a very fair idea may be had of the certain results obtainable with digitoxin. Until a more definite product is supplied by the various manufacturers under the generic name of digitalin, the former must continue to grow in favor and finally supplant the latter, and, as the profession becomes better acquainted with the virtue of the article, digitoxin seems destined to enjoy the widest range of usefulness and popularity.

Note.—A solution of digitoxin, we are told, is liable to precipitate on coming in contact with the secretions of the body. To avoid this, and yet not use too much alcohol in the pharmaceutical preparation of the solution, it has been recommended to add a little chloroform to the solution; several formulæ have already been worked out. The following solution has, after experimentation, been found to be stable and will not precipitate upon contact with blood serum, water, or sodium chloride solution:

℞ Digitoxin. $\frac{1}{250}$ th of a grain;
Chloroform. 1½ minims;
Alcohol at 90 per cent. 23 minims.
Water sufficient to make ½ an ounce.

M.

SECOND STREET AND ORMSBY AVENUE.

Physicians Demand a Living Salary for Health Officer.—The doctors of Marinette, Wis., recently passed resolutions asking that the salary of the health officer be raised by the city council from \$200 to \$1,000, and that that official be named by the physicians. All the physicians have pledged themselves to decline the office unless this is done.

AMÆBIC ABSCESS OF THE LIVER,
WITH A
REPORT OF FOUR CASES.

By FIRST LIEUTENANT C. R. DARNALL,
ASSISTANT SURGEON, UNITED STATES ARMY.

SINCE the American occupation of the Philippine Islands, Puerto Rico, and Cuba, the members of the army medical service have, for the first time, been brought into intimate contact with many diseases peculiar to tropical and subtropical climates. Some of these affections recent arrivals escape for a time, either because of vigorous health at the time of arrival, or because of special care being taken to avoid them. However it may be, it has long been observed that foreigners may enjoy excellent health for a year or eighteen months, and then, being more or less enervated by the climate, become the victims of such diseases as psilosis (sprue), amœbic dysentery, or amœbic abscess of the liver. For a considerable time amœbic liver abscess was rarely found among the cases in our military hospitals, but it has become more and more frequent until now it is quite common.

The cases reported below have all been received on the *Relief* since July 22, 1900. Besides these four cases, one other was found in the postmortem room during that time, in a patient dead from amœbic dysentery.

CASE I (U. S. army hospital ship *Relief*, Register No. 2303).—I. P. M. S., bandsman, Fourteenth Infantry, U. S. army, a native of Denmark, aged thirty-two years. Original admission to sick report, June 17, 1900. Admitted to U. S. army hospital ship *Relief* July 22, 1900, at Nagasaki, Japan, from U. S. army transport *Indiana*.

History.—Had been in excellent health until present illness began. Had been in Philippine Islands since August, 1898. Before that time had always lived in a cool climate. In April, 1900, he began to have a slight diarrhœa, which, growing steadily worse, became in a short time dysenteric in character. In May he noticed pain and tenderness over the liver and in the right shoulder and was more or less feverish in the evening. About this time he also began to lose flesh. He was first admitted to his regimental hospital in the latter part of June. He states that under treatment his dysenteric symptoms improved somewhat, and he was allowed to start with his regiment on the expedition to China. On arriving at Nagasaki, however, he was too weak to go farther and was transferred to the *Relief*.

On admission to my ward on the *Relief* he was found to be much emaciated, weighing only ninety-two pounds, his normal weight having been one hundred and forty pounds. Pulse, small, compressible, and about 100 a minute. The active dysenteric symptoms were somewhat in abeyance, the evacuations numbering three or four in twenty-four hours. The stools were of a light slate color, of a pultaceous consistence, and were streaked with mucus containing large numbers of very active *Amœba coli*, but no blood.

Temperature irregular, usually nearly normal in the early morning, and about 103° F. in the evening. There was marked enlargement over the right hypochondrium. The liver extended from the fifth rib in the right nipple line to two inches below the costal border. There was

much tenderness over the liver. This was particularly noticeable when pressure was made in the intercostal spaces. He had pain over the liver on coughing or taking a deep inspiration. Had slight dry cough.

Examination of urine was negative in result. Examination of blood showed diminution of red cells to 3,600,000 per cubic millimetre. There was a slight leucocytosis.

On making an exploratory puncture, pus was found in the convexity of right lobe. I operated on July 24th, resecting two inches of the eighth and ninth ribs between the anterior axillary and nipple lines. The limitation of the pleural cavity was found, and a trocar and cannula passed through the diaphragm below it into the abscess. The opening was then enlarged with a forceps and about two ounces of chocolate-colored pus evacuated. The abscess cavity was then washed out and a rubber drainage tube introduced. The wound was packed with iodoform gauze and dressings applied.

From the large amount of the subsequent discharge I am inclined to think that there were two abscesses in this case, only one of which was opened at the time of operation, the other rupturing into the first subsequently.

The temperature fell but little during the week following the operation, but gradually declined after that time. In scrapings from the abscess wall I found numbers of *Amœba coli*. The patient made an uneventful recovery. On September 13th, seven weeks after operation, the wound had entirely healed, there was no pain or elevation of temperature, and he was rapidly increasing in weight, having gained fourteen pounds since September 1st.

CASE II (U. S. army hospital ship *Relief*, Register No. 2326).—J. V. F., bandsman, Fourteenth Infantry, U. S. army, a native of Iowa, aged thirty-five years. Admitted to sick report August 2, 1900. Admitted to *Relief* from U. S. army hospital at Tientsin, China, August 16, 1900. Diagnosis on transfer slip: Acute pleurisy, right side (August 13th, effusion).

History.—He landed in the Philippines in August, 1898. Before that time he had always lived in a cool climate. During the time he was in the Philippines he had been in excellent health. Had never been on sick report nor had he ever had even a mild diarrhœa during that time, his bowels being always perfectly regular. He left Manila about the middle of July with his regiment for China, where he arrived July 27th. After being in China a few days he began to have pain in the right side and right shoulder. He stated that at times the pain in his side was excruciating. He located the pain over the convexity of the liver. He had slight fever in the evening and severe sweats at night. His bowels during this time were constipated.

When admitted to the *Relief*, on August 16th, he was considerably emaciated, the skin sallow, the pulse rather weak, compressible, and about 90 a minute; appetite good, no nausea, bowels constipated. Pain over right hypochondrium, aggravated by coughing or deep inspiration, also pain in right shoulder. Temperature ranged from 99° F. to 103° F. in evening. Severe sweats at night, or even in daytime when asleep; slight hacking cough; liver much enlarged, particularly upward and to the right. There was considerable bulging of the right side of the chest. The intercostal spaces were not obliterated, but there was much tenderness on pressure over them.

Blood examination showed slight leucocytosis. On August 18th, suspecting abscess of the liver, I made a number of exploratory punctures with a large needle in

various parts of the right lobe, but did not succeed in locating the pus. On August 22d the patient was seized with a paroxysm of coughing and expectorated large amounts of pus. He continued to expectorate some pus every day, but the amount varied considerably. I demonstrated the *Amœba coli* in the material expectorated. The rupture of the abscess into the lung had a slight, but not marked, effect on the temperature, and no effect whatever in the way of improvement in the general condition. His emaciation and weakness gradually increased. His condition did not admit of an operation, but his breathing became so labored and the distress so great, that, on September 18th, I made a small incision into the most prominent part of the swelling, under local anæsthesia, and evacuated 1,000 cubic centimetres of pus. This procedure relieved his sufferings, but he grew gradually weaker and died on September 25th.

Autopsy.—Emaciation extreme; skin and conjunctiva slightly jaundiced. There was about six ounces of a straw-colored fluid in pericardium. Liver much increased in size and both right and left lobes were adherent to the diaphragm. The right lobe was the site of two immense abscesses. One of these, situated in the convexity and extending upward and backward, had ruptured into the right pleural cavity, forming a large abscess at the base of the lung. The opening in the diaphragm was about two inches in diameter. The other abscess of the right lobe involved the under surface and anterior border. It was this abscess that I opened on September 18th. There was no communication between these abscesses. The left lobe was the site of a third abscess still intact and containing about 1,500 cubic centimetres of pus. There was merely a thin covering of liver tissue about this abscess, the whole interior of the lobe having been destroyed. The walls of all these abscesses were composed of partly destroyed liver tissue, and presented an irregular, shaggy appearance.

The kidneys were normal. The left lung was slightly œdematous at posterior part. The intestines were apparently normal. There were no evidences of dysentery, either recent or remote. I was unable to find amœbæ in the stools of this patient, though I made several examinations.

CASE III (U. S. army hospital ship *Relief*, Register No. 2481).—I. D., Troop A, Sixth U. S. Cavalry, a native of Massachusetts, aged twenty-two years. Admitted to *Relief* September 9, 1900, from U. S. general hospital, Tientsin, China. Diagnosis on transfer slip: Acute diarrhœa.

History.—Had been in good health until about a month previous to admission. He gave an obscure history of an attack of dysentery about a year ago, while living in Idaho. Had never been beyond the borders of the United States until he came to China in the latter part of July of the present year. For a month previous to admission he had been having diarrhœa, the evacuations consisting principally of undigested food, mucus and blood. He stated that he had much pain and tenesmus.

On admission to the *Relief* he had tenderness over the abdomen, frequent stools mixed with blood and mucus, a temperature of 102° F. and a pulse of 88.

On September 10th, I examined his stools and found enormous numbers of *Amœba coli*: urine normal; examination of blood showed moderate leucocytosis. The tenderness over the abdomen increased, particularly over the right upper quadrant. There was progressive emaciation. His temperature showed a diurnal variation of

about three degrees, the maximum being 103° F. Acting Assistant Surgeon Paul G. Hutton, under whose care the patient was at this time, made a diagnosis of suppurative hepatitis, and the patient was transferred to my ward on September 15th. On examination, I found marked tenderness over the liver, which was enlarged in all its dimensions. There was pain in the right shoulder and also pain over the liver on deep inspiration. There was marked bulging of the lower part of the chest on the right side. Severe pain was produced by pressure over the epigastric region, and by pressure over the lower right intercostal spaces. The patient's general condition was bad. I made an exploratory puncture on the 15th in the right anterior axillary line between the eighth and ninth ribs, and found fluid of a smoky chocolate color, mixed with some thicker yellow material. The patient immediately prepared for operation, which I did on the same day, assisted by Dr. Hutton. I resected three inches of the ninth rib in the right midaxillary line, and upon arriving at the pleura I found the costal and diaphragmatic portions firmly adherent over the site of the abscess, into which I made a free incision through the diaphragm. About three pints of a grumous, shreddy, cream-colored material, mixed with a thin coffee-colored fluid, were evacuated. The walls were then curetted and the abscess cavity washed out and drained with tubing and lightly packed with gauze. The discharge for the next day or so was quite free, but then lessened rapidly. The average temperature was reduced only about one degree by the evacuation of the pus. The discharges from the bowels (ten to fifteen in number daily) continued in spite of all treatment. The patient's condition grew steadily worse, death taking place on September 21st, six days after operation, from asthenia.

Autopsy.—On opening the abdomen there were found evidences of an old local peritonitis confined to the left side. The descending colon was firmly tied down by old adhesions throughout its extent. This part of the colon was very small, not so large, in fact, as the small intestine. I think it very probable that during the attack of dysentery, which he stated that he had a year ago, there was a perforation which caused the local peritonitis that produced the adhesions. There were found on opening the colon, inflammation and ulceration throughout its extent, most marked, however, in the descending portion. The mucous membrane of which was practically destroyed. These ulcerations, mostly circular in form, varied in diameter from five millimetres to three centimetres. Many had destroyed all the structures down to the peritoneal coat which was inflamed over them. The small intestine appeared to be normal. The liver was much enlarged and was adherent to the diaphragm over the site of the abscess. The latter, situated in the convexity of the right lobe, presented a large cavity with irregular projections from its walls. The walls consisted of a yellowish-white broken-down liver tissue gradually shading externally into the normal. Amœbæ were in the material scraped from the walls. The abscess was single, the remainder of the liver tissue being apparently normal. The gall-bladder was rather smaller than usual and contained a few drachms of normal bile. There were adhesions between the pleura over the base of the right lung and on the diaphragmatic pleura over region of abscess. There was hypostatic congestion of the posterior part of both lungs. The pericardium contained about six ounces of straw-colored serum. There were no other evidences of pericarditis.

CASE IV (U. S. army hospital ship *Relief*, Register No. 2526).—H. B. S., clerk, Quartermaster's Depart-

ment, U. S. army, aged thirty-two years, native of New Jersey. Admitted to U. S. army hospital ship *Relief* at Nagasaki, Japan, September 22, 1900.

History.—Health had always been excellent until going to the Philippines in April, 1899. He was perfectly well until April, 1900, when he had, as he stated, an attack of "malaria." He had fever at this time, slight in character, as he was able to continue his duties. About May 1, 1900, he began to have pains over the right side and in the right shoulder. He also began to lose weight about this time. In June his fever became worse in the evening and he began to have night sweats. His strength failed so much that he was obliged to give up his work in the latter part of June. He took a trip to San Francisco and returned to Nagasaki about September 10th, considerably better, as he thought, although he had not gained in weight. He did not notice the fever, but stated that the sweats were still present. On September 14th he noticed a slight circumscribed swelling on the right side of the chest in the midaxillary line on a level with the ninth rib. This increased rapidly in size and became very tense. He became alarmed, although he noticed no particular change in his general condition, and went to bed on the 18th. He was transferred to the *Relief* on September 22d. He stated that, since landing in the Philippines in April, 1899, he had not had even the slightest irregularity of the bowels. No previous history of dysentery. His appetite and digestion had been remarkably good.

On admission to my ward I obtained the foregoing history and found the following condition on examination:

Emaciation very marked; weight ninety-seven pounds; skin very pale and with a very slight yellowish tint; lungs normal; heart's action rapid and feeble, second sound slightly accentuated; pulse small and compressible, 96 a minute; temperature 100.4° F. On the right side of the chest, in the axillary line, there was a large tumefaction with fairly well defined borders. This extended from the eleventh rib below to the sixth rib above, was oval in outline, with a maximum width of four inches. Fluctuation was present, though it was rather doughy to the touch. Skin over tumor normal; very tender on pressure. The liver was markedly enlarged and tender, extending two inches below costal border. Bowels normal; appetite excellent; urine normal; a blood examination showed a leucocytosis of 13,000. Temperature on the evening of September 22d, 101.8° F. A provisional diagnosis of abscess of liver with perforation of diaphragm and chest wall was made, empyema being excluded by absence of physical signs and history.

I made an exploratory puncture on the morning of September 22d, finding pus containing dead amœbæ. In the afternoon of the same day I operated, making an incision three inches long over and parallel to the ninth rib, with its centre in the anterior axillary line. I found the subcutaneous cellular tissue necrotic and filled with pus, not a single large pus cavity, but numerous small ones in the interstices of the superficial fasciæ. On finding this condition I scraped out the whole cavity with a eurette down to the chest wall and found an opening between the eighth and ninth ribs in the anteroaxillary line. This opening was about five millimetres in diameter and pus was flowing from it. I found the ninth rib bare, its periosteum having disappeared over an extent of four inches. This destruction of the periosteum affected only that on the external surface of the rib, that on the internal surface being normal and attached to the rib. At the

extremities of the denuded portion, the periosteum presented a gelatinous condition, being thickened, very soft, and easily detached from the bone. The bone itself was not eroded. I extended the incision at each extremity along the rib to obtain sufficient room, and then removed the denuded bone (four inches). I enlarged the opening through the chest wall to three inches and evacuated 1,500 cubic centimetres of creamy pus mixed with a thinner reddish fluid. On exploring with the finger I found that the cavity extended downward and forward into the liver for several inches. Its walls were covered with shaggy, irregular, whitish, more or less broken-down, liver tissue. This was scraped away with a eurette. The cavity washed out thoroughly and drained with gauze and tubes. The wound was dressed daily; the cavity flushed out and repacked. The discharge was quite free for the first week, but afterward rapidly diminished. The temperature fell to normal immediately after operation, and remained so with the exception of a few days in the first week in October, when I attempted secondary suture of a part of the large incision.

The patient's condition rapidly improved, the night sweats ceased, and he began to gain weight. On October 11th (eighteen days after operation), he was allowed to get out of bed, and on November 7th he was discharged. At the date of discharge, forty-five days after operation, he weighed 127 pounds and was feeling better than he had felt for a year.

Remarks.

Ætiology of Amœbic Abscess.—In all the cases the *Amœba coli* were present in the contents of the abscess or in its walls. In cases I and III *Amœba coli* were present in the fæces; in cases II and IV they were not demonstrable. In case II they were present in the pus expectorated. In case IV they were present in the pus which had burrowed through the chest wall into the subcutaneous tissue. No other organisms were present in pus obtained from the abscess cavity, so far as could be ascertained by microscopical examination. The pus was apparently sterile, but this cannot be stated positively as no cultures were made from it.

Relation to Dysentery.—In two of the cases amœbic dysentery was present. In case III it determined the fatal issue, but in case I the dysentery was well in hand at the time of operation. In case III the dysentery began only one month before a diagnosis of abscess was made. This patient had never been in the tropics, but gave a history of having had dysentery in Idaho a year before. In cases II and IV no history of diarrhœa or dysentery, recent or remote, could be obtained, though both had lived in the tropics for over a year. No amœbæ were demonstrable in the stools of these patients.

Only one, Case IV, gave a history of a *malarial infection*, and it is doubtful in that case.

It is interesting to note that cases I and II were members of the same organization and, presumably, were subjected to the same environment.

Symptomatology and Diagnosis.—Fever was present in all the cases. It was very irregular as a rule. The highest recorded was in case II, in which on one occasion it reached 103.8° F. The average maximum in the four cases was about 102.5° F. Chills were not present in

any of the cases. Sweating occurred in cases II and IV. These sweats usually occurred after midnight. Pain in the shoulder occurred in all four cases. Pain in the right hypochondriac region was present in all. *Tenderness* over the lower intercostal spaces and at the costal border on right side was present in all the cases.

The bowels were perfectly regular in case IV. In case II there was constipation. In the other two cases there was dysentery. *Emaciation* was one of the most prominent features in all cases. *Leucocytosis* was present to a slight degree in all cases. In cases II and III, where the local destruction was most intense, it was less than in the two cases where recovery ensued.

Appetite was excellent in all four cases. I think this of some value in diagnosis. Even in cases II and III the appetite was good until near the fatal termination. There was neither nausea nor vomiting, nor appreciable jaundice in any of the cases.

Cough of a dry, hacking character was present in cases I and II. In case II there were fits of severe coughing after rupture of the abscess into the lung.

Urine was normal in quality and quantity in all cases.

Heart.—In the two fatal cases there was a pericardial effusion of about six ounces. In all the cases the heart's action was rapid and weak and the pulse very compressible. The two patients who recovered bore anæsthesia very badly, and required powerful cardiac stimulants and saline infusion.

A *positive* diagnosis cannot be made except by the exploring needle. A large needle with an aspirator should be used, as the pus will usually not flow unless assisted by aspiration.

One instance has recently come under my observation in which plastic pleurisy, affecting the lower portion of the right pleura, has closely simulated abscess of the convexity of the right lobe of the liver. It is evident that empyema might still more closely resemble liver abscess, particularly a sacculated empyema near the base.

Number of Abscesses.—In cases III and IV the abscesses were single. In case II there were three abscesses. In case I there were probably two.

Site.—In cases I, III and IV the abscess was situated in the convexity of the right lobe. In case II one was on the convexity of the right lobe, one on the under surface and the anterior border of the right lobe, and one in left lobe.

Treatment.—Is entirely operative, and of course the operation should be performed so soon as diagnosis is made, the method depending upon the site of the abscess and other circumstances.

NAGASAKI, JAPAN.

AUTO-INTOXICATION
FROM RENAL INSUFFICIENCY,
WITH AND WITHOUT DISEASED KIDNEYS;
WITH REPORTS OF
SOME REMARKABLE CASES.

BY JAMES T. JELKS, M. D.,

HOT SPRINGS, ARKANSAS,

PROFESSOR OF GYNÆCOLOGY AND SYPHILOLOGY IN BARNES MEDICAL COLLEGE, ST. LOUIS, MISSOURI; PROFESSOR OF GENITO-URINARY SURGERY AND VENEREAL DISEASES IN THE COLLEGE OF PHYSICIANS AND SURGEONS OF CHICAGO; SURGEON TO THE OZARK SANATORIUM, ETC.

MY attention was specially called to this subject several years ago by reading Bouchard on Auto-intoxication, Haig on Uric Acid, and, later, papers from the lamented Etheridge, of Chicago, and L. Duncan Bulkley, of New York. Bulkley wrote of Urinary Insufficiency in its Relation to Diseases of the Skin. Since then, I have read what Purdy has to say on the subject, and for years have made a point of examination of the urinary output (for twenty-four hours) of every patient who consults me. I wish to assure you that it has been a revelation to me, and the therapeutics based on this revelation has enabled me to accomplish some marvellous results.

We have been accustomed to think of uræmia as a result of diseased kidneys; I now know that it may occur in a person whose kidneys are perfectly sound. We have been taught recently by Bondurant and others that Bright's disease is a frequent factor in the causation of insanity. I know that insanity may supervene in a patient who, so far as can be learned, has no family defect in this line, who has no organic disease of the kidneys and is simply suffering from uræmic mania, or, if you please, insanity.

According to Purdy, Etheridge, Haines, and Haig, the amount of urinary solids eliminated daily should bear a certain proportion to the body weight. After forty years of age this amount is not so great, and hence a deduction is made from the standard. From forty to fifty years, ten per cent. is taken from the amount the person should pass; from fifty to sixty years, twenty per cent., and from sixty to seventy years, thirty per cent. A man, say twenty to forty years of age and weighing 160 pounds, should pass 1,168 grains of urinary solids daily; if he passes by actual measurements only 500 grains, what has become of the 668 grains? Suppose this to continue for days, what will be the condition of the patient? One of several things may occur; either a general condition of uricacidæmia, manifesting itself in vertigo, contracted capillaries, arteriosclerosis, cold skin, especially of the extremities, so-called sick headache, which is now recognized as uric-acid headache; "the blues" or melancholia, palpitation of the heart, interrupted heart beat, various forms of skin diseases, rheumatism, gout, endocarditis, pericarditis, myocarditis, hysteria, epilepsy, and genuine insanity. Can it be possible that all these things may be

Doctor Stricken Blind.—Dr. Chestnut, medical superintendent of the Winnipeg, N. Y., General Hospital, was recently suddenly stricken with blindness while attending to his duties.

the result of faulty elimination by the kidneys without the presence of disease in these organs?

In the report of the following cases, I have divided them into two groups; those with interstitial nephritis, and those without any organic lesion of the kidneys. I would especially call your attention to the relation of auto-intoxication to disease in women. In recent years, gynæcologist is another name for surgeon, and rightly so. But I wish to say that many women who come to us do not need "local treatment," and do not need surgical intervention; or, if they seem to need the latter, it is only apparently so. They are not cured by surgical procedures. Many would be cured if we took a broader view and gave these patients a general overhauling and a general line of treatment calculated to put all their emunctories into good working condition.

Our fathers were very nearly right when they purged all patients and gave so many of them calomel and squills. Here were remedies which stimulated elimination by the bowels and kidneys, and the result was a general feeling of well-being. This position is well illustrated by the popularity of patent medicines. Practically, all of them purge and stimulate the kidneys and eliminate waste products; thus the vital processes are relieved of the accumulation of toxins which are naturally produced by tissue metabolism. Practically all diseases of adult life, not infectious in character, are results of faulty metabolism and faulty elimination. If we can correct these defects our patients will be cured. Before reporting the cases I will call attention to the part that potassium salts play in the rôle of urinary intoxication, and from this you will readily see, that no patient suffering from defective urinary elimination should have any salt of potassium under any circumstances. I would especially warn against the error of giving bromide of potassium for the nervousness of these patients, or acetate or citrate of potassium as urinary stimulants.

Bouchard, on page 123 of his work on Auto-intoxication, says "Where the emunction of urine falls to one half or two thirds of what it ought to be," that "there is produced in the organism an accumulation of mineral substances, particularly potassium." Again, on the same page, "We know that among uræmic phenomena there may be, in certain conditions, a preponderance of the action of potash which may represent two thirds of the toxicity instead of one third." Quoting again from Bouchard, on page 125 we find: "If one kilogramme of man eliminates in twenty-four hours a quantity of urine capable of killing 461 grammes of animal, the proportional part that potash plays, is 217 grammes out of 461—almost one half." Hence we say, under no circumstances give any salt of potassium to any patient whose kidneys are inflamed or inactive. In one of the cases referred to hereafter, I produced uræmia by giving bromide of potassium to quiet a distressing nervousness; again, to the patient I gave acetate of potassium, together with an infusion of digitalis, to assist the latter in increasing the

urinary output. The result was an attack of uræmia which subsided when the potassium salt was eliminated. In the treatment of these cases the remedies used are as follows: Squill, calomel, milk, and large rectal or hypodermic injection of deci-normal saline solution; digitalis or its derivatives, sodium phosphate, sodium salicylate, and vichy water. The small quantity of potassium present in the vichy is not deleterious.

All of these remedies were used in connection with the baths, where it was possible to give them, and these patients were ordered to drink from one half to one gallon of water from the hot springs daily. Several of them were inmates of the Ozark Sanatorium. The diet consisted of fruits, vegetables, milk, and not more than three or four ounces of meat in twenty-four hours.

An easy method of ascertaining the amount of urinary solids is to collect the entire amount of urine for twenty-four hours. Let me ask you to insist on this with your patients, or they will bring you one half or one third of the amount. Take the specific gravity and multiply the number of ounces by the last two figures of the specific gravity, and to this amount add ten per cent. This will give you a very close approximation to the amount passed by the patient; or, you may multiply the last two figures of the S. G. by the coefficient of Häser, 2.33; this will give you the number of grammes in 1,000 cubic centimetres of urine; then, if the patient has passed 1,500 cubic centimetres, you have a simple sum in arithmetic as follows: Say the urine is 1,020 S. G. and the patient has passed 1,500 centimetres, you proceed thus:

$$20 \text{ by } 2.33 \text{ equals } 46.60 \text{ grammes in } 1,000 \text{ cubic centimetres, therefore } \frac{46.60 \text{ by } 1500}{1000} \text{ equals } 69.9 \text{ grammes of solids.}$$

Personally I prefer the method advocated by Etheridge, Bulkley and Haines, viz., multiply the number of ounces for the twenty-four hours by the last two figures of the S. G. and add to the result ten per cent.

For patients between forty and fifty years of age, deduct ten per cent.: for those between fifty and sixty years.

twenty per cent.; and for those between sixty and seventy years, thirty per cent.

CASE I.—W. J., aged forty years, weight 170 pounds. Came to Hot Springs for disease of the rectum, which was pronounced syphilitic and for which his physician gave him mercury and iodide of potassium, the latter in increasing doses until 240 grains daily were given. The last ten days of the treatment the patient grew rapidly worse, became delirious and weak, was put to bed and a watch was set over him. Delirium increased until his family decided to send him to some institution for nervous diseases. At this point I was called in consultation with two other physicians. The physician in attendance thought the patient was suffering from syphilis of the brain. This I questioned for several reasons, of which one was that the symptoms all came on after the large doses of iodide of potassium were reached; and, knowing that potassium salts enter largely into the ætiology of uræmia, I thought that the man was suffering from urinary intoxication. His urine for twenty-four hours showed twenty ounces, 1,010 S. G., albumin and hyaline casts. This gives 240 grains of urinary solids, as against 1,237 that he should pass. The mercury and iodide were discontinued, and, at the request of his physician, who was on the point of leaving for his vacation, I took charge of the case. He was given one quart of vichy water daily, one glass of sweet milk every two hours, and a tablespoonful of infusion of digitalis after meals. His brain cleared up in ten days.

CASE II.—Mrs. B., aged fifty years, weight 90 pounds. Great depression; always has the "blues," and feels that she is dying; is constantly saying so to her family and friends, and accuses them of want of affection, though they are devoted to her. Analysis showed albumin and casts. She should have passed 500 grains daily; actually passed 170; stored 330.

CASE III.—Mrs. M., of Kentucky, aged sixty-five years, weight 170 pounds. Rheumatic pains. Examination showed albumin and casts. She should have passed 1,060 grains daily; actually passed 264; stored 796.

CASE IV.—Mrs. J. Heart very irregular, rapid and intermittent, delirium and constant talking, singing or counting with incessant motion of the hands or feet; an utter impossibility to keep her quiet, though there was no violence. Urine for months showed no albumin and no casts. After a prolonged course of diuretic, which is a salicylate of theobromine, casts and albumin appeared in the urine, the latter in about fifty per cent. by volume. She has had in the last twelve months four attacks of dropsy. I placed her on infusion of digitalis and vichy water with nitroglycerin, and the urine increased to 100 and occasionally to 140 ounces daily. At this point all symptoms of uræmia disappeared and her heart lost much of its irregularity.

CASE V.—Dr. J. P., aged sixty-four years, weight 190 pounds. Rheumatism in knees, vertigo, and great weakness. Urine showed no albumin. Should have passed 910 grains daily; actually passed 364; stored 546. Treatment as above outlined for one month, in connection with the baths, relieved him of all his symptoms.

CASE VI.—Mrs. G., aged thirty-three years, weight 125 pounds. Intense nervousness, gets very melancholic and cries easily. No albumin and no casts. Should have passed 745 grains; actually passed 389; stored 356.

CASE VII.—J. A., aged thirty-five years, weight 150 pounds. Rheumatism in hands and feet; neither albu-

min nor casts in urine. Should have passed 1,150 grains of solids daily; actually passed 396; stored 754. In two weeks, under digitalin, he passed 704 grains and was steadily improving.

CASE VIII.—Colonel B., aged sixty-one years, weight 135 pounds. Rheumatism in feet, back and knees. No albumin, no casts. He should have passed 821 grains of urinary solids daily; actually passed 572 stored 249 grains.

CASE IX.—Mr. J., aged forty years, weight 220 pounds. He came to me suffering from an attack of carbuncles, with high fever. After he was operated on, fever disappeared, wound healed. Later on he became delirious, and we were compelled to tie him to his bed. He was as "mad as a March hare." Urine was very scant in quantity and high specific gravity. At one time, we seriously considered sending him to an insane asylum. Under digitalin, vichy water, hot water, and milk, the urine increased in quantity, and when it reached 100 ounces his brain cleared up.

CASE X.—Mrs. L., aged thirty-eight years, weight 130 pounds. Very nervous and depressed. For the last seventeen years has had facial neuralgia about every twenty days. Urinalysis showed no albumin, no casts. Should have passed 780 grains daily; actually passed 229; stored 561.

CASE XI.—J. W., aged forty-nine years, weight 160 pounds. Lawyer, very nervous, vertigo, unable to work with vigor. No albumin, no casts. Should have passed 1,097 grains; actually passed 792; stored 305.

CASE XII.—Mr. D., aged thirty-eight years, weight 240 pounds. Rheumatic pains over body; no albumin, no casts. Should have passed 1,330 grains or more of solids; actually passed 720; stored 610.

CASE XIII.—Dr. R., aged forty-two years, weight 170 pounds. Rheumatism; no albumin; no casts. Should have passed 1,150 grains; passed 728; stored 422.

CASE XIV.—Mr. L., aged thirty-eight years, weight 170 pounds. Vertigo, melancholia, and very irritable. Hands and feet burn all the time; pain in calves of legs and lumbar region; no albumin, no casts. Should have passed 1,237 grains; actually passed 363; stored 874.

CASE XV.—Mr. O., aged thirty-five years, weight 175 pounds. Urinalysis showed no albumin, no casts. He suffered great depression, weakness, interrupted heart beat and intense melancholia. Passed twelve ounces of urine with a specific gravity of 1,030; should have passed 1,250 grains of solids; actually passed 396; stored 854.

CASE XVI.—J. L., aged fifty-eight years, weight 170 pounds. Urinalysis showed no albumin and no casts. Gout in great toe. Should have passed 991 grains of solids daily; actually passed 297; stored 694.

CASE XVII.—Dr. T., aged forty-eight years, weight 160 pounds. Vertigo, melancholia, difficulty in keeping up conversation; excluded himself from society; saw no one if he could help it; apprehended epilepsy. Urinalysis showed no albumin, no casts. Should have passed 1,040 grains daily; actually passed 374; stored 666.

CASE XVIII.—Mrs. M., aged forty years, weight 150 pounds. Vertigo, low spirits. Urinalysis showed no albumin, no casts. Should have passed 850 grains daily; actually passed 572; stored 278.

CASE XIX.—E. N., aged thirty-nine years, weight 165 pounds. Great vertigo; could not attend to business, could scarcely get about and frequently fell down. No albumin, no casts. Should have passed 1,120 grains; actually passed 432; stored 688.

CASE XX.—Mrs. J. S., aged fifty-seven years, weight 90 pounds. Recently suffered from an attack of herpes zoster with great pain in the intercostal nerves. Should have passed 500 grains daily; actually passed 308; stored 192.

CASE XXI.—J. G., aged thirty-seven years, weight 170 pounds. Rheumatism in hands, feet, and knees. Uranalysis showed no albumin and no casts. Should have passed 1,237 grains daily; actually passed 531; stored 706 grains.

CASE XXII.—J. S., aged forty years, weight 250 pounds. Consulted me on September 15th. For the last week he had been troubled with great vertigo, weakness, and heaviness of legs. Could not stand. Uranalysis showed nineteen ounces and a half, with a specific gravity of 1,025. Should have passed 1,400 grains daily; actually passed 487; stored 913.

CASE XXIII.—Colonel J., a very prominent politician, suffered from an uncontrollable desire to talk. He had a perfect diarrhoea of words, and impressed people unfavorably; they thought he was going crazy, and so reported him. When he consulted me this was the only noticeable feature about the case. Uranalysis showed there was no albumin and no casts, but he was eliminating 1,750 grains of urinary solids daily when he should have passed only 1,260. Here was a plus elimination of 490 grains a day. This was strange, and it occurred to me that the plus elimination of these poisons set his tongue wagging continuously; in other words, he was suffering from a too rapid elimination of toxins which had previously been stored in large quantities. He was relieved by giving him for one week, nitrohydrochloric acid, and then sodium salicylate in addition to the acid. Recovery was complete and permanent.

In closing, I will say that those patients who are suffering from renal insufficiency because of nephritis usually die, not from the nephritis, but from the cardiac complications; namely, the hypertrophy and subsequent dilatation with which, sooner or later, all these cases are afflicted. Hence, the main indications for treatment are connected with the heart. If it is pounding because of capillary contraction or arteriosclerosis, nitroglycerin, opium, chloral hydrate, or iodide of sodium should be given to overcome the peripheral resistance. Careful watch should be kept on the heart, and if dilatation is threatened, digitalis infusion or digitalin should be prescribed, with rest in bed. In using digitalin I always order what is known as "German Merck" digitalin in preference to the American preparations or the "French Merck." This remedy I give in doses of from one fifteenth to one eighth of a grain three or four times a day.

218 CENTRAL AVENUE.

INTESTINAL OBSTRUCTION.

By LOUIS A. HERING, M. D.,

COLORADO SPRINGS, COLORADO.

"MECHANICAL interference with the passage of fæces through the bowel" defines this affection in a sense at once comprehensive and explanatory. When we come to consider its pathogenesis, and realize that it is the result of

several distinct, independent disorders and is a condition rather than a disease *per se*, the classification into acute or chronic is acceptable, and the sub-classification into partial or complete appeals to our understanding as proper.

This paper will treat of that class of cases essentially acute in their manner of onset, and complete in type and character.

Among the structural changes bearing a causal relationship to the condition under consideration are mentioned intussusception, internal strangulation or constriction, volvulus, stricture or compression, and congenital malformation; causes other than structural, are functional obstruction and impaction of fæces or of foreign bodies. Since the cases coming under the consideration of the writer have been in the adult, the causes accepted as operating in children may be barred from consideration. I may state, however, in passing, that I have been impressed by the frequency of intussusception as a cause of obstruction in the adult. This condition is readily conceded by most pædiatrists to be a very frequent cause in children, but is somewhat hesitatingly admitted to consideration as a factor in the adult by most writers on the subject. I can confidently state that it must not be entirely eliminated as a cause operating in the adult and that it is a more frequent type of obstruction than has been heretofore believed. Again, it is a question with me whether invagination is a primary or an associated cause when fæcal impaction can be diagnosed as present, giving us the proposition to consider whether, primarily, we may not have an invagination at the ileocæcal valve (which D'Arcy Power (1) asserts to be the seat of obstruction in from forty to sixty per cent. of cases), the pathological changes incident thereto laying low the peristaltic wave of the intestinal tract beyond, and thus allowing the lodgment or impaction of fæces; or whether the fæcal accumulation may be considered as primarily active, and the back-flow of gases arising from the accumulated waste matter as producing the intussusception at the ileocæcal valve, the distention acting as a stimulus to peristalsis, thus driving the ileum into the cæcum, and, in the event of this variety of obstruction being complete, driving the whole into the colon, the ileocæcal valve forming the apex of the intussusception.

One authority states it as his opinion that the active cause of invagination is irregular peristalsis; probably, a quiescent state of a portion of the intestine with hyperperistalsis of an adjacent portion would be a better explanation, the active portion being driven into the distended and inactive portion. Colic, diarrhoea, and constipation are each in turn advanced as causative factors favoring the development of this condition. In the cases under consideration obstinate chronic constipation was the cause.

Internal strangulation, or constriction, is tabulated as causing about thirty-five per cent. of all cases, the ileum being the portion of the intestinal tract most frequently

involved. Fibrous bands and adhesions resulting from peritonitis are cited as common causes; the vermiform appendix, by attaching itself to some point in the pelvis, may become a constricting band and in this way produce obstruction (2).

Volvulus contributes from about three to ten per cent. to the fatal cases. The common situation is the sigmoid flexure. The cæcum is also a frequent seat of the accident; the lesion in this case generally consists of a twist in the long axis of the gut, or a loop of the bowel may be twisted around another, or, again, the gut may be bent sharply upon itself.

Stricture and compression rarely produce complete obstruction, and they result generally in chronic constipation. Cicatricial contraction following ulceration, as occurs in dysentery, syphilis, tuberculosis, and cancer, is the most common cause of stricture. In my experience, chronic constipation, obstinate in type and character, has occupied oftenest the causal relation to acute intestinal obstruction.

"I go along all right for a time, then become constipated—after four or five days I pass a lump as hard as a stone, it seems, and then I have relief for a time," was the narrative of his complaint by one patient who subsequently was down with obstruction with perforation of the bowel. It will be found that a goodly percentage of cases of this malady are primarily due to fæcal impaction high up in that portion of the descending colon known by the name of *S romanum*, which sets up secondarily, by a reversal of peristalsis, an invagination of the ileum into the cæcum at the site of the ileocæcal valve. In cases coming under my observation the cause and effect mentioned seemed to be operating as evidenced by physical signs and clinical symptoms.

Syndromology.—The tripod of symptoms announcing acute intestinal obstruction is generally stated to consist of pain, vomiting, and entire absence of stool. These are the rule to which the exceptions are many; thus, one of the writer's patients passed a very small quantity of fæcal matter some hours before making his exit. Such an occurrence, happening in the practice of the diffident, dilatory practitioner may prove the soothing syrup which lulls him into inactivity, if I may be allowed the vulgarity to impress the truth. In this same case, also, the patient had ceased vomiting; and if cessation of vomiting is regarded as a herald of signal success attending upon waiting tactics, it may prove illusory. In another case, while the rectum was being examined by a colleague who had been called in consultation, gas was passed, and I believe that he was led to make a more favorable prognosis from this fact; vomiting had also ceased in this case.

Pain is a constant symptom and is of an aggravated, agonizing character, closely simulating that of gastralgia and setting in suddenly, as a rule. It may be all over the abdominal area, but careful inquiry will elicit the fact that it seemed to start on the right side over the site of the cæcum, which, upon pressure, will often be found to

be the tenderest point. Of the gastro-intestinal symptoms, the earliest in evidence is the belching of gas, becoming more and more frequent as the case progresses; eventually, after three or four hours, or, frequently, later, vomiting sets in, first of food and other matter, followed by mucous material, and, finally, if perforation has not taken place in the interim, fæcal matter is ejected. In one of my cases there was persistent vomiting of bile and no fæcal matter, which of course ceased after perforation had occurred. The vomiting was projectile, almost incessant, and most distressing. Hiccough was present at some time in all my cases.

The entire absence of stool is essential to establish a diagnosis of complete intestinal obstruction, bearing in mind that small bits of fæcal matter may be detached from the mass and be passed during the efforts at defæcation; no flatus escapes *per rectum*, or very little, and this only at long intervals. The temperature is very little elevated, and, in the cases under consideration, showed frequent remissions to normal at the morning observation; at no time was the rise more than 1° F., notwithstanding the slight thermometric range. Thirst was so pronounced as to attract attention, thirst which could not be appeased; the temperature chart is, therefore, of little value as a guide in this affection, unless there is a subnormal temperature due to gangrene, perforation, or septic peritonitis, all of which cause rapid collapse. The pulse increases steadily in rapidity and is small and wiry.

Gaseous distention of the abdomen was prompt and progressive, so that the site of the umbilicus formed a deep pit, and I could observe in all my cases peristaltic movement, which soon disappeared. Pitting could be freely demonstrated on the left side of the abdomen over the site of the impacted fæces, and extreme tenderness over the whole abdominal area, most pronounced over the cæcum, less in evidence over the impaction; only elicited there on deep pressure. Rectal examination demonstrated a small tumor-like feeling on the left side of the pelvis. Upon percussion, the abdomen proved to be superresonant, tympanitic in all its regions, the tympanites being exaggerated over the site of the cæcum, modified over the location of the impacted fæces upon light percussion, and flat upon deep percussion. Tenesmus was always present, together with blood passed *per rectum*.

There was noticed a rapid loss of flesh and strength, and the ocular padding of adipose tissue had perceptibly vanished by the third day of illness. Borborygmi, so loud as to be heard at some distance from the bedside, were frequent. Toward the close, there was noticed great restlessness; the face was pale and cold, and the body clammy to the touch; the eyes were sunken, the nose was sharp, and the features were pinched; the voice was inaudible or whispering; the pulse very rapid and small, and the temperature was slightly elevated, or, when shock was established, subnormal; the tongue was dry and glazed, thirst was increased, the mind in exceptional cases remained clear, and the patient at times tossed

about moaning, but oftener complete euthanasia was present.

Prophylaxis.—Much may be accomplished by prophylactic measures, *e. g.*, an abdominal binder should be recommended for those presenting the condition of enteroptosis, or in those habitually constipated (and I believe that this habit predisposes the largest quota to intestinal obstruction); a fixed habit should be formed of going regularly to stool each day at a certain hour. As to diet, the foodstuffs especially to be advised are fresh green vegetables and succulent fruits. The eating of an apple at bedtime, in itself seemingly an insignificant matter, is an efficient aid to movement of the bowels the next morning; however, to secure this effect, eating an apple should become a fixed habit. With these measures should be conjoined systematic massage of the abdomen. A very excellent practice is to flex the body several times night and morning while in a standing position, as recommended by Tyson (3); and, lastly, since I have been able to trace this condition in my cases to some faulty action of the liver, I have become partial to the use of phosphate of sodium administered in a glass of hot water before meals.

Treatment.—In acute intestinal obstruction, gangrene sets in early; indeed, Eskeline would have it beginning as early as the third day. It is evident, therefore, that one must bring into play a faultless perception and quick decision in meeting the exigencies which arise in this condition; exhaustion steadily advances by forced marches and soon wrests from the patient any vitality that would stand him in good stead should an operation be determined upon. I have recently operated upon a patient in whom ileus followed vaginal hysterectomy for cancer. I opened the abdomen early on the second day after signs of obstruction had become evident, and found that the bowel had been perforated in a minute area of necrosis, and that the pelvis was full of liquid fæcal matter; this emphasizes the importance of operating early before the gut is weakened by inflammation and its attendant sequelæ.

Among medical measures which may be instituted as precursory to surgical intervention in the event of failure, high rectal enemata head the list. These should always be given with the patient in the knee-chest position, but, if the patient is too weak to assume this posture, a left or right lateral semiprone position will answer. The enemata should be carried by means of a long, flexible rectal tube as high up as one can succeed in introducing it; plain warm water, or water and glycerin, or water to which a modicum of turpentine has been added, the turpentine being emulsified by shaking up with an egg, may be used. If three or four enemata do not yield results, it is, in my judgment, unwise to delay cœliotomy. It is risky to administer purgatives, although I have on occasion given a single large dose to see whether it would pass through.

Opiates should be withheld as part of the medical

treatment. Murphy (4) warns against giving opiates, since they mask the symptoms; they should only be given during the time consumed in preparing for operation, to obtund the pain. In the event of failure with the enemata, all observers are agreed that early operation offers the only salvation for the patient. Murphy (5) operates early; McArdle (6) advocates early operation; Broca (7) operates after twenty-four hours; Naunyn (8) also urges early operation, and holds that the best results are obtained in the first three days.

Operative Treatment.—Abdominal section in the treatment of intestinal obstruction is one of the most formidable operations in surgery, and the surgeon who undertakes it should be familiar with the anatomy of the abdominal cavity and its contents. A good surgeon must necessarily be a good antiseptist and aseptician; therefore it is unnecessary for me to lay down here a description of the technique for his guidance. Suffice it to state that strict precaution should be exercised to have everything concerned in the operation sterile, remembering that as soon as the abdomen is opened sterile normal salt solution should replace the antiseptic solutions. Sponges, gauze pads, etc., for use in the abdominal cavity, should all have been sterilized by heat, and should not come in contact with the chemical antiseptic solutions. If morphine has not been already given to the patient, I deem it excellent practice to administer it just before beginning the operation, and it is well, also, to give strychnine hypodermically. I have never been able to introduce a stomach-tube with uniform success in this condition, on account of the eructation of gas and the vomiting; but it is recommended to precede the administration of the anæsthetic, and also as a medical measure to relieve the nausea and vomiting.

The obstruction can rarely be located to a certainty beforehand; it is best, therefore, to make the incision through the right rectus muscle, large enough to at least admit the hand. Much trouble will be experienced in handling the intestines, on account of the contained gas; it is best to give vent to this, not, however, until the obstruction has been found. The opening for this purpose should be transverse to the long axis of the gut, and should be closed with Lembert sutures.

In the systematic examination of the intestines for the purpose of locating the obstruction, it is well to mark the point of beginning by making a slit in the mesentery, running a piece of gauze through the opening, and loosely tying it, not forgetting to repair this same slit when finishing the operation. If the patient is in good condition, he may be put in the Trendelenburg position, since it facilitates the handling of the gut. If the opposite condition prevails, then the dorsal decubitus should be assumed, and the intestines protected by warm gauze compresses, moistened with the normal salt solution.

When the obstruction is located and the involved portion of the gut is resected, if necessary, the next step which gives one the most perplexity is the method of

establishing anastomosis. I have used the old method of suturing advocated by Abbe (9), and I give his technique. After the resection of the gut has been done, and the two free ends have been closed in the usual manner, the two ends are laid alongside of one another, and two rows of continuous Lembert sutures, a quarter of an inch apart, and one inch longer than the proposed cut, are applied. Each thread should be twenty-four inches long and should be left at the end of its row, still containing its needle; the bowel is now opened a quarter of an inch from the sutures for four inches, both rows of sutures being to one side of the cut; the opposite portion of the bowel is next opened in the same manner; the two adjacent cut edges are now united by an overhand suture, the needle piercing both the serous and mucous coats, and in this way stopping the bleeding vessels, which have previously been secured by hæmostatic clamps; the cut free edges are similarly whipped, after which the serous surfaces on the opposite side of the opening are approximated and secured by two rows of continuous Lembert sutures, the first two threads being utilized for this.

I have here detailed the simplest method which I know of, and it is free from the many risks which attend the employment of artificial aids to anastomosis, of which there are many, *e. g.*, Senn's bone plate, Abbe's catgut rings, Robinson's untanned leather plates, Stanis's cartilage plates, Baracz's turnip plates, Dawbarn's potato plates, Murphy's button, and the various forceps and appliances which are introduced from time to time to facilitate suturing. I think that, after a trial of all of these, the surgeon who is called upon to do much work with the intestines will applaud the simpler method given above. I have lately used on dogs a contrivance which I fashioned myself somewhat after the LaPlace forceps, and I must admit that I like it; it is, however, constantly in the way, and is a clumsy method.

In resecting the gut, it is well to clamp above and below the portion to be so removed, surrounding the portion to be cut away with sterile gauze to protect the peritonæum. If an end-to-end anastomosis is decided upon, I have found a sterilized potato, cut into the shape of a double-pointed cone, serviceable; it can be made to fit all sizes of gut and inserted into the ends of the intestine, and these then drawn over the potato and approximated. It furnishes a *point d'appui* for passing the suture. The sutures should not be passed through the entire bowel, as practised in Maunsell's (10) method, on account of the element of risk of producing infection, a method, it seems to me, just as pernicious as the advice given to evacuate the gas in the bowel by needle punctures.

After the bowel has been repositied, the abdominal incision should be approximated according to the technique laid down by Kelly (11), of Baltimore. This avoids disturbing the patient for the removal of sutures, and is more efficient than the older methods.

After-treatment.—It will always be wise to surround the patient with heat when putting him back to bed after

an operation. I have sustained my patients by rectal alimentation, and have not allowed any food to enter the stomach for two days. This is an unnecessarily long period, and I now begin the administration of peptonized milk in small quantities after a lapse of twenty-four hours in favorable cases; and, later, if this is well borne, of egg albumen water. This regimen is continued up to the fourth or fifth day, and, if the pulse is normal and the general condition is encouraging, I advise a semi-liquid dietary, gradually coming back to the ordinary diet as time goes on. In the beginning, when nothing is allowed by the stomach, thirst is bitterly complained of; this may be somewhat appeased by sponge baths or rectal enemata of warm normal saline solutions. Bismuth is advised by some, to allay the thirst. I have always found it too irritating and constipating in this condition, the action of the drug being probably enhanced by the paralytic condition of the intestinal tract.

In this condition, we have still the critical point to pass in securing action of the bowels. When this occurs, it is one of the most favorable signs, signaling, as it does, the successful removal of the obstruction and the restoration of peristalsis in the intestinal tract. Measures to move the bowel should not be instituted until the third day, and at this time the best preparation to give is effervescent citrate of magnesium, freshly prepared. Opiates should be withheld, because they impair peristalsis and, in that way, delay the spontaneous movement of the bowel.

SOME REMARKS ON EPIDURAL HÆMORRHAGE WITHOUT FRACTURE OF THE SKULL, AND REPORT OF A CASE.*

BY J. SHELTON HORSLEY, M. D.,

EL PASO, TEXAS.

THOUGH in recent years surgery has been advancing with seven-league strides, there is probably no region in which progress has been so marked as in the treatment of injuries to the brain and its membranes. Surgery of brain tumors and abscesses is in occasional cases brilliant, but on the whole unsatisfactory and productive of

*Presented before the Southern Surgical and Gynæcological Association, at Atlanta, Ga., November, 1900.

little good. In spite of the scholarly work of Victor Horsley, Munk, Ferrier, and others, location of brain tumors in the hands of skilled neurologists is most uncertain, and, even when they are located, surgical intervention is usually unjustifiable.

It is in traumatism of the brain and its membranes that the advances in physiology, backed by modern surgical methods, have proved of such inestimable benefit. Experimentally, it has been determined that the introduction of a non-irritating substance into the cranial cavity can be continued without producing cerebral symptoms until six and a half per cent. of this space is filled. Above this amount, evidences of pressure or compression are shown. If the amount introduced epidurally equals in volume one twelfth of the cranial cavity, fatal coma results. The effect also varies according to whether the substance is injected suddenly or gradually, the brain tolerating more compression under the latter condition. Pressure thus produced soon results in compression of the whole brain, and consequent cerebral anæmia.

The chief sources of epidural hæmorrhage are three: From the sinuses of the dura mater, from the veins of the diploe, and from the middle meningeal artery or its branches. This last is much the most dangerous, as the slight pressure which is produced will usually check hæmorrhage from the first two sources before much blood is lost, if no fracture exists.

The dangers of epidural hæmorrhage without fracture of the skull are, in the order of their importance, compression of the brain, shock, and exsanguination of the patient. The first is by far the most serious, and here localization of motor and sensory centres is of great value.

The diagnosis of this condition is most important, and in cases uncomplicated by cerebral injuries is comparatively easy, if a correct history of the case can be obtained. The symptom which is well nigh pathognomonic is an interval of consciousness between the time of injury and the first cerebral symptom. This interval may be a few minutes or many hours, depending upon the severity of the hæmorrhage. During this time the patient feels perfectly well. Of course, epidural hæmorrhage frequently exists when there is no such interval, but this class of cases will be found complicated with some trauma of the brain. Subdural or pial hæmorrhage is rarely sufficient to cause compression, and cortical hæmorrhage cannot exist without a lesion of the brain itself.

Other signs and symptoms of importance exist. There is usually some sign of injury to the scalp, if only a slight contusion. Inequality of the pupils is frequently found, the pupil on the side of the hæmorrhage being dilated. This, however, is by no means always true. The period of coma from compression comes on gradually and is heralded by stupor, convulsions, and paralysis. Early convulsions point to the first seat of

pressure. As it takes a considerable amount of blood to cause sufficient pressure for cerebral symptoms, by the time this quantity has accumulated a number of centres are covered and pressed on, and as pressure increases we find hemiplegia or paraplegia coming on gradually, according to whether the hæmorrhage is on the side or the top of the brain. In the latter instance there is hæmorrhage from points on both sides of the middle line as a rule. This paralysis is at some time associated with convulsions of the rest of the body, due to cerebral compression. Epidural hæmorrhage at a distance from motor centres or tracts, as in the frontal region, cannot cause convulsions or paralysis (including paralysis of the iris muscle) until it has produced general compression. The speech centre is soon affected if the hæmorrhage is near it. The breathing is slow, deep, and stertorous in a majority of cases, and is always slow when much bleeding exists. The pulse is usually slow and full, and later, when the heart and its ganglia become tired, and the centre of the vagus paralyzed, is rapid and weak. It is frequently of unequal volume on each side. The temperature is subnormal. With severe general compressions control of the bladder and rectum is lost.

Uncomplicated cases of epidural hæmorrhage without fracture, and of sufficient severity to cause diagnostic symptoms, should be operated on as soon as possible; but, as Abbe has so truly said, while speaking of perforations in typhoid fever, one should never be in such haste as to handicap himself too greatly by poor lights, poor assistants, or unfavorable surroundings. It should also be borne in mind that epidural hæmorrhage is frequently so complicated by injuries to the brain as to contraindicate an operation, or at least to affect the time at which it should be done. Dr. Charles Phelps, of New York, says: "If other intracranial injuries have been sustained which are obviously or presumably of immediately fatal character, operation will probably hasten rather than retard the catastrophe. It is only when symptoms point clearly to hæmorrhage as the essential, if not the exclusive, lesion that operation for its relief will afford legitimate hope of success." The operation of trephining is a comparatively simple procedure, and in the hands of a surgeon of ordinary skill should be practically without mortality, just as exploratory cœliotomy is. In cases where there is reasonable doubt as to the severity of the cerebral lesions it is probably best to trephine, remove clots, and stop bleeding. This will relieve pressure and give Nature a chance to take care of the other injuries. The steps for this operation are detailed in surgical text-books, and do not come within the province of this paper, but I wish to lay stress upon three most important features in the after-treatment, viz.: free purgation, rest, and cold applications to the head.

In reporting the following case, I am aware that it is not very rare, nor is it unusual in any large city hospital with an emergency service; and I should, perhaps, apologize for reporting it. But it is a very typical case

of epidural hæmorrhage without fracture, and shows what can be done for such cases if operated on at the proper time. For these reasons I trust it may be of some interest.

Mr. R. R., aged twenty-one, works in a steam laundry; previous health good. On March 4, 1900, about 9 P. M., he was struck on the head with a wooden club. He was momentarily stunned, but soon recovered and felt perfectly well. About an hour and a half after the injury he became drowsy, and within a few hours fell into a stupor. Dr. H. H. Stark was called in. At this time he could be aroused from the stupor, but would soon relapse into the same condition. The following afternoon Dr. J. A. Rawlings was called in consultation. The condition of the patient was rapidly becoming worse, and at 7 o'clock on the evening of March 5th these gentlemen kindly referred the case to me for operation. There was a small contusion on the left parietal eminence. The patient was in profound coma. His pupils were slightly contracted, were equal, and would not respond to light; his breathing was slow and stertorous, but not very deep; the pulse was irregular and intermittent, and on the operating-table, before the clot was reached, would vary from 110 to 160; the temperature was 97° F. The right side of his body and face was paralyzed, and the left arm and leg were in constant jerking convulsions. He had lost control of the bladder and rectum. The operation was performed at St. Luke's Hospital, with the assistance of Dr. Stark and Dr. Rawlings, at 8 P. M., an hour after the patient arrived. No anæsthetic was used at first, but convulsions of the left side proving annoying, chloroform was finally given. I intended making an osteoplastic flap with the trephine and Gigli saw, but, as the patient's condition was becoming rapidly worse and haste was demanded to relieve pressure, I trephined over the left parietal eminence and came down upon a large clot of blood. There was no fracture of the skull, not even a fissure. The trephine opening was enlarged with rongeur forceps, and a quantity of blood, estimated from four to six fluid ounces, was removed by means of the finger, a uterine curette, and small gauze mops on artery forceps. The opening was a little above the middle of the clot, which measured an inch and a half deep at its centre and covered an area about four inches in diameter. Only slight bleeding occurred after the clots were broken up and removed; so the space was loosely filled with iodoform gauze and a rubber drainage tube inserted. A few silkworm gut sutures were introduced and left untied. Bleeding from the scalp was free, but easily controlled by a continuous overhand suture of catgut, carried along the margins of the scalp wound. His temperature was 98.5° F. an hour after the operation, and did not vary as much as half a degree during the entire convalescence. Next morning the patient was conscious and answered questions intelligibly. On March 7th, the dressing was changed, the gauze and tube were removed, and the sutures, previously introduced, were tied. The first week the patient was inclined to be noisy at night. Some superficial suppuration resulted, but otherwise he recovered uneventfully. He was discharged on April 9th.

A Health Officer for Atlanta.—A movement is on foot in Atlanta looking toward the appointment of a salaried health officer for the city. The matter has been discussed in the city council and referred to a special committee for consideration.

THE CLOSURE OF CUTANEOUS WOUNDS WITHOUT SUTURE.

By HOWARD LILIENTHAL, M. D.,

NEW YORK.

INFECTION along the track of a suture is an accident which occasionally occurs in spite of every precaution known to surgical science. It is particularly annoying when the operation was supposed to be a clean one, and much of the final success depends upon absolute primary healing. Take, for example, the removal of the vermiform appendix during an interval between acute attacks. Here we strive to leave the abdominal wall as nearly normal as possible, with no weakened portion at the site of the incision. Primary union is essential if this ideal result is to be attained. Suppuration among the deeper layers of the parietes usually leads to the formation of an insecure cicatrix with the probability of hernia in the future. Now, it is a matter of common observation that ligatures and buried sutures, no matter of what material they may be, rarely become infected, but that the suppuration of stitch-holes in the skin is comparatively frequent. The most plausible explanation of this is that the sutures become infected from the skin itself. This is hardly to be avoided in a certain proportion of cases, because of the well-known impossibility of sterilizing the deeper layers of the living human skin, and when infection occurs it is apt to spread to the deeper parts of the wound even in the presence of drainage.

Certain suture materials appear to invite trouble more commonly than others. Catgut and the other absorbable animal substances not only are pabulum for bacteria, but in the presence of infection they swell by imbibition, thus plugging the suture-openings and causing retention. Silk, silkworm gut, and the other non-absorbable substances do not swell and may even act to a limited degree as drains in the presence of infection. Still, they, as well as the catgut group, may carry pathogenic bacteria from the skin to the deeper portions of the wound. Silkworm gut and the other rigid materials have the additional fault that they do not conform exactly to the position of the tissue planes, as does the more pliable silk. Spaces are therefore formed in the suture tract which, filling with lymph or blood clot, become septic in the presence of very minute quantities of infectious germs which the living tissue under other conditions would be able to counteract.

The subcuticular suture has been devised to meet the objections to the employment of stitches which perforate the skin. It is applied by passing the needle through the deep layers of the skin while the lips of the wound are everted, thus burying the stitches. This method is a decided improvement upon the older ones, but it is not always simple to carry out and requires more time than the other sutures. Besides, its removal in case of necessity may be a little complicated.

About four years ago I began testing various methods

of wound treatment, in selected cases, without the use of cutaneous sutures of any kind. The deeper layers of the wound were closed in the usual manner with the aid of suture materials of various kinds, absorbable and non-absorbable, but the wound in the skin was merely covered with sterilized gutta-percha tissue and left thus until the healing process was well under way, when the edges were approximated with strips of india-rubber zinc plaster, 20 per cent., made by Dieterich, of Helfenberg, Germany. This plaster is an elegant preparation, very adhesive and pliable and non-irritating. It was torn into strips about six inches long and from an eighth to a quarter of an inch wide, which were applied at an angle with the line of the incision. Bulging surfaces lend themselves most readily to this form of treatment, and here the strips may be applied at right angles to the wound. In depressions or hollows the strips must be placed at an oblique angle to the line of the wound. The front and sides of the abdomen are especially adapted to this kind of wound closure, while in the groins it is not in every case applicable.

The results were gratifying, the deep sutures healing in beautifully, whether they were absorbable or not. It then occurred to me to employ the method at the time of the operation instead of waiting until repair had begun. In other words, I would make use of an aseptic method of pre-antiseptic days, for the closure of wounds with plasters is very ancient. For nearly three years, in my hospital service and in private practice, I have as a routine treated wounds in this manner, and I am so well satisfied with the results of the procedure that I feel it my duty to recommend its general application. The wounds made in the operations for abdominal section, nephropexy, major amputation, kelotomy, and amputation of the breast are some of those which have been closed by the plaster, and thus far I have seen no infections attributable to its use in spite of the fact that Dieterich's plaster is not guaranteed to be aseptic and does not come in a sterilized container. For the last few months I have been using a plaster made in this country by Johnson & Johnson at my suggestion. They have found that the zinc-rubber plaster may be rendered perfectly sterile by exposing it to the fumes of formalin in a vacuum chamber, and the plaster is now furnished sterile and in a sterile container. The containers each hold enough plaster already cut in strips to close an ordinary wound six inches in length. It is sold under the trade name of Sterilized Z. O. strips. Any of the material which is left over is thrown away or it may be resterilized.

Before applying the plaster one must be careful to check all hæmorrhage and to dry the skin thoroughly with alcohol or ether. The strips are then laid on while an assistant adjusts the edges of the wound. The method should not be used when there is tension, but only when the wound can be closed without force. It is perfectly applicable to the partial closure of wounds

when drainage is employed. The strips should be removed on the fifth or sixth day by loosening both ends and drawing them toward the wound. If the adaptation of the edges has been careful, the wound in a clean case on removal of the plaster will look like a mere scratch. A second application of the plaster is not necessary, a dry sterile covering being sufficient. If at any part of the line the edges of the wound have not been accurately approximated, the surface should be thickly dusted with a dry aseptic powder.

In conclusion, I would say that a trial of this method of aseptic wound closure is earnestly advised. In addition to its advantages in the saving of time—often an important element when the patient bears the anæsthetic badly—it conduces to more perfect and aseptic healing, and does away with the necrosis of cutaneous tissue from constricting sutures.

TRACHEAL INJECTIONS IN THE TREATMENT OF PULMONARY TUBERCULOSIS.*

By T. MORRIS MURRAY, M. D.,

WASHINGTON, D. C.

I HAVE brought the subject of intratracheal injections before you in a preliminary report of the work now being done in my clinic at the Central Dispensary and Emergency Hospital. A. T. Modestoff, of St. Petersburg, was, I think, the first to put the intratracheal method of introducing remedies into the human organism upon a scientific basis. He maintained, as the result of many experiments upon dogs, that remedies so introduced penetrated to the farthest limits of the respiratory space. In 1888, we hear from Garrel, Boteq, and others advocating the intratracheal administration of creosote in cases of pulmonary tuberculosis. In 1889 Downie, of Glasgow, read a most interesting paper before the Medical and Chirurgical Society upon this subject. The injection used by him was twelve per cent. of menthol and two per cent. of creosote dissolved in olive oil. Of this as much as two drachms was injected at a sitting daily. He says that "out of forty cases so treated, all expressed feelings of benefit in several ways."

In describing the results of his treatment he observes that the patients breathe more freely, and where tightness or a feeling of constriction about the chest is complained of, this is rapidly relieved by the menthol injection. There is less inclination to cough.

"The patients at the infirmary say that they cough none at all for from four to eight hours after the injection, and if it be given at bedtime many whose sleep was previously much interfered with by the frequent recurring of cough rest the whole night long without once coughing. The expectoration becomes greatly reduced in quantity

*Read before the American Laryngological Association at its Twenty-second Annual Congress.

and much less offensive. In several of the cases the purulent element entirely disappeared, and what little expectoration continued to be discharged resembled the frothy expectoration of simple bronchitis. There was marked increase in weight in most of the patients thus treated." I have quoted Dr. Downie at length because his is the best exposition of the subject that I have seen and accords so nearly with my own experience.

The most recent contribution to the subject comes from Dr. Mundell, of Roubaix, who has substituted the essential oils for the usual creosote and menthol. The solution selected by him, after experiment, is the following:

Essence of thyme..... 5 grammes;
Essence of eucalyptus..... 5 "
Essence of cinnamon..... 5 "
Sterilized olive oil.....100 c. ctm.

Of this he injects three cubic centimetres three or four times consecutively. The results reported by him, which were most satisfactory, have been to some extent confirmed by my own cases.

The method of administering intratracheal injection is simple; the curved cannula of the syringe is passed between the vocal cords, and the fluid is slowly injected into the trachea. The syringe which I have employed is the Schadel syringe. The usual effect in a majority of cases is a slight explosive cough. I have not seen a single instance of glottic spasm follow even the first injection. Out of thirteen cases treated during the past seven months with the Mundell solution, all but three have been decidedly benefited, their cough and expectoration have been lessened, and their temperature has been lowered. These patients were not in the hospital, and could only be seen three or four times a week, and were very poor, with all which that means in the way of environment.

The advantage of the intratracheal injection over the usual methods of treatment in tuberculosis lies in the fact that the antiseptics used enter at once the field of their labors unaltered and penetrate to the farthest limit of the respiratory space, and, coming in immediate contact with the toxins as they are generated, bring about the beneficial results described without interfering with the digestive organs.

While I do not undertake to reach a conclusion as to the full value of this treatment in cases of tuberculosis, I think it can be fairly said that it does lessen the cough and expectoration, lower the temperature, and improve the general condition of the patient.

Therapeutical Notes.

Urotropin.—Dr. Edward L. Keyes, Jr. (*Therapist*, November 15th), in a paper read at the last Congress of American Physicians and Surgeons sums up the conclusions suggested by a consideration of five cases in which he had employed this drug, as follows: 1. Urotropin seems to be almost a specific in the treatment of some

cases of acute catarrhal pyelitis, uncomplicated. 2. To prove effective it may have to be administered in high doses until the urine is practically clear of bacteria, after which a smaller dose may suffice. 3. In judging of the effects of the drug, the centrifuge and microscope should be employed. 4. The dose must not be sufficient to cause pollakiuria and dysuria by irritation of the neck of the bladder. 5. The possibility of such an irritation cannot be overlooked, even when very small doses are employed. 6. Urotropin is extremely serviceable as a prophylactic of the various forms of urinary septicæmia and urethral chill. 7. Its routine employment both before and after operations on the urinary passages is indicated. 8. The urine containing urotropin occasionally has an escharotic effect upon wounds, which may constitute a contraindication to its employment.

For Præmenstrual Pain.—*Ἰατρικὴ Προοδος* for December, 1900, gives the following:

℞ Codeinc. $\frac{3}{4}$ of a grain;
Chloral, } of each. 15 grains;
Ammonium bromide, }
Camphorated water. 1 ounce.

M.

To be taken in one dose at bedtime.

A Tooth Wash for Chlorotic Patients.—Dr. Max Kahau recommends (*Berliner klinische Wochenschrift*, 1901, page 20) the following:

℞ Tincture of benzoin, } of each. . . . 1 ounce.
Tincture of rhatany, }

M.

Rinse the mouth thoroughly before and after meals, using one dessertspoonful of the mixed tincture in a glass of warm water, and swallowing a little.

Huchard's Hæmostatic Pills.—Six to ten of the pills made according to the following formula (*Berliner klinische Wochenschrift*, 1901, page 31) should be taken two or three times a day:

℞ Quinine sulphate. $1\frac{1}{2}$ drachms;
Extract of ergot. $\frac{1}{2}$ drachm;
Digitalis leaves, powdered, } of each. 6 grains.
Extract of hyoseyamus, }

M. Ft. pil. No. 40.

Herxheimer's Treatment for Scabies.—Captain W. D. Sutherland, I. M. S. (*Indian Medical Gazette*, November, 1900), records this note from Herxheimer's clinic: For scabies, Wilkinson's salve—

℞ Birch tar. $2\frac{1}{2}$ drachms;
Precipitated sulphur. 150 grains;
Green soap, } of each. 300 "
Vaseline, }

M. Ft. unguent.

All the affected region is smeared with this salve once a day for three days, and on the fourth day the patient is given a warm bath, even though he may be suffering from scabies eczema.

Or, the parts are painted with

℞ Balsam of Peru, }
Liquid storax, } Equal parts.

M. Ft. pigment.

This is applied once daily for three days and then removed with spirit.

By either of these methods the acarus is said to be killed, and the eczema is then treated.

NEW YORK, SATURDAY, FEBRUARY 9, 1901.

THE BELL BILL.

ASSEMBLY bill No. 167, entitled "An act to amend section one hundred and fifty-two of chapter six hundred and sixty-one of the laws of eighteen hundred and ninety-three, entitled 'An act in relation to the public health, constituting chapter twenty-five of the general laws,' " introduced into the New York legislature by Mr. Bell, was made the subject of a hearing last week. The occasion caused the gathering in Albany of a numerous concourse of opponents of the bill, consisting principally, if not entirely, of "Christian Scientists." Among them were rhetoricians of the kidney most revered by ill-balanced people, and there were some who seemed to have had the training of the stage manager, for at their command there was no lack of men and women to stand up and proclaim the wonders that had been wrought in their persons by the power of "Christian Science." The scene was as if a whirlwind of zealotry had swept away almost the last remnant of reason. And no doubt it had the desired effect upon the legislators.

The effect, it must be admitted, was facilitated by the unreasonable wording of the bill, a bill which, while intended to represent requirements unobjectionable to everybody but those who seek to evade responsibility for offending against the spirit of the old law, was really so sweeping as to chill most of those who would have given a more temperate measure their hearty support. If passed as originally drafted, the bill would violate the innate rights of man and carry us back to "blue law" days, if not to those of the Inquisition. We understand that it has been much modified, and we can readily recognize that essential modification was needed if it was to stand a ghost of a chance of passing. In the latest printed copy that has come under our observation we find the following passage: "Any person shall be

regarded as practising medicine within the meaning of this act who shall prescribe, direct, recommend, or advise for the use of any other person any remedy or agent whatsoever, whether with or without the use of any medicine, drug, instrument, or other appliance, for the treatment, relief, or cure of any wound, fracture, or bodily injury, infirmity, physical or mental, or other defect or disease." But emergency services and the administration of domestic remedies are not interdicted.

We believe, with Dr. Van Fleet, whose letter on the subject we publish in this issue, that the promoters of the bill never intended to visit upon the people of the State of New York such curtailment of personal liberty as would be its inevitable outcome if it were enacted in the form in which it was introduced. But good intentions cannot palliate the appearance of their palpable contradiction in a statute book. When the bill is so modified that it may be called temperate, we shall not be backward in advocating its passage. Meantime it seems to us best not to press its passage until it has been further amended so as to prove detrimental to nobody but those who are engaged in violating the spirit of the present law. We cannot support the bill in its present form, much as we deprecate illegal practice.

THE STATE PATHOLOGICAL INSTITUTE.

AMONG the notable acts of the Medical Society of the State of New York at the meeting held in Albany last week was the passage of a resolution praying the legislature not to reduce the appropriation for the Pathological Institute. The work of the institute has been severely criticised of late, and the criticism has probably inclined the legislature to look upon it somewhat with coldness; hence the need of such action as has been taken by the State society. The fault that has been found with the institute, it seems to us, has been petty, being largely founded on the contention that routine laboratory work, such as can conveniently be done in the State hospitals, has been to some extent sacrificed in order that deeper work, more far-reaching if comparatively barren of immediate results, might be prosecuted systematically and persistently. The institute has ably—to our mind, convincingly—defended itself, and we trust that the legislature will not follow the penny-wise-and-pound-foolish policy of crippling it.

The institute is young, and the problems it legitimately has to deal with are not such as can be solved offhand. Time and continued research, the devotion of

trained men for years, are absolutely necessary to the consummation of such work, if, indeed, it is ever to be consummated, for in medicine, and especially in such a difficult branch as psychiatry, new problems are forever cropping out, and no sooner has one of them been worked out than another presses forward. The research that finally culminates in the acquisition of precious knowledge is not the mere application of known methods of inquiry to one after another of a series of commonplace situations; methods, new ones, must be devised, and to arrive at them the investigator, no matter how broad his knowledge and experience, no matter how ample his resources, must needs prove as he goes along the value of the individual steps of his progress, and often retrace them when he finds he is on a false path. More than that, he must disprove the false that appears to be true, and eliminate one by one the illusive beacons that might else forever lead him astray. These negative demonstrations, time-consuming as they necessarily are, are not striking to the observer from without; neither are the trenches that are destined to lead to the fall of a besieged town. One of the glaring faults that we have only recently begun to shed is that of demanding immediate positive results from research work. Let us divest ourselves of it altogether, and we shall then be reasonably sure that we are bearing well in mind the old motto, *Festina lente*. Not that the work of the institute need be exceptionally slow; indeed, we believe it has thus far been gratifyingly rapid, and we are confident that, if it is generously supported, it will not be found lagging.

THE DISTEMPER OF DOGS AND ITS MICROBE.

APART from the fact that physicians are generally lovers of the dog, it may be taken for granted that any advance in veterinary pathology and therapeutics, especially if it concerns an infectious disease, is of interest to our readers. Such an advance seems to have been made by Dr. S. Monckton Copeman, of the Brown Institution, in England, whose communication on the subject was recently transmitted to the Royal Society by Sir Michael Foster and appears in the number of the society's *Proceedings* dated January 19th.

Dr. Copeman states that his investigations into the bacteriology of the distemper have been in continuation of those begun in his laboratory at St. Thomas's Hospital about ten years ago by the late Everett Millais. He finds that the specific micro-organism of the disease is a

coccobacillus which stains with the ordinary aniline dyes, but is decolorized by Gram's method. It grows readily on agar-agar at the temperature of the body, and the individual colonies, when isolated by the method of plate culture, are grayish, glistening, and semi-transparent by reflected light and of a light brownish tint by transmitted light. It grows well in beef broth also. It is capable of growing, though rather slowly, on solidified serum and in milk, which does not become coagulated. On potato it develops with difficulty, but now and then, after some days' incubation, a moist-looking streak of a pale buff color may be observed. If gelatin is inoculated, the growth occurs slowly at the temperature of the room, and after a time the medium tends to become liquefied. Its growth on agar-agar may be carried on for many generations, but after about twelve removes its morphological and biological characteristics are found to have been somewhat altered. So, also, its pathogenic properties seem to be gradually weakened, but its virulence may be regenerated by repeated intraperitoneal inoculations of the guinea-pig.

By heating a broth culture of the bacillus to 140° F. and keeping it at that temperature for half an hour, subsequently adding a little carbolic acid as a preservative one may obtain a prophylactic product which acts against the distemper like those of Haffkine and Wright against the plague and typhoid fever, respectively. This preventive may be standardized after the manner of Wright. The prophylactic dose must vary according to the size of the dog. In three instances the author has found that the subcutaneous injection of half a drachm of the sterilized culture appeared sufficient to protect fox-terrier puppies weighing about forty-seven ounces against the distemper, while an unprotected puppy of the same batch contracted the disease from an affected dog. The author is not prepared to make a definite statement as to the length of time for which the protection lasts, but he says that experiments on a large scale are being carried on by dog-breeders in Great Britain, in Germany, and in America.

THE RELATIVE VALUE OF LAW AND LIFE.

IN a recent case in Philadelphia a physician has been subpoenaed to appear as a witness, and being half an hour late, was fined ten dollars by the judge. The physician explained that he was in attendance on a patient and that he had paid an urgent and necessary visit before going to court, hence his detention. The judge

however, though the fine was eventually remitted on the ground that the case was one of diphtheria and a matter of life and death, held that the physician's first duty was to the court. Harsh as this statement may appear, it seems to us that the judge's side of the question must not be lost sight of; for the law must guard itself against allowing its claim to paramount obedience to be disregarded, and itself imposed upon under a plea of professional engagement, by a physician as well as by any other member of the community.

But, if the newspaper report is to be believed, the judge went further, by giving utterance to the *obiter dictum* that "it was better that a patient should die than that the commonwealth should be treated with contempt." This is a most dangerous doctrine, intolerably subversive of the rights of the individual and the sacredness of life, and one which should be emphatically repudiated. In this particular instance, it might, perhaps (we know not), be urged that the physician in question could have paid his professional visit earlier, due notice of his court summons having been afforded, or that he might, in view of the occasion, have arranged for that particular visit to be paid by a brother practitioner; but it is easily conceivable that the circumstance might occur under conditions in which no loophole of escape from the dilemma of a choice between duty to life or to the commonwealth would be forthcoming, *e. g.*, the case of a country practitioner in an isolated district, or of an obstetrician or surgeon in the midst of a confinement or an emergency operation. Under such circumstances we think that the public conscience would repudiate an attempt to apply the judge's dictum with abhorrence. It must be remembered that it is primarily the individuals that confer rights and impose obligations on the community, not the reverse.

THE LATE DR. HORACE GREEN.

WE are glad to be able to record that on Thursday evening, the 7th inst., a bust of the late Dr. Green was presented to the New York Academy of Medicine by one of its ex-presidents, Dr. D. B. St. John Roosa. Tardy as it is, this is a graceful recognition of Dr. Green's early achievements in laryngology which in some degree makes amends for the contempt that was visited on him before his death.

BLOODLETTING IN HEAT FEVER.

FROM time to time accounts appear of beneficial results from the almost obsolete procedure of bloodletting. Klein, of Giessen (*Münchener medicinische Wochenschrift*, 1900, No. 27; *Wiener klinische Wochenschrift*, December 13th), reports the case of a powerful stoker on a ocean steamship who was overcome by heat. The unconsciousness and general spasms proved refractory to the usual remedies, and signs of increasing cardiac weakness were observed. Between six and seven ounces of blood was drawn, and the man's life was saved.

THE ANTIQUITY OF SYPHILIS.

THE much disputed antiquity of syphilis seems to have been supported recently by Zambaco Pacho, who, in his own name and that of M. Fouquet (*Revue médico-pharmaceutique*, 1900, No. 15; *Progrès médical belge*, January 1st), declared concerning certain bony specimens more than eight thousand years old, from Negadadus, Abydos, Thebes, and Beit-Allam, that they bore traces of lesions which they could attribute only to syphilis.

POISONING WITH NITRATE OF SILVER.

AT a recent meeting of the Berlin Psychiatric Society (*Deutsche Medizinische Zeitung*, January 10th) Dr. Max Edel remarked upon the rarity of poisoning from the use of the stick of lunar caustic, an occurrence which, he said, was chiefly the result of the stick's breaking while it was being used in the mouth, and the detached fragments being swallowed. He reported the case of an insane man who had swallowed three sticks with suicidal intent. In three days after his admission into an asylum he was attacked with fibrinous pneumonia, and died in a few days more, after persistent high fever and delirium. At the outset the breath was fetid and there was diarrhoea with whitish flocculi resembling curdled milk.

HEMIPLEGIA AS THE OCCASION OF RECOVERY FROM HEREDITARY EPILEPSY.

EPILEPSY is more apt to result from cerebral hæmorrhage than to yield to it. Nevertheless, Brunet (*Archives de neurologie*, ix, 51; *Gazette hebdomadaire de médecine et de chirurgie*, November 4th) reports a case in which the convulsive seizures had occurred about once a month. After a more than usually violent paroxysm the patient, a woman, was seized with partial left hemiplegia, after which the attacks gradually diminished in frequency, and for twenty years, up to the time of her death, there were no more. The epilepsy had lasted for fifty years when it was blotted out by the apoplectic stroke.

MOVABLE LIVER.

THERE are recorded cases of lobulation of the liver due to tight lacing, with decided depression of the artificial lobule. Marked mobility of the organ as a whole, however, seems to be of rarer occurrence. A case is related by Dibajlow (*Jeschenedelnik*, 1900, No. 33; *Deutsche Medizinische Zeitung*, December 10th) as having occurred in an unmarried woman thirty-four years old. The liver could be moved freely without pain. There were no symptoms, but the patient had applied for treatment under the idea that she had an ovarian cyst. An anomaly of the suspensory apparatus seemed to be the cause of the abnormality.

News Items.

Society Meetings for the Coming Week:

MONDAY, February 11th: New York Academy of Medicine (Section in General Surgery); New York Academy of Sciences (Section in Chemistry and Technology); New York Medico-historical Society (private) (anniversary); New York Ophthalmological Society (private); Lenox Medical and Surgical Society, New York (private); Harlem Medical Association of the City of New York; Gynecological Society of Boston; Burlington, Vermont, Medical and Surgical Club; Norwalk, Connecticut, Medical Society (private).

TUESDAY, February 12th: New York Academy of Medicine (Section in Genito-urinary Surgery); New York Medical Union (private); New York Obstetrical Society (private); Buffalo Academy of Medicine (Section in Medicine); Kings County, N. Y., Medical Association; Rome, N. Y., Medical Society; Medical Society of the County of Rensselaer, N. Y.; Newark (private) and Trenton, N. J., Medical Associations; Clinical Society of the Elizabeth, N. J., General Hospital and Dispensary; Northwestern Medical Society of Philadelphia; Practitioner's Club, Richmond, Kentucky; Richmond, Virginia, Academy of Medicine and Surgery.

WEDNESDAY, February 13th: New York Pathological Society; New York Surgical Society; American Microscopical Society of the City of New York; Society for Medical Progress, New York; Medical Societies of the Counties of Albany and Allegany (quarterly), N. Y.; Pittsfield, Massachusetts, Medical Association (private); Franklin, Massachusetts, District Medical Society (quarterly—Greenfield); Philadelphia County Medical Society.

THURSDAY, February 14th: Society of Medical Jurisprudence and State Medicine, New York; Brooklyn Pathological Society; New York Laryngological Society; Medical Society of the County of Cayuga, N. Y.; South Boston, Massachusetts, Medical Club (private); Pathological Society of Philadelphia.

FRIDAY, February 15th: New York Academy of Medicine (Section in Orthopedic Surgery); Clinical Society of the New York Post-graduate Medical School and Hospital; Baltimore Clinical Society; Chicago Gynecological Society.

Infectious Diseases in New York:

We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported for the two weeks ending February 2, 1901:

DISEASES.	Week end'g Jan. 26.		Week end'g Feb. 2.	
	Cases.	Deaths.	Cases.	Deaths.
Typhoid fever.....	33	12	27	15
Scarlet fever.....	329	22	326	14
Cer.-spinal men'gitis..	0	0	0	0
Measles.....	110	2	116	2
Diphtheria and croup.	332	52	361	40
Small-pox.....	11	1	50	2
Tuberculosis.....	331	185	282	90

Marine-Hospital Service:

Official List of the Changes of Stations and Duties of Commissioned and Non-Commissioned Officers of the United States Marine Hospital Service for the Seven Days ending January 31, 1901:

- CORPUT, G. M., Assistant Surgeon. To proceed to Cleveland and assume temporary command of the service during the absence of Surgeon W. J. PETTUS.
- McINTOSH, W. P., Surgeon. To proceed to Jeffersonville, Georgia, for special temporary duty.
- McMULLEN, JOHN, Assistant Surgeon. Upon expiration of leave of absence, to proceed to Wilmington, N. C., and assume temporary command of the service during the absence of Surgeon T. B. PERRY.
- PERRY, T. B., Surgeon. Granted leave of absence for thirty days from February 11th.

Board Convened.

Board convened to meet at Washington, D. C., on Tuesday, February 5, 1901, for the physical examination of Second Assistant Engineer R. F. HALPIN, R. C. S. Detail for the board: Surgeon PRESTON H. BAILHACHE, chairman; Surgeon G. T. VAUGHAN and Assistant Surgeon B. S. WARREN, recorder.

Marine-Hospital Service Health Reports:

The following cases of small-pox, yellow fever, cholera, and plague, were reported to the surgeon-general during the week ending February 2, 1901:

Smallpox—United States.

Washington, District of Columbia.....	Jan. 19-26.....	2 cases.
Jacksonville, Florida.....	Jan. 12-26.....	10 cases.
Chicago, Illinois.....	Jan. 19-26.....	25 cases. 1 death.
Michigan City, Indiana.....	Jan. 20-27.....	1 case.
Wichita, Kansas.....	Jan. 19-26.....	9 cases.
Lexington, Kentucky.....	Jan. 19-26.....	2 cases.
Shreveport, Louisiana.....	Jan. 19-26.....	5 cases.
New Orleans, Louisiana.....	Jan. 19-26.....	11 cases. 3 deaths.
Baltimore, Maryland.....	Jan. 19-26.....	1 case.
Erle, Pennsylvania.....	Jan. 19-26.....	1 case.
Pittsburgh, Pennsylvania.....	Jan. 19-26.....	2 cases.
Memphis, Tennessee.....	Jan. 19-26.....	8 cases.
Nashville, Tennessee.....	Jan. 19-26.....	4 cases.
Houston, Texas.....	Jan. 19-26.....	44 cases. 1 death.
Salt Lake City, Utah.....	Jan. 19-26.....	31 cases.
Milwaukee, Wisconsin.....	Jan. 19-26.....	1 case.

Smallpox—Foreign.

Antwerp, Belgium.....	Dec. 29-Jan. 5...	1 case.
Pernambuco, Brazil.....	Nov. 15-30.....	30 deaths.
Hong Kong, China.....	Dec. 3-15.....	1 case.
Alexandria, Egypt.....	Dec. 24-31.....	2 cases. 1 death.
London, England.....	Jan. 5-12.....	1 case.
Newcastle-on-Tyne, England.	Jan. 5-12.....	2 cases.
Paris, France.....	Jan. 5-12.....	11 deaths.
Bombay, India.....	Dec. 24-Jan. 1..	4 deaths.
Mexico, Mexico.....	Jan. 13-20.....	1 case.
Tuxpan, Mexico.....	Jan. 14-21.....	1 death.
Vera Cruz, Mexico.....	Jan. 6-13.....	3 cases.
Moscow, Russia.....	Dec. 22-Jan. 5..	9 cases. 4 deaths.
Odessa, Russia.....	Dec. 22-Jan. 12.	137 cases. 24 deaths.
St. Petersburg, Russia.....	Dec. 22-Jan. 5..	6 cases. 2 deaths.
Warsaw, Russia.....	Dec. 22-Jan. 5..	23 deaths.
Glasgow, Scotland.....	Jan. 11-18.....	121 cases. 2 deaths.

Yellow Fever.

Havana, Cuba.....	Jan. 12-19.....	2 deaths.
Vera Cruz, Mexico.....	Jan. 6-20.....	5 cases.

Cholera.

Bombay, India.....	Dec. 24-Jan. 1..	2 deaths.
Singapore, Straits Settlements.	Nov. 16-27.....	56 cases. 36 deaths.

Plague.

Bombay, India.....	Dec. 24-Jan. 1..	154 deaths.
Constantinople, Turkey.....	Jan. 7.....	1 death.

Naval Intelligence:

Official List of Changes in the Medical Corps of the United States Navy for the two weeks ending February 2, 1901:

- GROW, E. J., Assistant Surgeon. Detached from the *Culgo* and ordered to the *Glacier*, and also to duty in Olongapo Philippine Islands.
- McCLURG, W. A., Medical Inspector. Commissioned medical inspector from November 19, 1900.
- SHIFFERT, H. O., Assistant Surgeon. Ordered to the *Franklin*.

Army Intelligence:

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from January 19 to February 2, 1901:

- BISPHAM, WILLIAM N., First Lieutenant and Assistant Surgeon, United States Army, will proceed to Cabana Barracks, Havana, for duty as surgeon, relieving H. M. JAMES, Acting Assistant Surgeon.
- Hess, Louis T., First Lieutenant and Assistant Surgeon, United States Army, is relieved from further duty the Division of the Philippines.
- HOFF, JOHN VAN R., Major and Surgeon, United States Army is detailed as a member of the board of officers appointed to meet in Washington for the examination of office for promotion, vice DALLAS BACHE, Colonel and Assistant Surgeon-General.
- LAGARDE, LOUIS A., Major and Surgeon, United States Army is detailed as a member of the board of officers appointed

to meet in Washington for the examination of officers for promotion, *vice* CHARLES SMART, Lieutenant-Colonel and Deputy Surgeon-General.

REILLY, ROBERT M., Lieutenant-Colonel and Deputy Surgeon-General, United States Army, is detailed as a member of the board of officers appointed to meet in Fort Monroe, Virginia, for the examination of officers for promotion, *vice* CHARLES N. BARNEY, Acting Assistant Surgeon.

OLHEMUS, ADRIAN S., Captain and Assistant Surgeon, will proceed to Fort Ridley, Kansas, for temporary duty during the absence of CHARLES E. WOODRUFF, Captain and Assistant Surgeon.

A Bull's Eye.—The *Charlotte Medical Journal* for January is responsible for the assertion that "nearly one half the men and women in the country die while they are children."

Chinatown, in San Francisco, is to be cleaned up. The streets are to be bitumenized and the entire district fumigated and thoroughly cleansed.

Civil Service Appointment.—Dr. George Pfromm has been appointed medical examiner of the local civil service board in Philadelphia.

The State Board of Health may be Abolished.—The bill abolishing the New York State Board of Health and establishing a single-headed commission has been reported favorably in the senate.

The Oldest People in the World.—According to the report of a committee of the Hundred Year Club, the oldest man now living is Izai Rodefsty, of Moscow, Russia, who is in his hundred and thirty-sixth year, and Mrs. Nancy Hollifield, of Battle Creek, Mich., who is 117.

An Automobile Service for Physicians.—The Detroit Physician Service Company is a new institution that will start in business in Detroit shortly. The company proposes to furnish an automobile business for physicians for a stated amount every month.

A New Medical Building for the University of Pennsylvania.—A movement is on foot at the University of Pennsylvania toward the erection of a new medical building. The present building was one of the original buildings, erected in 1873. It has little architectural beauty and none of the modern improvements.

The Alumni of Mt. Sinai Hospital will give their annual dinner at the Arena, 39 West Thirty-first Street, New York City, on Wednesday evening, February 20th, at 7 o'clock. The secretary of the association, Dr. Charles A. Elsberg, 105 East Fifty-seventh Street, has charge of the tickets.

Yellow Fever in Cuba Decreasing.—The report of C. Gorgas, chief sanitary officer at Havana, for the month of December makes a very gratifying showing. The total number of deaths was 485, the smallest for any December in ten years. Major Gorgas calls attention to the marked decrease in the number of yellow fever cases.

To Regulate the Practice of Medicine in Kansas.—A bill creating a State board of medical examiners has been introduced into the Kansas legislature by Dr. R. W. Maintz, a member of that body. Dr. Maintz has also introduced two bills intended to promote the accuracy of the statistical work of the public health bureaus, by re-

quiring reports by physicians of deaths and births, and by court clerks and judges of marriages and divorces.

A Would-be Medical Trading Corporation Squelched.—A *pro forma* decree of incorporation was denied the Red Cross Medical Association of St. Louis on January 23d by Judge Fisher. The referee, to whom the matter was referred, reported that the statute under which the association sought to incorporate contained no provision for the incorporation of a medical society. The purpose of the association was to supply members with medical treatment on their paying monthly dues.

Proposed Change in Minnesota's Marriage Laws.—Dr. E. V. Clinton, of Howard Lake, has introduced in the Minnesota legislature a bill which provides that a marriage shall not be allowed between two persons where either one is, or has been, subject to fits of any kind, insanity, etc., and that a certificate of a physician showing that the applicants are fit to enter the married state shall accompany all applications for a marriage license. The penalty for a violation of the law is a fine of \$1,000 or five years in the penitentiary, or both.

Readjustment of Medical Studies in Pennsylvania.—Provost Harrison, of the University of Pennsylvania, in his annual report, announces a readjustment of the studies required of students for the degree of doctor of medicine, by which they may complete the course in arts or science and obtain the medical degree in seven years. By pursuing the plan outlined, the course in medicine is made a three, instead of four, years' course. The plan provides that under certain conditions a senior in college may be a freshman in the medical school.

To Build a Home for Trained Nurses.—An entertainment is to be given at the Waldorf-Astoria, on the evening of February 16th, by the Guild of St. Barnabas for Trained Nurses, the proceeds of which will be devoted to securing a house where its members, when not on duty, can find a comfortable home, with a view to their mental, moral, and physical betterment. A number of the leading society women have taken a lively interest in this entertainment. The programme for the evening is under the directorship of Mr. Bruno Huhn. Tickets may be had of Mrs. A. E. Gallant at 60 West Fifty-sixth Street.

A Tuberculosis Conference at Ottawa.—A conference to take concerted action in order to overcome the ravages of tuberculosis will be held at Ottawa, Ont., on February 14th. The conference will last for a day. His Excellency the Governor-general is honorary president and Sir James Grant president. A series of resolutions will be drawn up and a general discussion take place. It is expected that there will be a large attendance. The Governor-general will preside and will deliver an address. Sir James Grant, president of the council for Canada, and others, will speak.

The Medical Society of City Hospital Alumni, St. Louis.—At the last meeting, on Thursday evening, the 7th inst., Dr. George Homan read a paper entitled *Our Daily Bread*, and Dr. Given Campbell presented the following cases: Lingual hemiatrophy and facial spasm; motor aphasia; and cerebral tumor.

The Jackson County Medical Society was organized at Jackson, Mich., on January 24th, with Dr. A. E. Bulson as president.

The St. Louis Medical Society of Missouri.—At the last regular meeting, on Saturday evening, the 2d inst., Dr. C. Barck read a paper entitled A Case of Otitic Cerebellar Abscess, Sinus Thrombosis, and Commencing Deep Cervical Abscess.

The Baltimore Medical and Surgical Association met on January 28th and the following papers were presented concerning grippe: The Causes and Distribution of Grippe, by Dr. W. Royal Stokes; The Effects of Grippe on the Naso-pharynx, by Dr. S. K. Merrick; The Grippe as Seen in Children, by Dr. Charles W. Witchell; The Broncho-pulmonary Symptoms of Grippe and their Treatment, by Dr. David Street; The Nervous Sequelæ of Grippe, by Dr. Charles G. Hill, president of the association.

The Associated Physicians of Long Island.—The third annual meeting of the Associated Physicians of Long Island was held in the rooms of the Medical Society of the County of Kings, Brooklyn, on January 26th, a large number of members being in attendance. The following officers were elected: President, Dr. William B. Gibson, of Huntington; first vice-president, Dr. Calvin F. Barker, of Brooklyn; second vice-president, Dr. James S. Cooley, of Glen Cove; third vice-president, Dr. William H. Ross, of Brooklyn; secretary, Dr. James C. Hancock, of Brooklyn, and treasurer, Dr. John P. Heyden, of Northport. Dr. Elias H. Bartley read a paper on The Science of Feeding in Acute Fevers. Nineteen new members were elected. In the evening the annual dinner was given at the Oxford Club.

The Cleveland Medical Society.—The ninth annual meeting of the Cleveland Medical Society was held recently and the following officers for the ensuing year elected: President, Dr. Charles F. Hoover; first vice-president, Dr. H. W. Rogers; second vice-president, Dr. Robert Pollock; secretary, Dr. J. N. Lenker; treasurer, Dr. J. M. Ingersoll; censors, Dr. C. A. Hamann, Dr. F. C. Herrick, Dr. H. C. Ballard, Dr. D. S. Hanson, and Dr. J. J. Thomas; trustees, Dr. J. H. Belt, Dr. W. A. Knowlton, and Dr. O. B. Campbell, their term of office expiring in 1904. Dr. W. H. Humiston read a paper on Multiple Fibroma of the Uterus, and Dr. G. W. Crile one on Medullary Narcosis Based on Experimental and Clinical Evidence, showing the effects of cocaine when used as an anæsthetic. Dr. H. W. Quirk presented a case of malignant growth on the back to the society.

The New York Academy of Medicine.—At the next meeting of the Section in Surgery, on Monday evening, the 11th inst., Dr. John Rogers, Jr., will read a paper entitled Experience with Tracheotomy.

At the next meeting of the Section in Otolaryngology, on Wednesday evening, the 13th inst., the following papers will be read: The Early Operative Treatment of Mastoiditis, by Dr. E. B. Dench, and A Case of Cerebellar Abscess Complicating Acute Suppuration of the Mastoid, by Dr. Wendell C. Phillips. Cases will be presented and new instruments and specimens will be exhibited.

At the next meeting of the Section in Pædiatrics, on Thursday, the 14th inst., the order for the evening will be as follows: Vaccination Clinically Considered, by Dr. Frank S. Fielder; Remarks on the Preparation of Vaccine, by Dr. John H. Huddleston; Remarks on Specific Organisms in Vaccinia, by Dr. Anna W. Wil-

liams; Report of a Case of Vomitus Nervosus associated with General Hysteria, with presentation of the patient, by Dr. Louis Fischer; Report of a Case of Diabetes in an Infant, by Dr. William E. Young; and A Simple Apparatus for Modifying Cow's Milk, by Dr. C. Herrmann.

Insanitary Conditions in Sing Sing Prison.—A committee of the Prison Association, aided by an expert sanitary engineer, has investigated the sanitary condition of Sing Sing prison and has made a report to the association strongly condemning the insanitary conditions prevailing in the institution. It is understood that vigorous efforts will be made to have the legislature authorize the destruction of the prison and the erection of another in a more suitable site, with due regard for sanitary considerations. The principal indictments against the prison are its location on the river bank but five feet above tide water, and on a moist and polluted soil, its lack of ventilation, its overcrowding, its faulty construction, which shuts out sunlight as well as air, and its plumbing arrangements throughout. The matter has been laid before the New York State board of health.

The Bell Bill Amended.—As the result of a conference between the chairman of the committee on legislation of the New York Medical Society, the chairman of the committee on legislation of the New York State Medical Association, the chairman of the committee of the New York Medical Association, and Assemblyman Bell, the father of the bill, the Bell bill has been changed so that the amendment now reads as follows: "The construction of this article is that any person shall be regarded as practising medicine within the meaning of this act who shall give treatment to any other person by the use of any remedy, agent, or method whatsoever whether with or without the use of any medicine or instruments or other appliances for the relief or cure of any wound or fracture, bodily injury, or infirmity physical or mental disease." The Bell bill originally made it a misdemeanor for any person to recommend or advise any person to take any medicine, or to take any thing, or to undergo any kind of regimen or treatment whatever. The New York State Medical Association vigorously combated this bill as interfering with the individual rights of citizens. At the second hearing, on February 6th, an amendment was also made which practically exempts patent medicines from the action of the measure.

A State Hospital for Missouri.—Health Commissioner Max C. Starkloff has sent to Senator C. A. Smith at Jefferson City the draft of a bill for the establishment of a State hospital, accompanied by a letter explaining the importance of having a hospital for the benefit of the sick poor of Missouri. Mr. Starkloff urges that it is unjust to St. Louis to be compelled to provide for thousands of pauper patients who go there each year.

The bill provides that the hospital shall be located or near St. Louis, and shall be managed by a board of nine directors, to be appointed by the Governor, the board to consist of four physicians and five business men. The bill also provides for the selecting of a superintendent and sixteen consulting physicians.

The proposed hospital is to be known as the Missouri General Hospital, and the sick poor of the State may be sent to it by the county courts of their respective counties.

The Fitch Accident Hospital to Close.—After a meeting of the Charity Organization Society, Dr. Roswell Park made an announcement that the accusations brought against the staff of the Fitch Accident Hospital, Buffalo, charging them with incompetency and brutality, had not been verified. There will be no investigation and no dismissals. The hospital will be closed indefinitely on March 1st, on account of financial difficulties.

A Government Hospital at Cape Nome.—The terrible sufferings of the inhabitants at Cape Nome has been the cause of a bill being introduced in Congress asking for the appropriation of \$20,000 for a government hospital. Dr. Nininger, a leading physician of that place, in a report to Senator Mason, said that the rates in the Nome hospital were so high that men could not pay even for a bed in the destitute wards. The bill has been referred to the committee on territories, and Senator Mason and Dr. Nininger will make a plea for its passage.

Hospital Staff Changes.—Dr. George W. Graben-tatter has resigned from the staff of the Fitch Hospital.—The hospital board of Columbian University, Washington, held a meeting on January 5th, and the following officers were elected for the ensuing year: Dr. F. A. King, president; Rev. Dr. S. H. Greene, vice-president; Mr. S. W. Woodward, treasurer, and Dr. E. A. De Schweintz, secretary.—At the Emergency Hospital in Washington, Dr. Clifford Spiro has been promoted from the rank of senior assistant resident physician to that of resident physician, and Dr. R. S. Beale has become senior assistant, and Dr. Boyd Dixon, of Columbian University, has been appointed junior assistant.—Dr. Mary M. Wolfe, resident physician of the Women's Department of the State Hospital for the Insane at Norristown, Pa., has entered on her new duties. It is likely that Dr. Florence Hull Watson will be chosen to fill the place made vacant by her promotion, that of third assistant.—On January 26th, twenty physicians met at St. Joseph's Sanitarium, Mt. Clemens, Mich., and organized a staff to be known as St. Joseph's Sanitarium staff of physicians and surgeons.

Hospital Reports.—The following data are gleaned from the annual reports of the several hospitals named: During the year 1900, 2,619 patients have been admitted to the Royal Victorian Hospital at Montreal, and the death rate was 4.95 per cent. The total cost per day per patient has been \$1.47, as against \$1.55 last year. The income for the year was \$129,570.34, while the ordinary expenditure amounted to \$99,208.62, the balance of \$30,361.72 being applied toward the cost of the new outpatient department and the power house and laundry building. By their erection the hospital has incurred a debt of \$75,000, which will be extinguished during the next few years by the savings from income, if it be not otherwise provided for.—During 1900 there were twenty-nine more private medical patients, and forty-nine less ward patients, than the previous year at the Rochester, N. Y., city hospital; nine more births, 126 less private surgical patients, and thirty-three more ward surgical patients. Eighty-nine different physicians were in attendance upon private patients during the year, and there were over 450 operations.—The number of patients received at the German Hospital, Brooklyn, from December 1, 1899, to December 31, 1900, has

been 822. Of these 447 were male and 375 female. The number of patients discharged as cured was 485; convalescents, 175; uncured, 37; died, 95; surgical treatment was accorded 596 patients; medicinal treatment, 226; 87 accident cases were treated. The total receipts from patients amount to \$16,105.97. The total number of attendants at the hospital was fifty, including three medical students, two surgeons, two physicians, and one druggist. The receipts from January 1, 1900, to December 31, 1900, were \$24,758.87, and expenditures, \$46,040.03, leaving the cash on hand \$34,614.09.—The Milwaukee (Wis.) Hospital for Insane recently presented its annual report, which shows the average number of patients under treatment daily was 431. The percentage of recoveries to admissions during the biennial period was 34½ per cent., and the ratio of deaths to the whole number of patients treated was 6½ per cent.—The annual report of the Episcopal Eye, Ear, and Throat Hospital, Washington, D. C., shows that the total expenses of the year were \$4,947.70. The report of the attending medical staff showed an increase of visits made to the hospital by patients of 2,975 over the previous year. There were 221 patients admitted to the hospital, of which 101 were treated free of charge, and 307 operations were performed, nearly all being successful.

Hospital Buildings and Endowments.—Steps have been taken looking toward the erection of a hospital building in Port Huron, Mich., the Academy of Medicine being the active agent in the matter.—The St. Paul, Minn., chamber of commerce has adopted resolutions favoring the establishment of a State sanitarium for consumptives.—Bids have been asked for by the War Department for the erection of a twelve-bed hospital at Fort Keogh, Mont.—The Clara Barton Hospital Association has been incorporated in San Francisco with a capital stock of \$50,000, \$7,000 of which is paid up. The incorporation of the company is the result of a controversy concerning the management of the Waldeck sanatorium, and the physicians formerly connected with that institution will have control of the new hospital. The directors of the association are: Dr. J. Henry Barbat, Dr. George H. Evans, Dr. E. G. Frisbie, Dr. Charles A. Dozier, Dr. Elmer E. Kelly, Dr. H. B. Kugeler, and Dr. F. B. Carpenter. Of these, Dr. Barbat and Dr. Carpenter were formerly members of the corporation conducting the Waldeck sanatorium, and Dr. Kelly is at present a member.—The Albany hospital has received a donation of \$500 for the maintenance of a bed for the treatment of any needy resident of Chenango county standing in need of surgical treatment.—Five bills have been introduced in the California legislature making appropriations for various improvements in and additions to the Southern California asylum for the insane. The additions contemplated include a \$50,000 tuberculosis hospital and a \$92,000 central administration building.—An appropriation has been made by the War Department for a chapel, reading room, and library for the general hospital at the Presidio, San Francisco, Cal.—In his annual report the health commissioner of the city of Baltimore urgently insists that the city should promptly provide a hospital for infectious diseases.—A similar recommendation has been made by the hospital committee of the board of supervisors at San Francisco.—Health Commissioner Wende, of Buffalo, keeps up his agitation for a quarantine, or detention, hospital for Erie county, and the indications are that he will eventually carry his point.—

The House of Mercy, Pittsfield, Mass., has received a donation of \$50,000 for a new hospital building.—The fact that Boston is not adequately provided in the matter of a reception hospital for infectious diseases is attracting considerable attention in the lay press.

Births, Marriages, and Deaths.

Born.

EDIE.—In San Francisco, on Friday, January 11th, to Dr. Guy L. Edie, United States Army, and Mrs. Edie, a daughter.

Married.

ATKINSON—TAYLOR.—In Norfolk, Virginia, on Wednesday, January 30th, Dr. A. Duval Atkinson, of Baltimore, and Miss Patty Taylor.

BUTLER—HUBBARD.—In Boston, on Thursday, January 31st, Dr. Charles S. Butler and Miss Margaret Parker Hubbard.

CONOVER—FRITSCH.—In New York, on Wednesday, January 30th, Dr. John Hamilton Potter Conover and Miss Abigail Henriques Fritsch.

ECK—RHOADES.—In Pottstown, Pennsylvania, on Tuesday, January 29th, Dr. William H. Eck and Miss Annie B. Rhoades.

LAMB—KEEN.—In Washington, on Tuesday, February 5th, Dr. Robert Scott Lamb and Miss Sarah Keen.

LUCY—LEWIS.—In Denver, on Thursday, January 24th, Dr. Daniel R. Lucy and Miss Margaret Lewis.

PITTMAN—CASON.—In Marietta, Georgia, on Thursday, January 24th, Dr. James Hardy Pittman, of Jacksonville, Florida, and Miss Myrtice Barnett Cason.

PLATT—TISDALE.—In Astoria, N. Y., on Monday, February 4th, Dr. Clarence N. Platt and Miss Edith Tisdale.

SAPPINGTON—ROBERTSON.—In Elmira, N. Y., on Saturday, January 19th, Dr. William Fulford Sappington, of Hartford County, Maryland, and Miss Florence Valiant Robertson.

Died.

BARR.—In Cleveland, on Thursday, January 24th, Dr. Frank H. Barr, in the fifty-first year of his age.

BAXTER.—In Philadelphia, on Friday, February 1st, Dr. Henry F. Baxter, in the fifty-eighth year of his age.

BEACH.—In Vandalia, Illinois, on Wednesday, January 23d, Dr. R. E. Beach, aged fifty-one years.

BOSLEY.—In Baltimore, on Friday, January 25th, Dr. Grafton Marsh Bosley, aged seventy-six years.

CHAMBERLAINE.—In Easton, Maryland, on Wednesday, January 30th, Dr. Joseph Ennalls Meuse Chamberlaine, in the seventy-fifth year of his age.

GRIGGS.—In Newark, N. J., on Friday, February 1st, Dr. Stephen Chandler Griggs, aged eighty-two years.

HAGAN.—In Los Angeles, on Wednesday, January 23d, Dr. Morton Hagan, formerly of the United States Army, in the sixty-ninth year of his age.

HOUSTON.—In Atlanta, on Sunday, January 27th, Dr. A. P. Houston, of Clarksville, Georgia, aged sixty-nine years.

JEWETT.—In Cortland, N. Y., on Wednesday, January 30th, Dr. Homer O. Jewett, in the eighty-second year of his age.

LINES.—In Vernon, Vermont, on Monday, January 28th, Dr. Oliver Todd Lines, of Brooklyn, in the eighty-eighth year of his age.

MARSHALL.—In West Chester, Pennsylvania, on Monday, January 28th, Dr. Edward James Marshall, in the sixtieth year of his age.

MILLER.—In New York, on Monday, January 28th, Dr. Theodore DeClermont Miller, aged fifty-nine years.

NEVISON.—In Cleveland, on Sunday, January 27th, Dr. William H. Nevison.

O'BRIEN.—In Pittsburgh, on Monday, January 28th, Dr. John Henry O'Brien, aged forty-one years.

PIGOTT.—In Annapolis, Maryland, on Thursday, January 31st, Dr. Michael Royston Pigott, United States Navy, in the thirty-sixth year of his age.

ROSS.—In Champaign, Illinois, on Thursday, January 24th, Dr. W. Frank Ross, aged forty-four years.

SHURTLIFF.—In Brookline, Massachusetts, on Sunday, January 27th, Dr. Augustine Shurtliff, in the seventy-fifth year of his age.

WINDER.—In Brooklyn, on Friday, January 25th, Dr. Guthrie R. Winder.

Pith of Current Literature.

Medical Record, February 2, 1901.

Radical Cure of Inguinal Hernia. By Dr. A. M. Phelps.—The author draws a line of distinction between Bassini's and Halsted's operations. They are both original and each differs from the other. The points of originality in the author's operation are: 1. The reproduction of large masses of inflammatory material to restore the abdominal parietes, and the introduction of a fine silver-wire filigree throughout the entire inguinal canal, over the transversalis fascia, which adds to the strength of the weakened abdominal parietes and prevents the new material from stretching. 2. Cutting off the hernial sac, and retreating from the operation exactly as from any abdominal operation, stitching up the peritonæum and transversalis fascia with a continued suture of fine silver wire. Drainage should be avoided if possible; but, if necessary in thick abdominal walls with much fat, a glass drain is the best.

The Treatment of Puerperal Fever. By Dr. H. J. Boldt.—According to the author's classification, the main varieties of puerperal fever are: Acute bacteræmia, chronic bacteræmia, sapræmia, and septic infection (local septic infection). His reasons for using these terms may be found in a previous article (Septicæmia and Pyæmia, etc.) printed in the *New York Medical Journal* on January 26, 1901. The author insists upon an observance of the rules of antiseptics in obstetrics. The patient, in puerperal fever, should, first of all, have perfect rest. Next, attention should be directed to the seat of primary entrance of the fever-producing agents. The parts should be wiped with absorbent cotton steeped in some antiseptic solution, and dried and dusted with one of the so-called antiseptic powders. No medicament which produces an escharotic effect should be used. When the seat of infection is in the uterus, this organ is found enlarged and relaxed, and the cervical canal generally admits of the introduction of the index finger. The uterus should be cleaned of all foreign material under antiseptic precautions, and the author advises discarding the curette for this purpose. An intrauterine douche is advisable before and after manipulations within the uterus. It is inadvisable to place gauze in the uterus for the sole purpose of draining off secretions; and as for curetting of the uterus, that treatment, according to the author, has been misused more than any other. Vaporization is more effective on infection elements in the deeper structures of the uterus, and is the treatment *par excellence* in septic infection of the uterus.

An Operation for the Relief of Stoppage of the Tear Passage, Abscess of the Sac, etc. By Dr. Erasmus E. Pond.—The operation proposed by the author is a simple one. A long silver wire threaded with a coarse silk string is passed through the canal into the nose where the end is seized with a pair of forceps and drawn out through the nostril. Both ends of the string are then tied together, and the string is drawn through the nose two or three times a day for about a week. As the string causes no solution of continuity in the mucous membrane, there can be no stricture, hence the opening remains permanent. In the author's practice the result have been very gratifying.

The Malarial Mosquito on the Susquehanna. By Dr. Harvey E. Bashmore.

Placenta Prævia or Detached Placenta. By Dr. George W. Squires.

Medical News, February 2, 1901.

Fatty Degeneration of the Heart. By Dr. Thomas E. Satterthwaite.—This is a common affection, according to the author, though it is not to be classed as a disease *sui generis*, but rather as a metamorphosis or process attending on loss of compensation in valvular diseases, but also nearly as often on non-valvular diseases. It is caused by fevers, toxæmia, dyscrasias, disorders of nutrition, and mechanical injuries, but it may also be a physiological process. In the early stage the prognosis is best for complete recovery—that is, if the patient does not yield to the primary disease. In the intermediate stage the prognosis is not so good for the absolute arrest of the fatty process, but the functions of the heart may be so improved that the patient should be able to resume his former work and enjoy a fair degree of health for an indefinite period. We may expect a physiological, if not a pathological, cure. In the third or final stage, which is marked by such profound implication of the internal viscera that their functions are in abeyance, the prognosis is always unfavorable. The end will rarely be delayed beyond a few months.

A Case of Puerperal Sepsis from Retained Lochia (Lochiometra), with Remarks. By Dr. George P. Shears.—With reference to the ætiology of these cases, the author asks the question, "How do the bacteria gain access to the genital canal?" Antelexion of the puerperal uterus, and consequent lochial retention, can be regarded only as predisposing. We must account for the presence of the offending organisms. Infection may be transmitted in the usual way, *i. e.*, by the examining finger, instruments, etc., but, since all air contains saprophytes, the author considers it reasonable to suppose that decomposition of clots and other débris may be the result of the admission of air to the vagina and uterus, especially during manipulations in the third stage of labor. While the rigorous employment of every method for the exclusion of bacteria is of the first importance, no method of prophylaxis or treatment can be regarded as even approximately correct which does not include a careful study of the predisposing as well as the primary causes of infection.

Medical and Sociological Aspects of the Galveston Storm. By Dr. H. A. West.—The author attributes the appalling loss of life chiefly to the failure by those who lived in the vicinity of the beach front to recognize the gravity of the situation until it was too late. After the storm, the conditions deleterious to public health that prevailed were: (1) Overcrowding; (2) filth and general impairment of sanitation; (3) excessively high temperature; (4) an enormous increase of disease-bearing insects, especially flies; (5) imperfect water supply; defective sewage. The extensive prevalence of gastrointestinal disorders and typhoid fever indicates, in the author's opinion, the invasion of the food and water supply, as well as the atmosphere, with pathogenic microorganisms.

Infantilism. By Dr. W. T. English.—The author presents a highly interesting case of this affection. The changes that have come over the child during the eight months of treatment exemplify what can be done for these cases of myxœdematous retardation by the use of hyreoid. Muscles and mind are restored to activity and the faculty of speech recovered.

Boston Medical and Surgical Journal, January 31, 1901.

The Treatment of the Later Phases of Heart Diseases. By Dr. John L. Heffron.—By the expression

"the later phases of chronic heart disease," the author has in mind that period of time, short or long, after compensation has once failed. At that time treatment must be guided by (1) the condition of the heart; (2) the abnormal conditions resulting from a disturbed circulation, and (3) the general condition of the patient. Absolute rest in bed is the first indication; it relieves the heart physiologically of from ten to twenty contractions per minute, as compared with the usual conditions which prevail when one is simply "confined to his room." All visitors should be excluded. Elaterium, calomel, salines, are, in the order of preference, the drugs the author uses for the elimination of waste matter. The diminution of ingested fluids must be insisted upon. To relieve the distressing nervousness, ice-bags over the heart may suffice, but, these failing, codeine in one-half-grain doses, hypodermically, should be first tried, and then morphine. Cannabis indica, on occasion, will give most gratifying results. The diet should be carefully regulated, and substances which are bulky and of small nutritive value should be excluded. Predigested foods are of use, but the best results are produced by giving small portions at very frequent intervals. When cardiac dropsy is manifested, all three of the emunctories should be acted upon, though it has been frequently observed that digitalis and all diuretics will fail to act until relief is attained by mechanical means. The cabinet bath is of use. If digitalis is contra-indicated, caffeine will produce good results. Before resort to tapping is made, it is the author's practice, with all aseptic precautions, to puncture the skin of the dorsum of the foot and of the leg in many places. If, fortunately, a failing compensation is restored, the very condition of the prolongation of life is moderation.

Peritonsillar Abscess. By Dr. F. C. Cobb.—The author's object is to urge the use of a little more care and study in the relief of this disease. He believes that it results from infection by the germs of acute tonsillitis. The symptoms are chill, followed by fever and headache and pain referred to one side of the throat. Puncture, with the application of cocaine, is painless, and results in cure usually. Should there be no sign of pus in either pillar, the supratonsillar fossa must be sought as the most probable seat of the suppuration. On account of the great vessels lying in the pharyngomaxillary space, care must be used in the use of the knife. Left to themselves, these abscesses usually subside through rupture in from four to seven days. Several cases, however, are on record where the pus has made its way into the posterior portion of the pharyngomaxillary fossa, and so into the mediastinum, with fatal results.

Retropharyngeal Abscess in the Adult. By Dr. J. L. Goodale.—This is a case of tuberculous retropharyngeal lymphadenitis, ending in suppuration. No point of entrance for the infection was found.

Journal of the American Medical Association, February 2, 1901.

Mental Symptoms of Cerebral Syphilis. By Dr. James H. McBride.—Though there is frequently an incongruity between the conduct of an insane person and his pretensions, yet it is so marked in the syphilitic insane as to have a diagnostic significance. A quiet, apathetic, mildly varying condition, with long periods of confusion and dullness, occasional and sudden return of apparent sanity with depression or short attacks of hysteria and return to habitual mental state—these are

the symptoms of a very common type of syphilitic insanity. Insanity may occur very soon after the appearance of secondary symptoms. The author has seen it develop within six months. The author is not of those who assert that all parietic dementia is due to syphilis, and, though some forms of syphilitic insanity are certainly much like parietic dementia, the author believes that these cases are often due immediately to conditions that are alike. The intellectual man who has contracted syphilis is more liable to have his brain attacked than another man whose mental capacity is of a lower order.

A Report of Seven Operations for Brain Tumors and Cysts. By Dr. Hermann H. Hoppe.—Tumors of the cortex or subcortical region of any portion of the cerebral hemispheres which can be reached through the calvarium are operable. The author is opposed to the exploratory operation, and also the palliative operation for the relief of intracranial pressure. In his opinion, tubercles, if isolated and located so as to be operable, should be operated upon, other things being favorable. Metastatic carcinomata are inoperable.

The Skull and its Contents. By Dr. W. H. Earles.

Treatment of Typhoid Fever, with Bactericidal in Connection with other Agents, and some Consequent Deductions. By Dr. J. M. Peck.—The author believes that the results secured by the bath and intestinal antiseptics are the most favorable. He asserts that it is a mistake to check a diarrhoea in typhoid fever except by the use of a purgative or by a thorough washing with sterilized water. Results indicate that the chlorine solution has a beneficial effect in checking the production of the toxins, or in rendering them less active. The use of calomel prepares the way or acts as a stepping-stone for the chlorine.

Influenza Accompanied by Four Distinct Pneumonic Attacks. Otitis Media Purulenta and Cerebral Hyperæmia, Colitis, Inanition—Recovery. By Dr. Julius Ullman.

Aural Manifestations of Syphilis. By Dr. Francis R. Packard.—The author does not think that syphilis can be a very frequent source of ear disease. In going over the literature of the subject, however, one is impressed with the great variety of ear lesions which have been described as occasionally of syphilitic origin. To the author it seems very probable that many most obstinate cases which do not yield to local treatment may possibly be due to syphilis and only awaiting proper constitutional treatment.

Prevention of Intracranial and Intravenous Complications in Suppurative Diseases of the Ear. By Dr. J. H. Woodward.—The author insists upon rectification of abnormal states of the nose and throat as an indispensable preliminary to the prophylaxis of intracranial and intravenous complications of infectious pyogenic diseases of the ear.

The Cerebral Neurons in Relation to Memory and Electricity. By Sir James Grant, M. D.—In the examination of nerve power by electroneurotone currents, the author noted on several occasions, after a few weeks' application, quite a change in intellectual activity, as evidenced by improved memory. The currents were passed through the base of the brain, chiefly, by applications to the parotid regions on either side of the neck. The individuals operated on were over sixty years old.

Report of Two Cases of Afebrile Typhoid. By Dr. Charles J. Whalen.—The author gives two interesting cases of this affection which were brought to the atten-

tion of the profession by Liebermeister. He is convinced that the disease occurs in an endless number of types, and that the typhoid of to-day is not the typhoid of von Niemeyer, Trousseau, Flint, and others, for they portrayed a disease having a fairly constant train of symptoms, a fever with a characteristic course, and other equally important conditions varying. Certainly ambulatory and afebrile types of the disease must have been very rare or else were not diagnosticated in the practice of the older authors.

Philadelphia Medical Journal, February 2, 1901.

Scurvy, not Rheumatism. With a Report of Sixteen Cases of Infantile Scurvy. By Dr. J. P. Crozer Griffith.—The author's experience would seem to indicate that this affection is far more common in childhood than is generally supposed. Many of his cases bear out the common experience that rheumatism, more than any other disease, is erroneously diagnosed when scurvy is really the condition. Pain somewhere, generally in the legs, is oftenest first seen, and many diagnostic errors are due to this fact. There is no one dietetic fault which can be held responsible as the cause of scurvy, though it is oftenest found that commercial foods fed to scorbutic children constitute a powerful ætiologic factor. The treatment is simple and consists of a proper alteration of the diet; even without this, the administration of pure fruit juice is sufficient to work a cure. Only in cases where debility has grown extreme, or where intercurrent maladies exist, which possibly interfere with treatment, need a fatal result be feared. The diet should not be altered too quickly simply because of scurvy; a curable scurvy is preferable to a fatal diarrhoea—the result of a diet which may precipitate these.

Whey-cream Modifications in Infant Feeding. By Dr. Franklin W. White and Dr. Maynard Ladd.—The authors conclude that by the use of whey as a diluent of creams of various strengths, we are able to modify cow's milk so that its proportions of caseinogen and whey-proteids will closely correspond to the proportions present in human milk. The emulsions of fat in whey, barley water, gravity cream, and centrifugal cream mixtures were the same both macroscopically and microscopically. The authors assert that whey-cream mixtures yield a much finer, less bulky, and more digestible coagulum than plain, modified mixtures with the same total proteids.

Proper Methods of Handling Milk for Infant Feeding. By Dr. George Thomas Palmer.—In a brief and practical paper the author asserts that clean milk is far more important than any amount of modification, and he believes that such milk most certainly can be procured in all the large cities. Such a milk is far better than cooked milk. The methods in use at a certain Illinois farm are then detailed. The author is convinced that sterilization is simply a bridging-over of faults that should not have been committed. After trying a raw milk with the infants of the poor during a terribly hot season, and after having seen what can be done toward the preparation of a clean, pure milk, the author would banish forever sterilization or pasteurization on the same ground that he would banish formaldehyde or any milk preservative—on the ground that they are both injurious and unnecessary.

The Importance of Instruction in Medical Schools on the Modification of Milk for Prescription Feeding. By Dr. Andrew H. Whitridge.—The milk laboratories that have been established in many cities of the United

states have done much to further the scientific feeding of infants. However, as only a limited number of physicians can reach these laboratories with their prescriptions, the author makes an appeal for special instruction in this work.

Intracranial Hæmorrhage in the Newborn. By Dr. V. Reynolds Wilson.

The Causes and Treatment of Urgent and Serious Conditions in the Newborn. By Dr. Samuel Wolfe.—In a supposititious case the pulse is almost imperceptible and the skin and lips are ashen-gray or slightly dusky. When the child is handled it either does not cry at all or there is only a plaintive and pitiable sound. Under such circumstances the author has found the most gratifying results from the administration of atropia or atropoglycerin. Improvement in the complexion, the pulse, and the respiration can often be noted within an hour of the first dose. For such medication the author asks a careful trial in enabling a weak heart to gain power, and lessening the resistance in a collapsed lung, and incompletely expanded systemic capillaries.

Otitis Media in Children and its Treatment. By Dr. L. V. Würdemann.—This paper demonstrates the necessity for examination of the ear and care of aural inflammation in all cases of grave disease in children. The aracentesis knife should be used by the general practitioner as freely as the hypodermic needle, and he should be familiar with the reflecting mirror and aural speculum, at least for the purpose of diagnosis.

A Critical Review of the Literature of Mastoid Disease and its Complications. By Dr. Seymour Oppenheimer.

Diseases of the Ear in Relation to General Medicine. By Dr. Nathan G. Ward.—The author asserts that if dissections of the temporal bone are more frequently made at autopsies, and the findings compared with the symptoms before death, diseases of the ear that are now not recognized will be readily diagnosed and successfully treated.

Infantile Colic and Colic in Infants. By Dr. H. Loway.

The Diagnosis and Treatment of some Functional Forms of Defective Speech. By Dr. G. Hudson Makuen.

The Summer Cold: Swimming Pools as an Ætiologic Factor. By Dr. Lawrence F. Flick.

British Medical Journal, January 26, 1901.

Series of Original Communications on Tropical Diseases.

Summary of Researches on the Propagation of Malaria in British Central Africa. By C. W. Daniels, F. B.—The chief agent in the distribution of malaria in East and Central Africa is *Anopheles funestus* (Giles). The author allowed this mosquito to feed upon the blood of patients having malarial fever, and found that 47.5 per cent. became infected, zygotes being found in their stomachs. Several other species of *Anopheles* were found in Central Africa, but feeding experiments were negative. *A. claviger* apparently does not occur. The intermediate host of the malarial parasites appears to be man only. Examinations of the blood of cats, bats, birds, monkeys, etc., were uniformly negative. In certain localities sixty-eight per cent. of all children two years old and under have enlargement of the spleen. So that there is every reason to consider that quite a sufficient proportion of the natives have been, at one

time or other, hosts of the parasite to infect the small proportion of the numerous *Anopheles* requisite to produce the amount of "fever" present in the country. Preventive measures group themselves under four main heads:

1. *Diminution in the Numbers of Anopheles.*—Where it is practicable this will be the best method.

2. *Protection from Mosquitoes.*—This can be attained and is effective, as shown by the experiments of Sambon and Low. But *A. claviger* appears to be more strictly nocturnal in its habits than *A. funestus*, and therefore the method would not be of much service in Central Africa.

3. *The Extermination of the Malarial Parasite in its Intermediate Host, Man.*—This method, by the free use of quinine, would be expensive, and to be of value must be continued indefinitely.

4. *Isolation of European Settlements.*

No one method is, or can be, of general application to the exclusion of others. It is requisite that, regarding each species of *Anopheles*, direct proof should be obtained whether the human malarial parasites develop in them or not; in only a few is the proof at present conclusive, and it is being too hastily assumed that the whole genus is implicated.

Notes on the Life-history of "Anopheles Maculipennis" (Meigen). By Dr. L. W. Sambon.—The life-history of *A. maculipennis* has been chosen by the author as a good type to illustrate the biology of malaria-bearing mosquitoes, as in Europe it is certainly the chief propagator of malarial fevers. *A. claviger* (Fabricius) and *A. quadrimaculatus* (Say) are identical with *A. maculipennis*.

1. *Ovum.*—The egg of *A. maculipennis* is about 0.7 millimetre long by 0.16 millimetre broad, and is fusiform in shape. About one hundred eggs are laid, which float horizontally close to each other, forming irregular clusters. They usually hatch on the second or third day, the larva escaping by opening a lid at the extremity corresponding to its head.

2. *Larva.*—When full-grown the larva measures from seven to eight millimetres in length. It lies usually extended at the surface of the water with the penultimate segment just awash, so that the breathing stigmata may open freely at the surface. Its parallel attitude with the surface of the water is of great value in distinguishing it from the larva of *Culex*, which holds its body at an angle of sixty degrees with the surface.

3. *Pupa.*—The pupa is small as compared to the full-grown larva. Its head and thorax are closed within a transparent shell, through which can be traced the antennæ, legs, and wings of the perfect insect. The abdominal segments remain free and serve to propel the insect through the water. The pupa of *Culex* floats in a more perpendicular attitude than that of *Anopheles*. The duration of the pupal stage is about two days. The pupa case splits longitudinally through the middle of the back, and the imago extricates itself.

4. *Imago.*—In its perfect state, the insect may measure from seven to ten millimetres in length. The antennæ of the male are beautifully plumose, the hairs being very thickly set, by which the sex may be readily recognized. The palpi in both sexes are black and nearly as long as the proboscis; they at once distinguish the *Anopheles* from all species of *Culex*. The wings are brownish, with four dark spots. A very complete and thorough description of the blood-sucking apparatus and its mode of operation is given.

5. *Resting Attitude*.—*A. maculipennis* usually sits with its body at an angle of about thirty degrees. The position is midway between the perpendicular position of *A. pseudopictus* and the horizontal position of *Culex*. A valuable point is that the head, thorax, and abdomen of *Anopheles* form a straight line; the head and thorax of *Culex* form a decided angle with the abdomen.

6. *Breeding Grounds, etc.*—In Ostia the larvæ of this particular insect may be found in almost every water collection. The adult insects are found in great numbers in the houses and stables of the district.

The article is accompanied by a beautiful chromolithographic plate, showing most graphically the various stages of development of *A. maculipennis*.

Malaria and Mosquitoes in Zealand. By A. van der Scheer and J. B. van Berlekom.—The authors report the results of their studies of mosquitoes (*A. maculipennis*) infected with blood from persons suffering from malarial fever. On allowing healthy insects to suck malarial blood, it was found that infection took place only where the blood contained, not only the so-called febrigenous parasites, but also gametocytes, which are destined to undertake sexual functions in the mosquito's stomach and to form vermicules (zygotes). The first stage in the mosquito appeared two days after infection as a little egg-shaped body lying between the cells of the stomach wall. It was from nine to ten micromillimetres long by from seven to eight broad. These bodies increased in size and became pigmented; by the sixth day the pigment had again disappeared and the bodies had become spherical, having a diameter of from sixteen to eighteen micromillimetres. On the sixteenth day the capsules could be seen to contain thousands of thread-like bodies, which a few days later could be found in the salivary glands. The earliest period at which they were found in the glands was the twenty-first day. Sporozoites could not be detected in other organs than the salivary glands.

Whilst in tropical malarial diseases the gametocytes persist a long time after the paroxysms have ceased, in the tertian fever they disappear shortly after the last attack; never longer than one day after recovery. When *Anopheles* sucks blood two days later than the last paroxysm, infection never takes place. The presence of quinine in the blood seems to be no obstacle to the formation of vermicules in the stomach of the mosquito.

Preliminary Note on an Unclassified Type of West African Fever. By S. W. Thompstone, F. R. C. S., and R. A. Bennett, M. B., with an addendum by Dr. H. E. Annett.—The authors describe a form of fever observed by them on the West Coast of Africa, which is distinguished from malarial fever by the absence of malarial plasmodia and leucocytic pigmentation, and which they provisionally call "hyperpyrexial fever." It is ushered in by slight fever, followed by profuse perspiration and a fall in the temperature to 99° F. After an afebrile period of twenty-four hours, the temperature rises again, slowly at first and then rapidly, until it reaches 107° F. on the second day. For fourteen, or even thirty, days thereafter there is no tendency for it to fall. The skin acts very slightly and antipyretics are useless. The mind remains clear, and there is no disturbance of the urinary or digestive functions. The treatment may be summed up in one word—baths. Cold baths once a day will bring the temperature down to 99° F., and it may be kept down by cold packs at hourly intervals. If recovery is to take place, some change for the better is to be looked for at the end of the third week. But fully fifty per cent. of the cases die.

Observations on Fifteen Cases of Hæmoglobinuric Fever in British Central Africa. By H. Harsey, M. B.—Hæmoglobinuric fever may be defined as an acute febrile disorder, most probably of malarial origin, and characterized by the occurrence of an extensive and rapid hæmolysis. The duration of the hæmoglobinuria is usually about sixty hours, but it may be much shorter. The skin and conjunctivæ are distinctly jaundiced. In favorable cases the patient is usually well in a week. In fatal cases the vomiting continues, there is suppression of urine and the patient passes into an algid condition. If the urine is copious from the onset, the prognosis is good; if the quantity passed is suddenly diminished and the urine is of a dirty brown color, depositing much sediment, the prognosis is bad. Persistent severe vomiting is also a bad symptom. Treatment is mainly symptomatic. Quinine is entirely withheld throughout the illness.

Note on the Staining of Flagella. By J. B. Smith M. B.—The author recommends a modification of Pitfield's method, which he describes in detail.

A saturated solution of perchloride of mercury made by boiling is poured, while still hot, into a bottle containing an excess of crystals of ammonia-alum, and allowed to cool. To 10 cubic centimetres of this fluid 10 cubic centimetres of a fresh 10-per-cent. solution of tannic acid are added, and 5 cubic centimetres of carbol fuchsin. These are mixed and filtered. Cover-glasses are cleaned in a strong solution of hydrochloric acid wiped, and heated over a flame. The bacilli are placed upon the hot cover-glass, fixed, and the mordant solution dropped on. The specimen is then heated until steam rises. It is then well washed in distilled water and the stain added, and heated in the same way for three or four minutes. The stain is made by adding 1 cubic centimetre of a saturated alcoholic solution of gentian violet to 10 cubic centimetres of a saturated solution of ammonia-alum.

The Prophylactic and Curative Treatment of Plague. By A. Lustig and G. Galcotti.—The mortality among the patients treated with the serum introduced by the authors may be placed at about fifty-three per cent. while the general mortality for plague for the same period was about ninety-four per cent. They compare their results with those attained by the use of the sera of Yersin, Haffkine, Roux and others, and claim that their serum is the only one which has given satisfactory results in Bombay.

Dysentery in South Africa. By J. J. Day M. R. C. S.

Notes on the Lesions Produced by Oxyuris Vermicularis. By Dr. M. A. Ruffer.—At the *post-mortem* examination of an Egyptian who had died from chronic cirrhotic disease of the liver many small worms (*Oxyuris vermicularis*) were found in the contents of the large intestine. Many encysted calculi of varying sizes were found in the walls of the intestine, which consisted of an amorphous yellowish-brown substance, containing numberless typical eggs of *Oxyuris vermicularis*.

A Filaria Found in Sierra Leone? Filaria Volvulus (Leuckhart). By W. T. Prout, M. B.—The author describes a filaria which he found in a tumor on the buttock of a frontier policeman. On dissection, the cyst was found to contain only two worms, one male and one female. The male worm was about 3.025 centimetres long, white in color and somewhat flattened. The female worm was about 40.4 centimetres long, the body being striated from end to end. The author gives a table showing the characteristics of the various forms of

laris, and concludes that the one described by him probably corresponds to *Filaria volvulus* (Leuckhart).

Remarks on the Apparent Immunity of Asiatics from Enteric Fever. By Dr. F. W. Clark.—During the ten years, 1890-99, only fifty-one deaths of Chinese from typhoid fever in Hong Kong were registered as against sixty-five deaths among other than Chinese, although the Chinese form ninety-four per cent. of the total population. The author's theory to account for this is that the Chinese are so fully exposed to infection with the disease during the whole period of their existence that they almost always contract it during infancy or early childhood, when, if they recover, the disease will have been practically unnoticed, while, if they succumb, the death will be attributed to diarrhoea, convulsions, or some other symptom. Observations at the Government mortuary go far to confirm this view.

Revue de chirurgie, November 10, 1900.

Technics of Colostomy.—M. H. Hartmann describes his technique of performing inguinal colostomy for inoperable tumors of the rectum, by which he avoids the usual accidents of incontinence, cicatricial stenosis, and collapse of the intestine. The peculiarity of the operation consists in the careful separation of the muscular planes of the abdominal wall.

Exclusion of the Intestine. By M. Terrier and M. Bosset. (*Continued article.*)

Technics of Exploratory Craniotomy.—M. A. Codilla describes an apparatus of his own device for the osteoplastic resection of the skull. Rapidity, certainty, and a minimal scar, with maximal field of operation, are the chief virtues of the operation.

Resection of the Median Nerve in the Forearm.—M. Péraire and M. F. Mally describe an operation of this kind which was rendered necessary by a lipoma that had integrated the nerve at the site where it grew. The patient recovered functionally well.

Phelps's Operation for the Cure of Hernia.—Dr. M. Phelps describes the technique of his operation and for the closure of wounds of the abdomen and muscles by means of the use of a network of silver wire.

Nassilov's Operation of Œsophagotomy. By M. A. Llobet.

Cancer of the Large Intestine, except the Rectum. By M. R. de Bovis. (*Continued article.*)

Gynécologie, December 15, 1900.

Enucleation of Fibroids by the Vaginal Route.—M. A. Doléris reports four cases in which he enucleated uterine fibroids from below. Three of the patients suffered from a renewed growth of the tumors, and the fourth, although a young woman, never became pregnant. He does not favor the operation, since the hæmorrhage is not perfectly under control and septic infection is easier than when a hysterectomy is performed, and because recurrence is possible, since all the growths may not be removed. Hysterectomy is the operation of choice. Vaginal enucleation may be performed under very limited indications.

Subcutaneous Grafting of Ovaries.—M. P. Maucadre has made a number of experiments on dogs by grafting their own and other ovaries under the skin. He has performed the operation seven times in women. He says that the transplanted ovary will thrive if it is aseptic when it is grafted. The ovaries thus grafted multiply menstrual anomalies and relieve the ovarian insufficiency following unilateral or bilateral oöphorectomy. In the case of fibroids or cystic ovaries, if the

ovaries cannot be left in the abdomen, they may be grafted under the skin. The grafts can be made after either an abdominal or a vaginal operation. In the latter case, if one of the removed ovaries appears to be healthy, it may be subcutaneously transplanted if there are no adhesions or other evidences of previous infection. If after twenty-four hours there is a febrile movement, it had better be removed. The grafts may even be made after the menopause to secure for the patient the effects of the so-called internal secretion of the ovary.

Appendicular Inflammation Complicating Affections of the Uterus and Appendages.—M. Henri Delagénière writes of the pathology, symptoms, and treatment of appendicular inflammation, when complicating other pelvic diseases in women. He records twenty-six cases, four of acute, five of obliterating, five of calculous, ten of chronic, and two of cancerous, appendicular inflammation. Treatment is entirely surgical, the author making a median celiotomy.

Ovarian Cysts Complicating Pregnancy and Labor. By M. Bossi.

Total Abdominal Castration.—M. G. Nance says the abdominal is to be preferred to the vaginal route when the uterus and its appendages are to be removed, for the operation is easier since it provides greater space, temporary hæmostasis is not necessary, and one can go wide of the disease, rendering recurrence less likely. It is the true surgical procedure, he thinks, since one can see well what one is doing.

Archiv für pathologische Anatomie und Physiologie und für klinische Medicin, October 8, 1900.

Adenocarcinoma of the Liver with Ciliated Epithelium.—Dr. Alexis Sokoloff describes a case of this character with minute details of the histological findings. The presence of the cilia he does not absolutely account for, although he is inclined to ascribe it to a rapid proliferation of the cells of the tumor, with a gradual development of cilia. The metastases also presented ciliated epithelium.

Epibronchial Pulsating Diverticula. By Dr. Anton Brosch.

Theoretical and Experimental Studies on the Pathogenesis and Histogenesis of Malignant Tumors.—Dr. Anton Brosch lays down as the first "genetic" axiom: Normal tissues react to influences which overleap the tolerance of their cells, in a productive process; secondly, productive processes react to influences which overleap the tolerance of their cells, by a heightening of their reproductive rapidity and, if this potentialization is unlimited, by degeneration. For malignant degeneration, that is, for the genesis of malignant tumors, the pre-existence of embryonal germs is not essential, as they, as well as normal tissues, can degenerate malignantly if they enter a process of tissue production which is disturbed by injurious influences (irritants) in its course. The congenital tumors are not arguments in favor of the embryonal or of the "irritation" theory of the genesis of tumor formation.

Calcified Glomeruli of the Renal Cortex. By Dr. E. W. Baum.

Pathology of the Serous Surface Cells. By Dr. Max Borst.

Cartilage and Bone Formation in Heart Valves. By Dr. Paul Rosenstein.

Spontaneous Rupture of the Œsophagus. By Dr. Anton Brosch.—An elaborate experimental study.

Traumatism and Infection. By Professor Virchow.—An address delivered at the Thirteenth International

Congress. The mass of detail renders it impossible to abstract; but it will repay reading.

November 7, 1900.

Morphology of Milk. By Dr. Michael Cohn. (*Continued article.*)

Nucleoli.—Dr. R. A. Reddingino describes a new method of staining nucleoli in cells, spermatozoids, malignant growths, and normal tissues. The tissues are best cut in celloidin after hardening in alcohol. From absolute alcohol, the specimen is placed for from a few seconds to three minutes in Loeffler's methylene-blue, and is then washed in running water. It is next placed in a saturated alcoholic solution of picric acid until it is free from water. It is then placed in a watch-glass containing oil of origanum until it is transparent, and is mounted in Canada balsam. The pictures resulting from this process are very beautiful, the nucleoli standing out distinctly.

Immunity against Malaria.—Dr. Max Glogner, who accompanied the German malaria expedition to Sumatra and Java, concludes from his studies that an attack of malarial disease does not give immunity, but renders the individual even more disposed to the disease.

Relations of Cataract to Nasal Disease. By Dr. C. Ziem.

Sarcoma of the Oesophagus.—Dr. Hugo Starck says that this is a very rare disease, is infrequently diagnosed even when it exists, and is rapidly fatal, death usually ensuing in six months. Pain and dysphagia are prominent symptoms, but may be absent. When pain is present, it is intense and of a stabbing character, and is more intense when the stomach is empty, therein differing from the pain of carcinoma.

Case of Leucæmia Complicated with Miliary Tuberculosis.—Dr. Jünger reports a case of this kind. The blood count at various times showed an increase in leucocytes of from 40,000 to 120,000, and a change in the relation of white to red of from 1 to 95 to 1 to 25.

Pathogenesis of Inflammation, Hæmorrhage, and Multiple Fat Necrosis of the Pancreas.—Dr. Max Leonhardt reports such a case in which the tissues of the pancreas were almost entirely replaced by fat. Evidences of previous inflammation, such as cellular infection, hæmorrhage, and increased connective tissue, were present. In the pancreas and its neighborhood were multiple foci of fat necrosis. No normal pancreas tissue was found. Staphylococci and streptococci were found, which came from a duodenal ulcer; in other words, a septic infection of the pancreas had taken place.

Deformity of the Skull. By Dr. Martin B. Schmidt.

Gazzetta degli Ospedali e delle Cliniche, December 9, 1900.

Hyperleucocytosis and the Bactericidal Power of the Blood in Animals Deprived of the Thymus Gland. By Dr. Andrea Cosentino.—As the result of a series of experiments upon animals in which he had performed thymectomy, the author concludes that the removal of the thymus gland is followed by a well-marked hyperleucocytosis, and that the increase of the bactericidal power of the blood takes place in proportion to this leucocytosis. The explanation given of these phenomena is as follows: The thymus gland neutralizes a part of the toxins introduced into or developed in the body. When the thymus is removed, it is natural that the organism should seek to defend itself against the toxins

in some other way—in other words, by hyperleucocytosis. The presence of toxic substances in the blood of these animals after the thymus gland has been removed, stimulates the blood-forming organs to activity beyond the normal, and thus the increase of white cells takes place. The fact that the hyperleucocytosis is the more marked the younger the animal, also supports this theory; for the thymus gland is more active in young animals than in adult organisms.

The Blood of Cancerous Subjects. By Dr. Dario Maragliano.—The author has studied the bacteriologic features of the blood of cancerous subjects, and has reviewed the work of other observers in this field. He has examined, and has prepared cultures from, the blood of thirty-three persons affected with malignant growths. In the majority of cases the blood was taken from the cephalic vein. After a thorough disinfection of the skin, a cannula connected with a glass tube of about twenty cubic centimetres capacity was introduced into the vein. The first portion of blood that flowed into the tube was rejected, and the remainder was added to various culture media. The author has experimented with a great variety of media and with a variety of temperatures of incubation. In addition, he has examined the freshly drawn blood with the aid of different stains. He sums up his results as follows: In no case has the cultivation of blood specimens or of material obtained from the tumors given rise to the development of blastomycetes or of micro-organisms analogous to those described by Bra and by Chevalier. Many of the patients under investigation were in advanced stages of malignant disease, and there is no doubt that they were affected with carcinoma; for in the majority of cases the pathological report had confirmed the clinical diagnosis. The author cannot explain the difference between his own results and those of M. Bra and M. Chevalier, as the conditions surrounding the investigations of the latter observers were identical with those prevailing in his own case.

A Case of Resection of the Posterior Roots for Intractable Sciatica. By Dr. Davide Giordano.—The patient was a man, aged twenty-six years, who had suffered for a long time with severe attacks of sciatica. All forms of palliative treatment had proved ineffectual, and the author decided to attempt intradural resection of the roots of the sciatic nerve in a manner analogous to that which has already been practised in connection with the brachial plexus. The sensory roots of the nerve were exposed by making an osteoplastic resection of the posterior arches of the eleventh and twelfth dorsal and the first lumbar vertebrae. The dura was opened and the cerebrospinal fluid escaped in considerable quantities. The lumbar enlargement was found to be normal and the sensory roots were cut with a pair of scissors, each having been seized and elevated in turn with forceps. The wound in the dura was closed with catgut and the osteoligamentous flap was replaced, a strip of gauze having been introduced for drainage at the side of the wound. The soft parts and the skin were then sutured in layers. After the operation the patient was able to move his limb perfectly well, but sensation was practically abolished. On the second day a neuralgia of the right internal saphenous nerve appeared, and had to be treated with injections of cocaine. Evidently the author omitted to cut one of the sensory roots through its entire diameter. The pain, however, disappeared after a time. The patient rose from his bed without any pain on the twentieth day, but was not perfectly satisfied because the affected limb "seemed dead." Sensory com

munication was, however, gradually re-established, and in a few months the patient resumed his occupation, free from pain and discomfort.

A Contribution to the Methods of Fixation in Fractures of the Lower Jaw. By Dr. Giuseppe Piersantelli.—The method here described is an invention of Signor Bertoli, a dentist in Bologna. The author reports a case of compound comminuted fracture of the lower jaw in which he tried this method with such success that he was encouraged to publish the procedure. The apparatus devised by Bertoli should not be applied until a day after the injury, in order to give an opportunity for thorough washing and disinfection of the injured parts. It can be used in both simple and compound fractures of the lower jaw, and prevents the formation of a deforming callus or malposition of the fragments. It may be applied and worn without interfering with the motion of the jaw or with mastication. The patients tolerate the apparatus well; the more so because by means of a screw they can regulate the amount of pressure exercised upon the bone. The apparatus is illustrated by a number of cuts accompanying the article. It consists of a cap of silk or linen fitting the top of the patient's head and provided with chin straps with buckles, passing in front of the ears and fastening under the jaw. The chin straps are also provided with rubber elastic bands which tend to hold the cap taut when applied. The straps passing from the cap are attached to a nickel-plated metallic chin piece or shield, which is adjusted in front of the lower jaw, is padded so as to adapt itself perfectly to the chin, and is provided with two elastic straps passing horizontally backward and clasping in the back to the neck, thus preventing a forward displacement of the chin piece. To the front part of the chin piece is soldered a horizontal metallic bar, which can be lengthened or shortened at will by loosening a screw which holds an extension-piece entering into the hollow portion of this bar. By means of another screw a vertical bar is attached to the first, passes upward and terminates in a curved arm passing over the teeth and provided with a small screw. A dental splint of the regular horseshoe pattern constitutes the last part of the apparatus. This splint is made of hard rubber and its under surface is re-enforced with a plate of perforated metal. Into the hollow of this splint Stent's paste is poured, after having been melted to a sufficient degree, and the splint is applied over the teeth, care being taken to see that the line of teeth is regular. The paste must not be too hot, for otherwise it may injure the soft tissues; nor too cold, for in that case it will not adapt itself perfectly to the line of teeth. The little screw is next screwed into the plate which has been affixed to the top of the middle portion of the hard-rubber splint. The other screws (of the vertical bar and horizontal bar) are then adjusted to regulate the compression exercised from below upward in front of the chin piece, pressing the teeth with their splint toward the point of the chin. The results obtained by the author in this case leave no doubt as to the utility of Bertoli's apparatus.

Epiploitis Following a Radical Operation for Strangulated Epiplocele. Laparotomy. Recovery. By Dr. Latis.

Twin Pregnancy with a Trilobate Placenta Intermedia. By Dr. Donato De Francesco.

A Contribution to the Use of Suggestive Therapeutics in Hysteria. By Dr. C. Rinoldi.—The author reports three cases of hysteria in which he used the following method with marked success: He gave the pa-

tients some pills of methylene-blue, and with "a certain air of mystery" told them that this was a rare and new remedy of extraordinary efficacy, and that if their urine should become colored blue they would know that the poisons which caused their disease had been eliminated from the body. This method of treatment was introduced by Pittres a few years ago. The present author thinks very highly of it, and reports complete success in the three cases in which he has employed it.

Rassegna d'Ostetricia e Ginecologia, December, 1900.

A Contribution to the Treatment of Genital Prolapse by Chiarleoni's Method. By Dr. G. Prunas-Tola.—Professor Chiarleoni rejects hysterectomy in the operative treatment of genital prolapse, except in cases in which there is a new growth in the prolapsed uterus. He has obtained good results in fifty cases operated on by his method, and eighteen additional cases of prolapse were reported by Cucca and Unargo as cured after operation according to Chiarleoni's procedure. The author reports two cases in which Chiarleoni's operation was performed with marked success. During an experience of five years in gynecological hospital practice the author has had ample opportunities for observing the results obtained by the radical operations for uterine prolapse, and has been forced to conclude that hysterectomy should not be performed in these cases, but that plastic vaginal operations are sufficient. That of Hegar seems to him the most suitable operation for the purpose of supporting the fallen womb. In the two cases reported here, however, he employed Chiarleoni's method. According to the opinion of Mangiagalli, who insists on hysterectomy, the author should have removed the uterus in both cases, as, in one, there was an enormously hypertrophied womb, and in the other, a bilateral laceration of the cervix. In the first case the operation was followed, not only by a perfect replacement of the uterus, but by a return of regular menstruation. In the second case the patient passed successfully through a normal labor after the operation without any return of the prolapse.

The Principal Alterations in the Organs of the Macerated Fœtus. By Dr. A. Cosentino. (*Concluded.*)

Second Statistical Report of the Annunziata Maternity of Naples. By Dr. S. Buongiorno. (*Concluded.*)

Vratch, December 16 (O. S. 28), 1900.

On the Physiology of the Cœliac Plexus. By Dr. L. V. Popelsky.—The difficulties surrounding the investigation of the functions of the cœliac plexus will be apparent when we remember the deep situation of this part of the nervous system, and when we consider the fact that it is almost impossible to reach it in the living animal without infecting the peritoneal cavity. In the investigations conducted by the author, special attention was therefore paid to asepsis and antisepsis in operating upon the animals under observation. The author carefully removed the whole mass of nervous tissue between the cœliac and superior mesenteric arteries, cut away all nerve filaments from both these arteries and from their branches, and severed the nervous connections of the cœliac ganglia with the suprarenals and with the inferior mesenteric vein. The operation was performed on seventeen dogs, of which five were still living after a period varying from three months and a half to seven months, while the others perished in a space of time varying from twenty-four hours to twenty-five days.

The results of the operation were diarrhœa and intestinal hæmorrhages, especially during the first two weeks after the operation. After a while the fæces became more concentrated, and assumed a whitish color. In some dogs the evacuations were liquid with whitish masses floating about, or the fæces assumed a jelly-like appearance, and contained masses of epithelial cells and blood corpuscles. After a month or two the fæces again became normal in appearance, but from time to time there were evacuations of semi-fluid, steel-gray or whitish masses. The evacuations were abundant and had a very foul odor. In spite of all these disturbances on the part of the intestines, the dogs continued to eat well and were to all intents normal in every respect. In spite of the good appetite, however, some of the dogs perished from exhaustion as a result of the diarrhœa, but the autopsies showed no traces of peritonitis—nothing more than a severe anæmia. At the autopsies, the author found quantities of bloody fluid in the stomach and intestines. The mucous membrane of the stomach, as well as that of the upper and lower portions of the small intestine and of the upper part of the large gut, showed the presence of extravasations of blood and very severe hyperæmia. In three dogs there were many large ulcers in the duodenum, the stomach, and in the upper portion of the small intestine. The source of the hæmorrhages, which occurred several weeks after the operation, was therefore to be sought in these ulcers, and the dark or steel-gray color of the fæces was to be attributed to the admixture of partly digested blood from the upper parts of the tract. The Peyer's patches were found to be atrophied. (*To be continued.*)

Concerning the Significance of Mental Depression in the Origin of Disease. By Dr. A. K. Federolf.—The author has asked himself the question: What is the nature of that condition of diminished resistance which is said to render the organism receptive for disease? It is a well-known fact that mental depression produces a diminution of sensibility on the part of the sensory organs and a diminution of the reflexes—in other words, a depression of the activity of the entire organism. The products of metabolism, which under ordinary conditions are eliminated or destroyed in the body, are retained and absorbed in the presence of mental depression. The author believes that in such cases there is a narcotization of all the elements of the body, including the nerve-cells. The products of metabolism, collecting in the blood, act as narcotics upon the protoplasm of the cells, render the sensitiveness of the phagocytes less acute, and thus interfere with the important defensive functions of these elements. In addition, the second physiological function of the phagocytes—the elimination of the alexines which act as antidotes to the toxins—is also diminished by the products which thus accumulate. Furthermore, in mental depression there is always anorexia and a lowering of the nutrition of the cells.

Comparative Estimation of Various Methods of Studying Syphilis in Villages; House-to-house Examinations of the Population; their Significance and the Methods of Organizing them. By Dr. A. J. Efimoff.

A Rare Case of Placenta Succenturiata. By Dr. V. N. Orloff.—The placenta in this case consisted of one central portion and four placenta succenturiata. The funis was attached to the central mass—not to the middle of it, but between the central mass and the additional portions. The umbilical vessels were continuous from the point of insertion to the appendices. The author be-

lieves that the cause of the development of the placenta succenturiata in this case was the existence of endometritis, which prevented the development of placental tissue in the regular way.

Letters to the Editor.

OPINIONS ON THE BELL BILL.

63 EAST SEVENTY-NINTH STREET,
NEW YORK, February 2, 1901.

To the Editor of the New York Medical Journal:

SIR: The profession must know, of course, that a bill has been introduced into the legislature of this State, the purpose of which is to enable those who are empowered to do so to enforce the medical laws. As at present interpreted, these laws can only be enforced against illegal practitioners who give medicines. If a person desires to evade these laws all it is necessary to do is to adopt some peculiar title, such as Christian Scientist, osteopath, hydropath, faith-curist, or even no name, and refuse to give medicines or drugs; although such a person may treat disease, there has been, as yet, no lawyer who will advise action against such illegal practitioners. The law as at present enforced is an incentive to uneducated people to adopt some of these peculiar names or methods, and they can practise medicine with impunity and without molestation.

The bill under consideration was objected to in the beginning by manufacturers of proprietary articles, opticians, and others, who maintained that its enactment would prevent a person from recommending a dose of pepsin or some equally simple remedy to a friend, and would interfere with the sale of patented articles, and in this way interfere with newspapers advertising such articles. The framers of this bill had no such intention in drawing the measure, and agreed to alter its phraseology, which has been done. As it reads now, the bill declares that any person shall be regarded as practising medicine who shall give treatment to any other person, by any method whatsoever, for the relief or cure of disease, excepting in an emergency. There can be no valid reason for objections to this bill on the part of patent medicine manufacturers, wholesale or retail druggists, truss or instrument makers, or any other person who does not make a business of treating disease. Retail druggists have no right now to treat disease, except in an emergency, and this bill will not alter their position or curtail their rights in any way. The legitimate business of an optician will not be interfered with in any way. This bill is designed to give an increased protection to the public, which is the only reason for the existence of any medical laws. The effect of the bill will be to compel Christian Scientists, osteopaths, and others who treat disease to comply with the medical laws, after which they can continue their peculiar methods if any one can be found to endorse them, or if they continue to believe in these methods themselves. There is no desire to interfere with free thought or religious liberty. There is no desire to prevent any person from practising any method his or her intelligence tells him or her is the best method. We only desire that every person who treats disease shall demonstrate to the State board of medical examiners his or her ability to tell whether a disease exists and to distinguish the disease which may exist, and then the matter of treatment must be left to individual judgment.

The battle is on, and will be won by those who believe in protecting the community, if all who so believe will write to the Hon. Nelson H. Henry, chairman of the assembly committee on public health, giving their names and addresses and urging the enactment of the bill. Will you not urge your readers to do this?

FRANK VAN FLEET, M. D.,

Chairman of the Committee on Legislation of the Medical Society of the State of New York; Chairman of the Board of Censors of the Medical Society of the County of New York.

119 EAST ONE HUNDRED AND TWENTY-EIGHTH STREET,
NEW YORK, February 3, 1901.

To the Editor of the *New York Medical Journal*:

SIR: The noble dictum *Audiat et altera pars*—let the other side also be heard—though it originated two thousand years ago, has never found general or wide acceptance until the latter part of the nineteenth century. It is only now that a large majority of people are ready to lend a willing ear to every claim, no matter how absurd; it is only now that we are ready to examine with an open mind different theories and hypotheses regardless of the obscurity of their paternity; and at no time in the history of the human race were people so careful not to condemn any theory, doctrine, or system without giving it an impartial, unbiased hearing. And, though in our desire to be fair and judicial some of us are apt to go rather too far, I hold that this, so to speak, expectant attitude is preferable to the intolerance and dogmatism of olden times.

Though Christian Science came with the ear-marks of fraud on the very face of it, I decided not to condemn it until I had heard all its advocates had to say in its favor. For the past three years I have taken special pains to hear both sides of the question, and this careful and impartial study has led me to the conclusion that this so-called science is an amalgamation of fraud and imbecility—fraud so contemptible and imbecility so shallow that it is questionable whether the world has ever before seen anything like it offered up as a “system.” As to the followers of this system, while I do not like to classify them *all* as either fools or knaves, or a mixture of both, I can honestly say this: I have not met one Christian Scientist capable of fair, rational, and consistent reasoning. The word *logic* seems to have become completely eliminated from the vocabulary of the followers of that creed.

I am not a paternalist, and do not believe in hedging the individual all around with laws and statutes, but the line must be drawn somewhere, and I believe that the State has the right, nay, it is its duty, to protect the health and the lives of its citizens, particularly of the young and innocent, who have no voice in the matter. The attempt of the Christian Scientists to trifle with the lives of the people should be strenuously opposed. Their pretention that they give no medicines, consequently they do not practise medicine, is both flimsy and dishonest, because *negative* treatment is just as much treatment as *positive* treatment is. If a man's heart is failing, and we fail to give him anything to sustain it, we treat him, or rather we mistreat him, just as much as if we gave him the wrong drug. Anybody who professes to treat disease—be the means material or spiritual—is practising medicine, and it would be a sad state of affairs, indeed, if all any quack or charlatan would have to do, in order to avoid the restrictions of medical laws, would be to allege that he was not a drug-giving physi-

cian. A law like the one contemplated by the Bell bill is, therefore, a necessity, and the said bill should be supported by physicians generally.

But the language of the Bell bill is too sweeping, and in my opinion the bill needs some amendments.

The feature which affects the pharmacists so that they cannot recommend a headache powder or a quinine pill is especially objectionable—objectionable and short-sighted—because it will have an effect opposite to the one expected. If the framers and supporters of the bill think that forbidding the druggists to sell little things for slight ailments—a privilege they have enjoyed from time immemorial—will have the effect of throwing more patients into our offices, they are mistaken. You cannot compel a man to pay one or two dollars for every little ache and pain; and it would be rather funny if people had to consult a doctor before they could get a corn cure, or toothache drops, or a hair tonic. So the only effect this feature would have would be to drive people still further to self-medication, to newspaper medicine, and to the use of patent nostrums. And then what talk there would be about medical trusts and medical monopoly! I know whereof I speak.

WILLIAM J. ROBINSON, Ph. G., M. D.

Proceedings of Societies.

AMERICAN LARYNGOLOGICAL ASSOCIATION.

Twenty-second Annual Congress, Held (in Conjunction with the Congress of American Physicians and Surgeons) in Washington, on Tuesday, Wednesday, and Thursday, May 1, 2, and 3, 1900.

The President, Dr. SAMUEL JOHNSTON, of Baltimore, in the Chair.

(Continued from page 172.)

Bullous Enlargement of the Middle Turbinate Bone (“Concha Bullosa”).—Dr. J. PAYSON CLARK, of Boston, read a paper with this title. (See Vol. lxxii, page 670.)

Dr. JONATHAN WRIGHT, of Brooklyn: This paper is certainly a very clear exposition of the subject, but there is one criticism to make with reference to the ætiology, and that is, that the enlargement of the middle turbinate is developed from foetal life without any inflammatory action connected with it. I do not know that Dr. Clark meant to state that, but in some of the remarks in the paper I should judge that was the tenor of it. I doubt very much whether this is true. I have seen two or three cases in my clinical work, and have examined seven or eight others microscopically, and I have come to the conclusion that there is a pre-existing cavity in the end of the turbinate bone to start with, and the subsequent development is in all probability due to an osteitis. Without going into the pathology, which the author has stated clearly, there is one point that he did not touch upon, and that is with reference to the peculiar location of the osteoblasts and the osteoclasts. They are respectively the cells which form bone and which absorb bone, and the histologist, as you know, says they are interchangeable; that is, the osteoblasts can be changed into osteoclasts. They are of a little different shape, but by careful study one can recognize them. If we study them carefully, we nearly always find that the osteoblasts are larger, rounder, and fuller cells. The osteoblasts are usually situated upon the convex surface

of the cavity. There is a bulbous cavity like this (indicating); we find the osteoblasts arranged around the outside of the bone. The cells on the inside of the concavity are of different shape and correspond closely to what are called osteoclasts. It occurs to me that there is probably an osteitis set up in the walls of the pre-existing cavities, and by this unequal growth the osteoblasts form bone upon the outside and the osteoclasts absorb bone on the inside; beneath the lining of the embryonal mucous membrane there is this enlargement in these cavities going on.

While I am not perfectly sure of my observations in these cases, because it is hard to distinguish between osteoclasts and osteoblasts, it seems to me a plausible explanation of the formation of these cavities. I do not believe that these cases exist in children, or until a considerable time after puberty. If they did exist, we should see them. They would give rise to symptoms, so that at least a few cases would be seen.

As I remember the literature of the subject, I think Dr. Clark has overlooked the report of a few cases. I had a number of cases some few years ago, and when I looked up the literature at that time, there were eighteen or twenty cases on record. It seems to me that there are more cases than that on record now. It is certainly very interesting to know how this peculiar condition arises. It seems to me that it requires a good deal of imagination on the part of MacDonalld to advance such a theory as he has. The question of sex in these cases is interesting. Why they should appear in women almost exclusively, or why they should appear in women only after the age of puberty, is certainly a very remarkable thing. We have notable examples of sex in nasal pathology, and atrophic rhinitis, of which we speak, is one. This is another. This feature is entirely inexplicable; yet there must be some cause for it.

Dr. CLARK: I have only one or two points to consider in reference to what Dr. Wright has said. I am not a histologist, and I have to take the word of others as regards the presence of inflammatory action; but the gentleman who examined the specimens for me distinctly stated in his report that there were no evidences whatever of inflammatory action. I must say that the growth of such large bodies as these would seem to require some sort of chronic inflammatory process, and what Dr. Wright has said is very interesting and pertinent to the matter. As regards the number of accounts of cases which I have found, I found many more, but I felt compelled to exclude them because they were incomplete, or did not seem to me to answer the description of the cases that I have detailed.

Cyst of the Vocal Cord.—Dr. CLARK presented this case also.

Fibroma of the Larynx.—Dr. A. B. THRASHER, of Cincinnati, read a paper thus entitled. (See Vol. lxxii, page 588.)

Dr. W. K. SIMPSON, of New York: Did the microscopical examination of the tissue that you removed at the time of operation agree with the first microscopical examination, so that the case could be put under the head of fibroma?

Dr. THRASHER: The examinations were practically similar in character.

Were these Unusual Cases of Partial Paralysis of the Vocal Bands Caused by Over-use of the Telephone?—This was the title of a paper by Dr. CLARENCE C. RICE, of New York. (See Vol. lxxii, page 452.)

Dr. SAMUEL W. LANGMAID, of Boston: We are greatly indebted to Dr. Rice for calling our attention to this subject. I have never been able to ascribe such trouble to the use of the telephone. I do not recall any such case whatever, and it is possible that this cause has in many instances been overlooked. I think his clear description of the latent condition of the larynx is worth calling attention to.

Dr. T. AMORY DE BLOIS, of Boston: It might be pertinent in this connection, as I did not hear all of the paper, to speak of a case which I saw last winter at the hospital. A man slipped down from a ladder, striking on the bottom rung on the back of the head. As a result, the muscles of the larynx were very much compressed. He had marked hoarseness and inability to approximate the vocal cords for several weeks. This condition passed off with rest. I attributed this to sudden muscular strain.

Dr. WILLIAM E. CASSELBERRY, of Chicago: I have no recollection of any cases in which the telephone itself could be assigned as the cause of paralysis of the vocal cords; but I recollect distinctly a case in which similar conditions produced paresis of the vocal cords, which subsided when the conditions were modified. The case was that of a clergyman who spoke with frequency, and had the habit when preaching of getting into a high state of nervous excitement, so much so that his voice would mount into a high falsetto key, which was evidently a great strain upon the vocal organs and a disagreeable feature to his audience. After some years of this method of preaching he appeared for treatment with marked paresis of the vocal cords, such as was described in the second case reported by the author. His voice had become so weak that he could preach only with great difficulty. There was paresis of both vocal cords, but it was more marked upon the right than the left side. I explained to him the nature of his difficulty, pointed out its serious character, and urged him to modify his method of preaching. First, I prescribed absolute rest for a time, then a modification in his method of preaching, and urged him to avoid the nervous excitement into which he threw himself while preaching, and to maintain a low, composed tone of voice. This he has since practised with persistence and success as regards both the pleasant character of his speaking and the alleviation of his laryngeal paresis.

Dr. JAMES E. NEWCOMB, of New York: I have had one or two cases of telephone girls who came to me with slight ear troubles. They get along as well as they think they should, considering the nature of their business. You will remember that the transmitter is hung directly before them, so that they sit back in a chair with perfect ease, and in talking assume almost an ideal position for the muscles of the neck, so that the expenditure of force is no greater than is absolutely necessary. There, too, we have all noticed that, in conversing with the central office, the speakers say no more than is absolutely necessary.

A Case of Pin in the Larynx.—Dr. A. W. ROALDES, of New Orleans, reported this case. (See Vol. lxxii, page 589.)

A Peculiar Case of Migratory Foreign Body.—The case was presented by Dr. D. BRADEN KYLE, of Philadelphia. (See page 89.)

Dr. LANGMAID: Dr. Kyle has referred to a case; the specimen I have here in a bottle. The specimen was extracted whole, but became broken. My case was sim-

ilar in many respects to the one described by Dr. Kyle. I described what I thought was a granulation tumor on the walls of the pharynx, extending over the arytenoids and preventing a view of the glottis. This pin (specimen) was in the larynx, having been sucked in three months before I saw the patient. Its length is of interest because it is one of the old-fashioned brass pins, such as we rarely see nowadays. The patient was a cashier in a factory and had used this pin to fasten money together. Dr. Knight happened to be in my office when the patient came in. By means of escharotics I picked off the tumor, and after a time I could see the larynx, but the left side was swollen. The arytenoid and the ventricular band were swollen so that I could not see the cord at all. The woman was much emaciated, having lost eight or ten pounds, and was afraid of tuberculosis. At the end of three months more she came back to me with a black spot on the ventricular band. In another week I was able to see the point of the pin, and then made a diagnosis of a foreign body. With reference to the extraction of these foreign bodies, Dr. Kyle said that one should use strong instruments and be careful to extract the foreign body at the first attempt. In my case, the first time I put the forceps on it was not strong enough. It yielded and I was not able to extract the body. I then applied a more powerful forceps and succeeded in extracting the pin. This case occurred in my practice in 1889, and a full account of it will be found in our *Transactions*. It was the second case I had had. I simply referred to the first case because of the remarks of Dr. de Roaldes as to the exact situation of these foreign bodies. The first case was that of a little girl who had accidentally put into her mouth a pin which had slipped down into the throat. I was called by the family physician and found the pin in the side of the larynx. What Dr. de Roaldes has said in regard to the manner in which the pin gets into the larynx may be true in many cases, but it would seem that this method would not have been applicable to my own case. Here, the pharynx was perforated by the head of the pin and, in the act of swallowing, it was gradually carried farther into the tissues, this process being continued until it was fairly embedded in the cellular tissue behind the back wall of the pharynx. By the further act of swallowing, rotation took place with the head of the pin down.

Dr. THRASHER: I desire to emphasize the advantages which are to be derived from one of the manipulations referred to by Dr. de Roaldes in the removal of these foreign bodies, namely, the introduction of the finger into the vestibule of the larynx for the purpose of assisting in the removal of the object. I had occasion a number of years ago to remove a pin that had been embedded in the larynx for a number of years. The patient was a child. The child was very refractory, but under the influence of chloroform I could with perfect ease touch the foreign body with the tip of my finger, and with the aid of a forceps its removal was easily accomplished. Fortunately, in this case the head of the pin had fallen beneath the epiglottis, the point having transfixed the posterior portion of the right aryteno-epiglottic fold. Foreign bodies in the ventricle of the larynx or above the vocal cords can be touched by the point of the index finger and valuable assistance derived in this way. I am very glad to know that some one else has taken advantage of this little manipulation, and it might have been used as a diagnostic measure in the case I had. No one had been able to see the pin in

my case or to determine that a pin was there, except possibly a very skilled laryngologist (?) in a neighboring city, who said that he had discovered it in the right apex of the lung with the aid of the microscope! The presence of prolonged coughing and the fact that the case was rapidly passing into what was considered consumption induced the parents finally to bring the child to me.

Dr. J. E. BOYLAN, of Cincinnati, Ohio: The surprising difficulty at times experienced in extracting pins from the larynx, referred to by the author, recalls to my mind an experience of my own. In my case the pin was not within the larynx, but deeply embedded in the fold between the base of the tongue and the epiglottis, and very effectually hidden, so that it could only be seen with the laryngoscope when the tongue was well drawn out. The symptoms were referable to the larynx and for this reason it escaped observation for quite a while during inspection. About one third of the point end of the pin had penetrated the lateral glosso-epiglottidean fold, while the head was pressed deep into the median fold—so that about a third of the pin was visible, lying transversely in the recess at the base of the tongue on the right side. The only suitably curved forceps that I happened to have at hand was a large and rather clumsy œsophageal one, and yet even that slipped, to my surprise, when traction was made in an effort to dislodge the pin. At the next attempt the point of the pin was pushed still farther into the issue by a lateral bolt-like movement, which disengaged the head from the median fold, after which the extraction was very simple.

Dr. F. PEYER PORCHER, of Charleston, S. C.: I wish to lay stress on the necessity of having a good forceps for the extraction of these foreign bodies. It has been my fortune to remove two pins from the larynx within the last few months, and I find that Schroetter's tube forceps, as made by Hajek, of Vienna, is most excellent for that purpose. Most of us who have studied under Schroetter will remember old Frau Daly, who used to permit the students to insert a china bead into her larynx and extract it for a small pecuniary consideration. It was here that I learned the use of this forceps. Of course, thorough cocainization of the larynx is necessary to control the spasm, but in very young subjects the removal of these foreign bodies would at best be difficult to accomplish. With your permission, I will take this opportunity to show a fish-bone which I took out of a patient's throat. There is nothing remarkable about this bone except the vicious character of it. As will be seen, it consists of two spines connected by a thin lamella of bone in the shape of a triangle. The apex of the triangle was sucked down into the throat and the two spines were buried in the laryngeal mucous membrane, so that the sharp edge of the lamella was the only thing visible in the mirror. I examined the man for half an hour before I could detect anything at all, and then I saw what looked like a crack in the glass, but the crack moved, so that I knew it must be a foreign body. The alligator grip of the forceps readily took hold of it, and it was easily extracted.

Dr. T. M. MURRAY, of Washington, D. C.: I have seen two cases of pins in the larynx, although one of them was really not in the larynx when first seen, but was sticking in the lower part of the pharynx with the head down. I found some difficulty in removing it. The forceps, though strong, slipped, dropping the pin into the larynx. Its removal was successfully accomplished in the second effort.

Dr. SIMPSON: Our experience with foreign bodies or pins in the larynx is sometimes discouraging, and it is well for us at the outset to be careful not to let the forceps slip. We must be sure of the location of the foreign body, having the larynx thoroughly cocaineized, and we should be able, if possible, to extract it the first time. A very valuable little point is to try the forceps one is about to use upon a pin or needle before introducing it into the larynx, giving it all the pulling one possibly can, to see whether it will slip or not. I believe in these cases we should use a sharp-end forceps. The ordinary rough forceps will slip. It is surprising what sharp forceps can be used on a pin or needle without breaking it. I prefer the use of Schroeder's tube-forceps.

Dr. CASSELBERRY: In reference to the use of the x-ray and the burn that was produced, I should like to ask Dr. Kyle as to the time of exposure, and whether these burns may possibly be avoided by shorter exposures.

Dr. DE ROALDES: I should like to say, first, that it seems to be pretty well admitted that the removal of pins from the larynx, especially if embedded, is not so easy as it may seem. The great trouble is that we do not always know the exact position of the pin, and particularly the relative position of the point to the head. In answer to Dr. Langmaid, I should say that in the majority of cases reported the head of the pin was lower than the point, seeming to indicate that generally the pin slips down head foremost, as a result of its original position between the teeth or lips with the head in the mouth and the point externally, for fear of pricking the tissues, or, again, as a result of an inversion of the pin in its descent by an adaptation of its centre of gravity. On the contrary, if the pin is inhaled with its point foremost, the latter is very apt to become stuck in the tissues, with the head upward. Furthermore, we must remember that the position at first occupied by the pin in the larynx may be materially modified by the spasmodic contraction of the parts. In one case the observer mentions that the pin was seen at first with its head resting against the posterior surface of the epiglottis and the point pricking slightly the interarytænoid tissues. Nothing was done for a few hours, but subsequently the patient was examined again, and it was found that the head had been pushed backward by the epiglottis, and that the pin had transfixed the soft parts. With reference to the use of cocaine preparatory to the extraction of these foreign bodies, I deem it the anæsthetic *par excellence* in adults and in docile patients, in whom the parts are not too irritated or swollen. This anæsthetic, however, will be found more than once disappointing in children, especially in cases of long standing, in which the pin is embedded in inflamed or swollen tissues and there exist constant pricking sensations in the throat, with abundant secretions. Under these conditions, cocaineization is a real operative act, which, as a result of fear, or of actual pain, is strongly resisted by the little patient. In such cases general anæsthesia is preferable, particularly if, as is sometimes indicated, one has to make use of the index finger of the left hand to steady the larynx while the right hand holds the pin in a firm grasp of the forceps.

Dr. KYLE: In reply to the question of Dr. Casselberry as to the time of exposure in this case, I will say that Dr. Prince had charge of the x-ray apparatus during this exposure in which a burn was produced, and I

do not recall the exact time of the exposure. I believe that it is not so much the long exposure that produces a burn as it is the peculiar idiosyncrasy of the individual. Some patients have been exposed almost an hour, with no burns whatever. I know that the exposure in this particular case was much shorter than in some of the others, so that I do not believe the time of exposure has much to do with it.

(To be continued.)

Book Notices.

A Text-book of Histology, including Microscopic Technique. By A. A. BOHM, M. D., and M. VON DAVIDOFF, M. D., of the Anatomical Institute in Munich. Edited with Extensive Additions to both Text and Illustrations by G. CARL HUBER, M. D., Junior Professor of Anatomy and Director of the Histological Laboratory, University of Michigan. Authorized Translation from the Second Revised German Edition by HERBERT H. CUSHING, M. D., Demonstrator of Histology and Embryology, Jefferson Medical College, Philadelphia. With 351 Illustrations. Pp. 7 to 501. Philadelphia: W. B. Saunders & Company, 1900. [Price, \$3.50.]

A PERUSAL of this book speedily shows the immense advance that has been made in recent years, not only in our knowledge of the finer structure of the tissues, but also in the technics of microscopical work. Especially is this true in the reading of the chapters on the cell and on the central nervous system. The latest researches are here embodied and, with the clear, and therefore valuable, illustrations, impart an immediate sense of their didactic importance.

The book opens with fifty pages devoted to microscopic technics. This is followed by twenty pages on the cell, especially well illustrated. The minute study of the tissues in general is then considered, and the remainder of the work is devoted to the histology of the special organs. The size of the book but emphasizes its thoroughness; and it is safe to say that it has no superior in the English language.

The translation is capitally done into idiomatic English, and the book-making is of the highest order. The illustrations are beyond reproach.

Hernia: Its Ætiology, Symptoms, and Treatment. By W. McADAM ECCLES, M. S. (Lond.), F. R. C. S. (Eng.), Assistant Surgeon, West London Hospital, etc. Pp. xiv-231. New York: William Wood & Company, 1900.

THIS book, while not purporting to be an exhaustive review of the entire subject of hernia, covers the field exceptionally well. The special anatomy of each variety of hernia is thoroughly discussed, and its ætiology, symptoms, and treatment are considered. In operating for inguinal hernia, the author closes the canal by suturing the internal oblique and transversalis muscles to Poirson's ligament, leaving the spermatic cord above the canal, somewhat after the method of Halsted and Bassini. The various recognized operations for radical cure are each briefly discussed, while full consideration is given to the rarer forms of hernia. The author believes that it is wise for those who perform heavy labor to wear a truss after an operation.

The book is printed on heavy toned paper, and is ve

well illustrated by photographs and drawings. Every surgeon will be interested in reading it, and we believe it to be one of the few books well suited for students' use.

A Practical Treatise on Genito-urinary and Venereal Diseases and Syphilis. By ROBERT W. TAYLOR, A. M., M. D., Clinical Professor of Venereal Diseases at the College of Physicians and Surgeons (Columbia University), New York, etc. Second Edition, thoroughly Revised. With 138 Illustrations and 27 Plates in Colors and Monotone. Pp. 5 to 722. New York and Philadelphia: Lea Brothers & Company, 1900.

OUR high opinion of this work was expressed at the time of the appearance of its first edition, and certainly it is the ablest of the modern treatises upon venereal diseases. Of the second edition it need only be said that it presents the good qualities of its predecessor together with the revision and correction that three years have required. One who pretends to keep in touch with the subjects of genito-urinary and venereal diseases will scarcely be without Dr. Taylor's book.

1 Manual of Syphilis and the Venereal Diseases. By JAMES NEVINS HYDE, A. M., M. D., Professor of Skin, Genito-urinary, and Venereal Diseases, Rush Medical College, Chicago, etc., and FRANK HUGH MONTGOMERY, M. D., Associate Professor of Skin, Genito-urinary, and Venereal Diseases, Rush Medical College, Chicago, etc. Second Edition, Revised and Enlarged. With 58 Illustrations in the Text and 19 Full-page Lithographic Plates. Pp. 9 to 594. Philadelphia: W. B. Saunders & Company, 1900. [Price, \$4.]

THE second edition of this work finds it increased in the number of pages and in many parts rewritten. The entire portion devoted to the subject of gonorrhoea has been revised and is as modern and scientific as is to be found in any treatise on the subject. The chapters on syphilis, too, have been subjected to correction and amendment, and are in themselves complete and all-embracing. The attitude of the authors that syphilitic disease does not prove fatal in nearly the proportion of instances in which tuberculosis does, will, we think, receive professional sanction.

A number of new illustrations have been added to the book, rendering it more attractive. For the specialist, the student, and the practitioner we consider this work one of exceptional usefulness.

1 Practical Treatise on Medical Diagnosis for Students and Physicians. By JOHN H. MUSSER, M. D., Professor of Clinical Medicine in the University of Pennsylvania; Physician to the Philadelphia and the Presbyterian Hospitals, etc. Fourth Edition, Revised and Enlarged. Illustrated with 250 Woodcuts and 49 Colored Plates. Philadelphia and New York: Lea Brothers & Co., 1900.

In his fourth edition the author brings the subject to its most recent development. Marked as it is by some considerable revision and addition, it may be said that the work is a very valuable exposition of modern diagnostic methods. The book, we believe, is by this time well known, but to those unfamiliar with it we may safely commend it as most reliable and exhaustive.

W. B. Saunders' Pocket Medical Formulary, with an Appendix. By WILLIAM M. POWELL, M. D. Sixth Edition,

thoroughly Revised. Philadelphia: W. B. Saunders & Company, 1900.

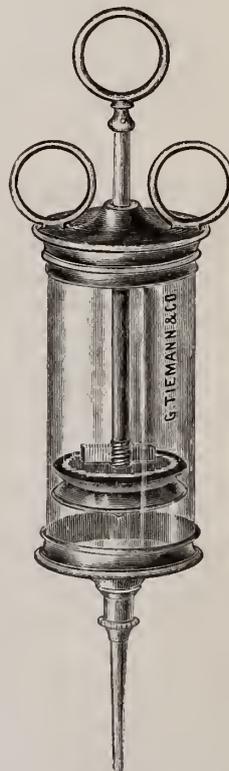

THIS work, intended to be carried about by the physician, contains 1,844 prescriptions, mainly from recognized authorities, arranged in alphabetical order according to diseases. An obstetrical table, a diet list, methods of treating asphyxia, a table of incompatibles, a "surgical remembrancer," and other data of a similar nature are also contained in the book. We have no doubt that a work of this kind will find a useful field, for it is well done and can be made of practical service by any medical man.

New Inventions, etc.

A NEW AURAL SYRINGE.*

By J. H. BRYAN, M. D.

THE syringe which I have the pleasure of showing you to-day is an extremely simple one, consisting of a glass barrel with metal attachments. It is devoid of the many drawbacks which are common to the various instruments thus far placed on the market, in that it can be kept thoroughly aseptic, and it does not leak after boiling, a defect so frequently met with in the ordinary ear syringe.

The new composition fastening of the metal and glass is firm, and it can be boiled, as well as the composition packing of the piston.

The piston can be tightened or loosened by drawing the piston-rod clear up where the bracket on the packing plate locks between two brackets on the inside of the top cap. By turning the piston-rod to the left the packing is screwed together, which expands it, while by turning to the right the packing is loosened. It is desirable when the instrument is not in use to keep the packing loose.

*Shown at the Twenty-second Annual Congress of the American Laryngological Association.

Miscellany.

The Significance of the Hydrostatic Test of Still Birth.—Dr. T. Dilworth writes to the *British Medical Journal* for December 1st to report the case of an inquest held recently on the body of a female illegitimate child, which was exhumed after being buried ten days. The evidence at the inquest went to show that the child was born rather precipitately, but the woman was attended by some neighboring woman first, then by a medical man, and finally by the parish nurse, who all saw the baby alive, though weakly. The child lived about five hours.

At the post-mortem examination, which was done by Dr. Dilworth, assisted by the medical man who attended the mother, they found that the body presented the appearance of a child born at full term, and fairly well developed. On opening the chest the lungs were found collapsed, not filling the chest cavity, and in a state of complete "atelectasis." They resorted to the hydrostatic test, and found that the lungs sank when both were immersed together, when immersed separately, or even when small portions were thrown in; in fact, they gave the indications of a still-born child.

Dr. Dilworth says: "I was obliged to confess to the coroner that had I not the indisputable evidence of five different people on oath that the child lived five hours, I should be compelled to swear that the child was still-born, and had never breathed. The only explanation, I suppose, is that the infant kept its feeble hold of life by whatever aeration the blood received through the trachea and the larger bronchi."

A Bill to Regulate the Relation of Gas Companies to the Public Health.—A bill has been introduced in the assembly at Albany by Mr. Harbruger providing that gas companies in the State shall make sworn reports twice each year to the State board of health of the amount of gas made and sold, in cubic feet; amount of gas consumed in works or offices, in cubic feet; amount of gas unaccounted for, in cubic feet; length of mains in use; gas unaccounted for per mile of main, in cubic feet; percentage of gas unaccounted for to total output.

Every report shall also show for the period covered by it what claims for damage to persons or property resulting from the leakage of gas in distribution have been adjusted, compromised, or settled out of court, by or on behalf of the companies; also, what judgments for loss or damage resulting from gas leakage have been entered against them; also, what suits against them, based on the allegation of damage to persons or property from gas leakage, are pending.

It shall be the duty of the State board of health to transmit copies of such reports to the mayors of cities and the boards of health of towns in which the companies operate, accompanied with such suggestions as the board may consider necessary for the public welfare and the better protection of life and health. It shall also be the duty of the State board of health to report to the Governor, from time to time, such measures for the regulation of gas distribution as may be warranted by information before it.

Cigarettes and Insanity.—Dr. Carlos MacDonald, in the trial for murder at White Plains, N. Y., of Burnz, stated in rebuttal of the defense set up (viz., that the accused was insane as a consequence of excessive cigar-

ette smoking) that during the past thirty years he had examined upwards of fifty thousand persons as to their sanity, and he had never found a single case of insanity which was in any way attributable to cigarettes.

The Danger of the Eclipse of Quinine in Malarial Disease.—Mr. A. H. Hanley, F. R. C. S. I. (*Journal of Tropical Medicine*, December, 1900), fears that the present attention to the mosquito may cause people to neglect quinine. Any one who goes to Southern Nigeria and expects to steer clear of fever by use of the mosquito net at night will, he fears, in many cases, be soon disillusioned. The anopheles here attack one both day and night. In his practice out there he has had to do long journeys in a boat at night, and for twenty-six miles has been exposed to the attacks of mosquitoes and other pests; but, thanks to ten grains of quinine, taken either when starting or on arrival, he has for years escaped fever. After fifteen years' experience of Southern Nigeria, he cannot speak too strongly of quinine as a prophylactic, and he still advises all comers to take quinine as heretofore till such time as the place in which they reside is free from anopheles. He deprecates the tendency to put the quinine bottle on one side and depend on the mosquito net. The people who do that either do not believe in quinine as a prophylactic, or fail to see that the mosquito net at night confers but partial protection.

Extremes Meet.—The *Medical Record* for January 26th reports the case of twins, born, respectively, a few moments before midnight on December 31, 1900, and a few moments after midnight on January 1, 1901. Twins are occasionally born with a long interval between them, but a century! oh! Perhaps, after all, this is only a plant—a century plant. If there is to be any doubt as to their names, we would suggest Fin-de-siècle and Up-to-date.

The Temptation of Forceps.—According to the *West London Medical Journal* for January, Professor A. R. Simpson is responsible for the following story:

An old practitioner, Dr. Gideon Gray, and his son set out one day on a long round of some fifty or sixty miles, with the possibility of the latter being left in attendance on a shepherd's wife. Just at starting the following discussion took place: "What's that ye're pittin' i' the gig, laddie?" "It's the forceps." "Did ye say your prayers this morning?" "Yes; why did you ask that?" "Why? My man! because it's nae guid praying 'Lead us not into temptation,' if ye tak' foreeps wi' ye tae a midwifery ease."

The First Woman M. D. in Germany.—The *Medical Age* for January 10th tells us that it was in the year 1754 that the degree of M. D. was first conferred on a woman in Germany. The *Vossische Zeitung* for July 18, 1754, mentions that the medical faculty of the University of Halle had granted the degree of M. D. to Mrs. Dorothea Christiana Erxleben after she had passed the examination with distinction. This lady had been an apprentice of her father, a well-known medical practitioner at Quedlinburg, and as she could not matriculate at a university, she learned medicine by reading only. By a royal decree of Frederick the Great she was then recommended to the faculty of Halle as a candidate for graduation, but she presented herself only after the death of her husband. She also published an essay on the utility of learning for the female sex.

Original Communications.

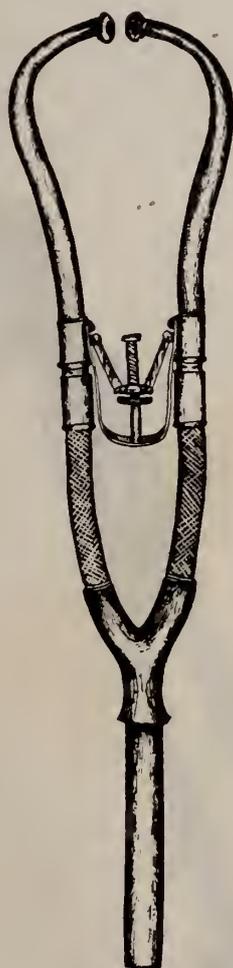

STETHOPHONOMETRY.

By ALBERT ABRAMS, A. M., M. D.,

SAN FRANCISCO, CAL.

To those of us habitually engaged in the examination of the chest, it has no doubt been a source of regret that we are in the possession of no accurate means of registering the intensity of the heart sounds in health and disease, as well as the auscultatory lung phenomena.

There are different factors which normally determine the loudness of the heart tones. One factor is the varying conductivity of the different structures in the chest wall and between the thoracic wall and the heart. The chief factor, however, is the strength of the heart's action. Auscultation of the heart tones in the conventional manner not infrequently affords us no indication of cardiac

strength, if reliance is to be placed on the intensity of the tones in their selective propagation to different parts of the chest.

I have often been struck by the loudness of the heart tones in emaciated individuals in whom the action of the heart was found to be feeble, as determined by the sphygmomanometer and sphygmograph. In convalescents

from typhoid fever, the foregoing fact has been specially emphasized in not a few instances. In anæmics, we often hear very loud tones, even though the blood pressure is low; and again in dilatation of the stomach, when that organ approximates the cardiac area, the tones by mere resonance are loud, even though the strength of the heart is reduced. In many emaciated persons it often happens that the heart tones are conveyed to the interscapular region, to the epigastrium, and even to the head without any corresponding increase in the force of the heart. In such instances the thorax is practically a resonator. If then, in certain instances, auscultation is no trustworthy index to the force of the heart, have we not in the sphygmomanometer and sphygmograph clinical instruments of sufficient reliability to gauge the blood pressure? Unfortunately, in the application of these instruments we must contend with the objectionable personal equation, and content ourselves with the determination of the blood pressure in the systemic circulation only. When the phonograph was first introduced, I thought I saw in that instrument the consummation of my hopes, but after considerable experimentation it proved useless. In my *Manual of Diagnosis** the results are expressed as follows: "In my investigations, which were varied in every manner possible, the recording of heart sounds was practically impossible. The fault rests with the phonograph. There is no question about the sensitiveness of the diaphragm for recording even the feeblest sounds, but the difficulty lies in reproduction. Even loud sounds emanating from the chest are with difficulty detected by an ear accustomed to the phonograph. When the reproducing needle is adjusted to the revolving wax cylinder a hissing sound is heard, the result of friction between the needle and the wax. It is this sound which interferes with proper reproduction. If this objection were obviated, the phonograph would prove an ideal instrument in physical diagnosis."

Subsequently I reported† the following two methods for measuring the heart tones: "The following method is suggested for its simplicity. It is only relatively accurate, and is based on the simple physical principle that the intensity of sound varies inversely as the square of the distance from the sounding body, hence the distance to which a heart sound may be heard depends upon its intensity, ignoring of course those adventitious causes of propitious conductivity. Between the area auscultated and the stethoscope a medium is interposed. Experiment has taught me that one of the best media is partially vulcanized rubber in the form of a rod, and just sufficiently soft not to interfere with convenient manipulation. Such rods may be purchased in any store where rubber goods are sold. The circumference of the rods must equal the calibre of the pectoral end of the stethoscope in which they are to be inserted. The degree of insertion must be regulated by a notch cut into the rubber. The

* *Manual of Clinical Diagnosis*. Third edition, 1894.

† *Medical News*, July 8, 1899.

object of this regulation is to insure uniformity of results in the examination of individual patients. The rods may be of different sizes, varying in length from six to twenty-six centimetres, or even of greater length. Before auscultating the heart tones by this method, we must first mark on the chest the different points in the præcordial region where the heart tones are heard with the maximum degree of intensity. Over each ostium, we auscultate with the rod inserted into the end of the stethoscope, beginning with a rod of medium length and gradually increasing the length of the rod until one is attained through which the heart tones are no longer conducted. The tubes are numbered, and a record may be made in our case book after the following formula:

Mitral I tone.	6
“ II tone.	5
Aortic I tone.	4
“ II tone.	5
Tricuspid I tone.	6
“ II tone.	4
Pulmonary I tone.	4
“ II tone.	5

According to the foregoing formula we conclude the following: That with a rod (No. 6) which is twenty-six

thin persons, owing to the increased conductivity of the thoracic tissues. As before, one marks on the chest wall the different situations where the heart tones corresponding to each ostium, are heard loudest, and then proceeds in different directions until the sounds are no longer audible. The distance to which the sounds are propagated is marked and measured. The directions in which the sounds are auscultated have been determined empirically as follows:

Mitral tones: Auscultate along a line on a level with the apex beat to the left axillary region.

Tricuspid tones: Auscultate along a line extending from the point of auscultation to the right axillary region.

Aortic tones: Along a line on a level with the point of auscultation to the right axillary region.

Pulmonic tones: From the point of auscultation to the left axillary region. The tricuspid and mitral tones are best conducted downward by the liver, but as a distinction between the mitral and tricuspid tones over the hepatic region is impossible, this direction cannot be employed. I will mention, parenthetically, that the liver is an excellent conductor of the heart tones, and that when they are no longer audible by auscultation we can safely

centimetres in length, we may still be able to hear the following tones: Mitral systolic and tricuspid systolic tones. A similar interpretation may be deduced from the other numbers. These figures possess no value for general application, as the degree of transmission is dependent on the character of the stethoscope as well as on the length of the rod employed. Each observer must cut his own rods of different lengths. With some kinds of stethoscopes the first mitral and tricuspid tones are still heard with rods fully thirty centimetres in length, whereas, with other kinds, a rod of half the length will no longer transmit the same tones.

In some instances another method may be adopted. It is less reliable than the former method, especially in

conclude that the lower border of the liver has been reached.”

A reasonable experience with the methods just cited demonstrates the inconvenience and impracticability of the rod method, and the relative inaccuracy of the second

method. Attempts were therefore made to simplify stethophonometry by the construction of a stethophonometer,* which is herewith illustrated.

It is constructed on the disc valve principle, weighs about two ounces, and is composed wholly of hard rubber. There are three perforated discs in close apposition, the middle disc being made to revolve by means of a handle attachment, so that its opening may be made to approach or recede from the opening in the two other discs. The greater the encroachment on the opening by the middle disc, the greater will be the resistance offered to the transmission of the sound waves. On the face of the disc nearest the auscultator, is a scale by which the intensity of the chest sounds may be measured. On one side of the discs, the bell of the stethoscope is affixed, and, on the other side, a plug, the size of which may be varied to fit any stethoscope. This plug is perforated, and in the perforation may be fitted a rubber cork, if necessary, to offer still further resistance to sound. The latter expedient, however, is rarely necessary. The stethophonometric attachment can easily be removed when it is found necessary to carry out the conventional method of auscultation.

The employment of such an instrument will no doubt serve to add greater scientific value to our clinical examinations in recording the intensity of the acoustic phenomena associated with the heart and lungs. In determining the relative loudness of the breath sounds, for instance, over the pulmonary apices, it will prove invaluable. Another index to its employment in lung auscultation is the following: After gauging the instrument so that the vesicular murmur is no longer heard, auscultation is successively practised over different areas of the thorax. It follows that if breath sounds are conducted to the ear at some particular area, we have at that area, either exaggerated breathing, bronchial respiration, or some other anomalous acoustic phenomenon. Such deductions necessarily postulate familiarity with the varying degree of breath sounds in different parts of the chest. No matter how well trained the ear may be in auscultation, it can never replace a carefully gauged instrument.

By aid of the stethophonometer, I can confirm the work of Dr. S. R. Creighton, extensively reported in the recent admirable work of Cabot on Physical Diagnosis, viz.: That the relative intensity of the pulmonic second sound, when compared with the second aortic sound, varies a great deal at different periods of life. The observations of Creighton are important, as they serve to correct the popular error current in text-books, that the aortic sound in health is always louder than the pulmonic second sound. At present, I am at work with the stethophonometer in an attempt to establish a distinction between purely cardiomuscular and valve tones. This much I am prepared to say, viz: That in gauging the vigor of the failing myocardium, the greatest reliance is to be placed on the early evanescence of the first tones over the pulmonic and aortic areas respectively. In

using the stethophonometer, the mode of auscultation must be uniform. This relates to the position of the patient, as well as to varying conditions which, in the physiological and pathological states, necessarily modify the intensity of the heart sounds.

SEPTICÆMIA IN YOUNG CHICKENS.

BY LEO F. RETTGER, M. A., M. D.,

YALE UNIVERSITY, NEW HAVEN, CONN.

IN the *New York Medical Journal* for May 26, 1900, I published the results of some observations I made on a peculiar case of septicæmia in young chickens. In this article I shall briefly summarize the facts as given, and in addition give the results of a later investigation of the same subject.

The disease occurred among young chickens from two to three weeks old. Of a brood of seventeen chicks all

but three were sick, and of these all but three died. Grown chickens were immune. The symptoms were the same in each case. There was a loss of appetite and the chick grew sluggish; the feathers became rough and diarrhœa prevailed. Later, the chick stood with drooping wings, the neck and legs appearing unusually long and slender. Finally it lay on its side, with outstretched wings. The mouth and throat seemed normal and there was no visible sign of pain. On post-mortem examination, the chick was very poor; the crop was empty; the intestines were pale and almost empty; the liver was pale, with the exception of a few dark-red patches and streaks. From the liver a pure bacillus culture was obtained. This organism is a motile, non-liquefying, non-chromogenic, aerobic, and facultative anaerobic bacillus with slightly rounded ends. When grown on agar, it is from one to two micra long, from 0.3 to 0.5 of a micron broad, and usually occurs singly. It grows rapidly on ordinary media, best at incubator temperature. It stains with the

*Made for me after an original design by the Shoenberg Electrical Company, E. Spreckels Building, San Francisco, Cal.

ordinary aniline dyes, but not by Gram's method. Four chicks from two to four weeks old were inoculated subcutaneously with a bouillon culture of the bacillus. In about two days after the inoculation there were symptoms of disease resembling those of the original brood. Two of the chicks recovered in a few days; the remaining two died, the one in four, and the other in a little less than five days. The same organism was obtained from the blood as originally found.

Thus far my observations were confined to this brood of seventeen chicks. Whether the disease was common and ever became a real epidemic, I was unable to say, as these were the only young chickens in that vicinity, and there was little chance of spreading the disease.

While at Winona Lake last summer, Mr. Bass, a gardener, called my attention to a disease which was rapidly exterminating his young chickens. Of forty chicks (four broods), all died but five. They were attacked, and died, while between one and four weeks old. Of those that were sick, only one recovered. They were given fowl cholera treatment, and were moved frequently into new boxes which had been washed with lime. The disease took its course, however. Another brood of fifteen chicks began to show symptoms of the same disease when hardly a week old. All but three died before they were three weeks old. Soon afterward two broods of thirty-three chicks contracted the disease, and in less than three weeks all but ten succumbed.

At about the same time, two farms adjoining that of Mr. Bass became a prey to this epidemic. Of a large number of young chickens that were attacked, about eighty per cent. died. On one of these farms hogs were allowed to run practically at large. They all remained entirely immune. Neither did the epidemic visibly affect any of the chickens which were more than four or five weeks old.

The symptoms corresponded almost perfectly to those of the case originally observed. The only differences which I could note were these: In the first stages of the later infection the chicks seemed to be feverish and more or less thirsty; and, secondly, the progress of the disease was more rapid than in the first case observed.

From the liver of the chicks I obtained a bacillus, which, on examination, corresponded in almost every detail to that obtained from the original brood of seventeen chicks. The development, however, on artificial media, and especially on potato, was more rapid than that of the first culture. This was due, in all probability, to the greater virulence and vigor of the newer bacillus.

With a pure culture of this bacillus I inoculated two chicks scarcely two weeks old, subcutaneously. A third chick of the same age was kept separate, for control. Within two days both of the inoculated chicks appeared sick. The disease progressed rapidly, and in about three days the chicks died. The disease took the same course as the epidemic, except that it was a little more rapid in

its progress. (The accompanying photograph was taken from thirty to forty-five minutes before the chicks died.) From the liver of these chicks I obtained a pure culture of the bacillus in question.

That this disease is an epidemic whose importance cannot be easily overlooked, there is no doubt; and the problem of combating it is one of vital interest to the farmer and others who are engaged in poultry raising.

A NEW PORTABLE AND INEXPENSIVE OPHTHALMOMETER.*

By WILLIAM F. AIKEN, M. D.,

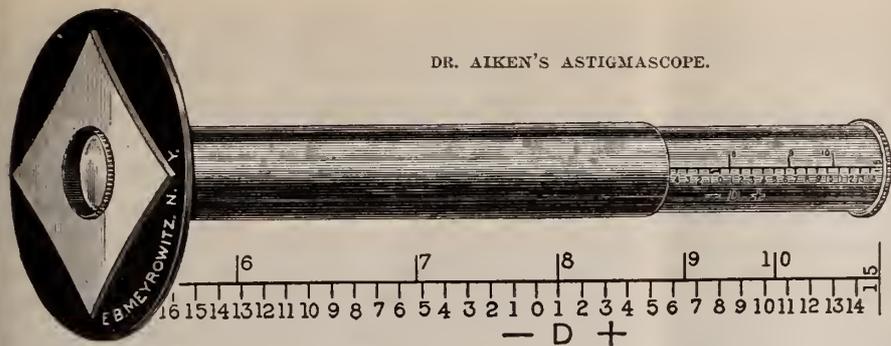

SAVANNAH, GA.

It is a fundamental principle in physics that the refinement of an instrument of precision beyond that point where attainable results are useful is both needless and extravagant. Machines and instruments of all kinds must, like organisms, compete with rivals for survival; and, in this contest, economic as well as technical principles are involved. Therefore, in designing any piece of mechanism, an attempt should be made to nicely balance these two principles in the organization of the machine.

With these truths in mind let us consider briefly the utilities and economics of the prevailing types of ophthalmometer, noting especially those heavy instruments requiring a supporting table or similar fixed stand, and let us study them solely with reference to routine refraction work in the office or dispensary. They are constructed to measure with great nicety the corneal curvature by means of mires of considerable size, movable along an arc of considerable radius, the reflected images being examined through a telescope of considerable length wherein doubling of those images is accomplished by means of an expensive prism. Moreover, all these instruments carry attachments, some of them involving flat or curved discs of large size, whereby the axis of an astigmatism may be read in degrees of the circle. The total bulk and weight are materially augmented by these attachments, not to mention expense of construction.

Here, then, is an elaborate apparatus for very exactly measuring corneal astigmatism, and for showing the axes upon a graduated circle of such great radius that a single degree of variation might be detected thereon. All these refinements, which almost suggest those of a transit instrument, add bulk, entail labor in manufacture, and sacrifice time in manipulation. And to what end? That a painstaking observer shall be able to secure a reading which he can be reasonably sure is not more than one and a half dioptries out of the way as compared with the actual glass needed by the patient, and an indicated axis for that glass not more than, say, fifteen degrees at variance with the requirements of the patient's eye. The instrument is more accurate than its results are applicable,

*Read in part before the Georgia Medical Society, December 4, 1900.

minishing the size of the instrument to such an extent that it may be made portable and freed from the drawbacks aforementioned. Thus, if positive determination of axis to within less than an angle appreciable by the unaided eye is impossible, the entire axis measuring equipment may be done away with; if smaller mires closer to the cornea

in short. And the gratuitous perfection is obtained at the cost of bulk that in turn means an immovable instrument to which both light and patient must be brought and attached—another shifting around of the patient, another lot of instructions and explanations, and time lost. We are all familiar with the demonstrating ophthalmom-

will yield results approximating as nearly to the astigmatism to be corrected as do large mires on an arc of longer radius, we may employ profitably the small mires, dispensing with the large arc, etc. The same will hold good for a shortened telescope and simplified prism. In other words, we can thus make an instrument of no less *practical* accuracy and with the added advantages of portability and facility in its employment, an ophthalmometer adapted strictly to the work of fitting glasses, while leaving to the larger instrument the wide field of scientific ophthalmometry in the truest sense. I may best illustrate my meaning by comparison. A linen merchant does not use a compound microscope with oil immersion objective as a thread counter, neither does a mariner employ an astronomical altitude and azimuth instrument in lieu of his less delicate but more adaptable sextant.

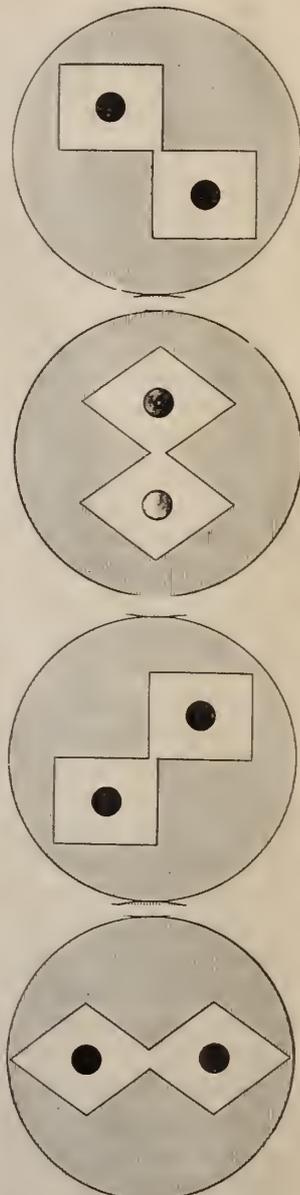

FIG. 2.

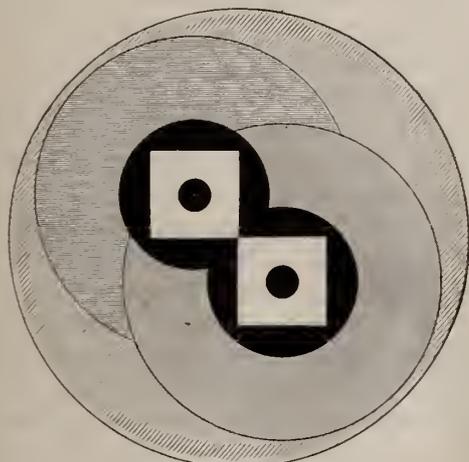

FIG. 1.

scope of Mr. Brudenell Carter, with its chin-rest, lenses, lamp, and mirror arranged on a four-foot table, as figured in Dr. Bull's edition of Soelberg Wells, but we do not avail ourselves of it in our office routine, preferring a small hand instrument.

The principle I wish to emphasize is this: that several

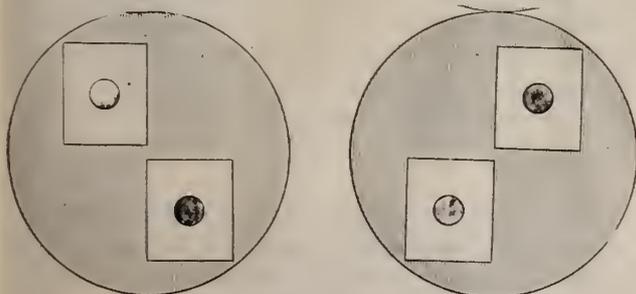

FIG. 3.

features of the type of ophthalmometer we have been considering may be dispensed with, in so far as they add nothing to the useful information supplied, thereby di-

NOTE.—In Fig. 2 the second diagram should show the obtuse angles just in contact, not overlapping. In Fig. 3 the vertical alignment is correctly shown, but the rectangles should be elongated horizontally instead of vertically as depicted. All six positions in Figs. 2 and 3 represent astigmatism "with the rule."

An instrument organized on the lines indicated in the foregoing analysis, I have been maturing for a considerable time. As first conceived, it was for use merely as a rapid guide and time-saver preliminary to the truly accurate methods of the shadow test and trial lenses. Constructed for me by Mr. E. B. Meyrowitz, it proved more than I had expected when I named it an "astigmascope" in modest avoidance of the more ambitious "-meter" ter-

mination. As a matter of fact, it has proved in my hands perfectly reliable as to measurements of the corneal convexity. The accompanying cuts, for which I am indebted to Mr. E. B. Meyrowitz, will explain themselves, the principle being that of doubling a square image in the direction of one diagonal, causing opposite corners to touch, and thereby making opposite sides of the square serve as mires forming a cross of perfect figure in the absence of astigmatism in the reflecting surface, and demonstrating any astigmatism by a faulty alignment of one pair of sides, when the other pair at right angles thereto are correctly aligned. The large, brilliant images facilitate the detection of even slight displacements, while no counting of "steps" or other minute spaces is called for, a scale on the draw-tube giving the reading for each axis when the arms of the cross lying in that meridian are in line. It is as if four mires were used at once, two in each of two meridians at right angles to each other, whereby it is possible to compare the two principal meridians of an astigmatism as seen at the same time in one picture.

The range of the instrument as a spherometer is from a curvature like that of a large bicycle-bearing ball ($r=5.5$ millimetres) to a sphere larger than the globe of the eye ($r=13$ millimetres). It may thus serve to measure many conical corneas at the centre and to make ophthalmometric records of microphthalmus, etc. The astigmatoscope is so constructed that the mire and ebonite disc are detachable, allowing the instrument to go in a pocket case of 6x3x1 inches inside measurement. It is used with the patient in the position for ophthalmoscopy, the light being placed a little more to the side. Thus, one may complete both ophthalmoscopic and astigmatoscopic examinations without changing the patient's position. The images are made to come together by advancing the mire toward the cornea, at the same time elongating the drawtube to suit the changed proportions of the conjugate foci of the objective, thereby changing the scale reading to that which indicates the corneal curvature of shorter radius necessitating such advance; the reverse is true when the images have to be separated. As I had originally designed, I prefer readings from positions of alignment of the sides of rectangular images, but the scale is so calculated that it reads correctly from positions of contact of the acute and obtuse angles of the rhomboidal figures obtained when the diagonals of the mire lie along the principal meridians of an astigmatic cornea; only, in that case, accurate contact is slightly harder to note than the alignment of the long brilliant sides of the rectangles forming the "cross."

The incurved sides of the mire are calculated to neutralize the ellipsoidal bulging that a square mire would suffer when reflected in the cornea. Being adapted for a region of some 12 D. about the 7.8 millimetre point, there exists some slight curving at the ends of the scale, but this in nowise affects the scale readings for the angles. Irregular astigmatism will produce distortions easily under-

stood. The rotatable black ebonite disc serving as a background for the ivory mire also acts as support for the front of the instrument, being encircled by the observer's thumb and forefinger of the hand farthest from the light, the remaining fingers of the same hand forming a screen for the patient's other eye, while the little finger rests between the patient's eyebrows. This hand moves the mire nearer and farther as regards the cornea under examination, the other hand grasping the draw-tube and maintaining a clear focus while rotating the instrument; at the same time this hand shields the observer's eyes from the light. A little "knack" is requisite and may be acquired in about as many days as the ophthalmoscope takes weeks for mastery. The facility with which the requisite skill may be attained, and the low cost of the instrument (\$15), make a practical ophthalmometer available for every student of ophthalmology and for the general practitioner whose location at a distance from an ophthalmic surgeon necessitates a critical selection of those cases of headache, etc., which he shall refer to the latter. For the busy ophthalmologist it will serve as a ready indicator of the defect sought and the approximate glass, saving much guesswork at the outset when using the trial lenses, and consuming less time than the larger ophthalmometers. Simple, portable, saving time and office space, independent of light connection, inexpensive, and yet possessing an accuracy yielding utility of findings commensurate with that of the larger instruments, it will, I hope, prove of considerable service to my fellow practitioners.

I should add that the only other portable ophthalmometer with which I am personally familiar, that of Reid, possesses, I believe, as many advantages as my astigmatoscope, except that its more complicated construction entails greater expensiveness. I desire further to state that the scale on the astigmatoscope has been empirically verified at a number of points from zero to the extreme ends, to insure correction for the ellipsoidal form of the corneal image, for the separation of the prisms from the objective, thickness of glass, etc., while spherical and chromatic aberration are practically eliminated by the neutralizing effect of the prisms placed with bases out behind the biconvex objective, all of these problems having been given much time and consideration.

228 OGLETHORPE AVENUE, E.

COMBINED SURGICAL OPERATIONS IN FEMALE SUBJECTS AT A SINGLE SÉANCE.

By R. STANSBURY SUTTON, M. D., LL. D.,

PITTSBURGH, PA.

A QUARTER of a century ago it was customary, except probably in the Woman's Hospital in New York when a female patient presented herself with a laceration of the cervix and perinæum, to repair the cervix and hold her over for repair of the perinæum at a later period.

If a female patient required four or five distinct surgical procedures, until within a very recent period she was four or five, or even six, months under the care of a surgeon, and about two thirds of the time in bed. However, as time progressed, it became customary to curette the endometrium and repair a lacerated cervix and perinæum at the same time.

During more recent years it has become the habit with some, probably encouraged more by Edebohls, of New York, than any other American operator, to clean up a case without regard to the number of procedures required.

It is a fact gained by experience that, in a patient in fairly good condition, a long wound will heal with about as much safety and expedition as a short one, provided asepsis has been maintained with reference to both wounds. A multiplicity of short wounds is equivalent to a long wound, provided they involve similar tissues, but in multiple operations dissimilar tissues are involved. Yet it has been found that the long wound composed of dissimilar tissues heals quite as readily.

The next question involved is that of anæsthesia. Some men operate rapidly, while others are "slow as molasses in winter." The former class may complete a series of operations within safe limits for anæsthesia, while the latter class would probably require two days' rations in the operating room.

Collating the facts, that multiple wounds heal kindly, and that manual dexterity can be acquired which enables an operator to complete a series of operations within safe limits of anæsthesia, we are enabled to deduce the warrant for such surgical conduct when a case requiring multiple operations presents itself.

Some years ago our English cousins, as represented by the *British Medical Journal*, almost went into hysterics over the publication by Edebohls of an article on multiple operations at a single *séance*. This is one of those practical subjects which is better demonstrated than theorized upon, and I have selected the cases of fifteen women out of a great many who have undergone multiple operations at my own hands. These cases will now be recited, and the time consumed in each individual case will be given. I may add that, in each instance, a time-keeper was appointed, and the reports are therefore correct.

CASE I.—*Present*, Dr. Stone, Dr. Hunter, and Dr. Ohail. *Name*, Mrs. P., aged forty-two years. *History*: Married twenty-four years; has borne seven children at term, and has had three abortions. She is now a chronic invalid, confined to the bed, and is brought to the hospital on a stretcher. *Operations*: 1. Curettage of the endometrium. 2. Trachelorrhaphy, bilateral. 3. Perinæorrhaphy. 4. Divulsion of the sphincter ani muscle for anal fissure and rigidity of the muscle. 5. Short median incision in the abdominal wall, and removal of the ovaries and tubes from both sides. Wound closed by three or four interrupted silk-worm gut sutures. *Time*: Thirty-six minutes. *Result*: Recovery, with complete restoration to health a few months later.

CASE II.—*Present*, Dr. Stone, Dr. Hunter, and Dr. Ohail. *Name*, Miss A., aged twenty-seven years. *History*: Has recently had an attack of appendicitis. Severe dysmenorrhœa. Uterus retroversed. Almost constant pain in the right iliac region. *Operations and pathology*, October 25, 1894: 1. Dilatation of the cervix uteri and curettage of the endometrium. 2. Two-and-a-half-inch median incision; right ovary and tube and adherent appendix brought into the wound. Ovary and tube were much inflamed. Small patches of lymph were seen over the distal half of the tube. 3. Appendectomy. 4. Removal of the right ovary and tube, followed by careful wiping out of the pelvic cavity with moist sterilized gauze, hot water being poured into the cavity from a pitcher to assist in the cleansing process. 5. Anterior fixation of the fundus uteri with one deeply buried silk-worm gut suture. Wound closed. *Time*: Forty minutes. *Result*: Recovery.

CASE III.—*Present*, Dr. Sutton, Zanesville, Ohio; Dr. Holden, of Ohio; Dr. Stone, and Dr. Hunter. *Name*, Mrs. K., aged twenty-six years. *History*: Laceration of the cervix and introitus vaginæ. Menorrhagia. Painful anal fissure. Has an almost constant uneasiness in the right iliac region. Suffers much from nausea. The appendix is tender upon pressure. *Operations*, November 18, 1894: 1. Curettage of the endometrium. 2. Bilateral trachelorrhaphy. 3. Perinæorrhaphy. 4. Divulsion of the sphincter ani muscle. 5. Appendectomy. *Time*: Forty minutes. *Result*: Uneventful recovery.

CASE IV.—*Present*, Dr. Stone, Dr. Hunter, and Dr. Kniffler. *Name*, Mrs. S., aged thirty years. *History*: Multipara. At her first labor she sustained a bilateral laceration of the cervix and a laceration of the introitus vaginæ. For two years her general health has been breaking. Present condition, endometritis, menorrhagia, proctitis with anal fissure, retroversion of the uterus, obstinate insomnia, and melancholia. *Operations*, January 12, 1896: 1. Curettage of the endometrium. 2. Trachelorrhaphy. 3. Perinæorrhaphy. 4. Divulsion of the sphincter ani muscle. 5. Anterior fixation of the fundus uteri by laparotomy. *Time*: Forty-five minutes. *Result*: Recovery, with eventual restoration to health.

CASE V.—*Present*, Dr. Stone, Dr. Hunter, and Dr. Babb. *Name*, Mrs. W., aged forty-eight years. *History*: Multipara. Some years ago she incurred a laceration of the cervix and introitus vaginæ. In addition, at the present time, she has retroversion, also a proctitis with an anal fissure. *Operations*, April 10, 1896: 1. Curettage of the endometrium. 2. Trachelorrhaphy. 3. Perinæorrhaphy. 4. Divulsion of the sphincter ani muscle. 5. Short median incision followed by anterior fixation of the fundus uteri, at and below the lower angle of the wound, by two buried silk-worm gut sutures. *Time*: Fifty minutes. *Result*: Recovery.

CASE VI.—*Present*, Dr. Stone, Dr. Hunter, Dr. Babb, Dr. Whitten, and Dr. Van Kirk. *Name*, Mrs. C., aged forty-two years. *History*: Multipara. Chronic invalid. Endometritis. Laceration of the cervix; uterus prolapsed and retroverted, and the introitus vaginæ lacerated. *Operations*, April 25, 1896: 1. Curettage of the endometrium. 2. Bilateral trachelorrhaphy. 3. Perinæorrhaphy. 4. Anterior fixation of the fundus uteri by laparotomy. *Time*: Thirty minutes. *Result*: Recovery.

CASE VII.—*Present*, Dr. Stone, Dr. Hunter, and Dr. Babb. *Name*, Mrs. J., aged fifty years. *History*:

Quartipara. Uterus prolapsed and retroverted. Vesicocele. Rectocele, with laceration of the introitus vaginae and cervix uteri. Menorrhagia. *Operations*, March 18, 1897: 1. Curettage of the endometrium. 2. Trachelorrhaphy. 3. Anterior and posterior colporrhaphy. 4. Median abdominal incision. 5. Myomectomy. Interstitial fibroid in the fundus uteri. 6. Anterior fixation of the fundus uteri. All wounds during the operations closed with catgut known as "Edebohls' forty-two-day catgut." *Time*: One hour and fifteen minutes. *Result*: Recovery, with complete restoration to health.

CASE VIII.—*Present*, Dr. Stone, Dr. Hunter, Dr. Babb, and Dr. Kimmel. *Name*, Mrs. B., aged twenty-four years. *History*: Bipara. Sustained at her last labor a bilateral laceration of the cervix and a laceration of the introitus vaginae. She also suffered severely from repeated attacks of biliary colic. *Operations*, September 15, 1897: 1. Curettage of the endometrium. 2. Trachelorrhaphy. 3. Perinaeorrhaphy. 4. Cholecystotomy. Oblique incision, parallel with the right costal border, exposing the gall-bladder, sausage-shaped and containing no fluid, but containing three large gall-stones, set in a row and closely invested by the walls of the gall-bladder. The latter was drawn into the wound, incised and emptied, and the wound stitched into the abdominal wound, and a rubber drain-tube introduced into the gall-bladder. *Time*: Fifty-two minutes. *Result*: Recovery, with complete restoration to health.

CASE IX.—*Present*, Dr. Stone, Dr. Hunter, Dr. Babb, and Dr. Hazlett. *Name*, Mrs. D., aged forty-one years. *History*: Tripara. Youngest child eleven months old. Examination revealed a bilateral laceration of the cervix uteri. Laceration of the perinaeum down to the sphincter ani muscle. Tenderness at McBurney's point. A movable something which can be carried back toward the right renal region, possibly a kidney. Gall-bladder felt; quite tender. She has had biliary colic. *Operations*, January 4, 1898: 1. Curettage of the endometrium, irrigation of the uterine cavity, and swabbing out the same with a saturated solution of iodized phenol. 2. Trachelorrhaphy. The cervical flaps were denuded and the clefts of the lacerations were cleaned out with Schroeder's catlin knife. The denuded surfaces were united with catgut suture. 3. Perinaeorrhaphy, with posterior colporrhaphy. A curvilinear triangular surface, the apex resting half an inch above the vaginal crest, the sides extending obliquely to the carunculæ myrtiformes; the latter, united by a curvilinear incision through the junction of the skin and vaginal mucosa, were denuded with Schroeder's knife. The edges of this triangle, from its apex to the caruncles, were united by interrupted silk sutures, eight to the inch. With a long, curved needle a deep binding suture of silk was passed in the following manner: The point of the needle was entered three eighths of an inch from the edge of the external incision, and carried upward through all the tissues on the right side of the wound. With a turn of the wrist, it was sent through the corresponding tissues of the opposite side, and made to emerge through the skin three eighths of an inch from the opposite edge of the wound, the point of entrance and exit being directly opposite one another. This binding suture was, for the moment, left untied, the needle having been removed. A few interrupted sutures now closed the external wound, and the deep binding suture was tied. The vagina was now thoroughly irrigated with hot water, mopped dry with small cotton balls, and loosely filled with iodoform gauze. The sphincter ani muscle was

divulsed, and the pelvic operations were completed. 4. Exploratory laparotomy. The patient was now placed in the extended dorsal decubitus, and, to determine the enigma concerning the appendix, a short median incision above the pubic symphysis was made, and the fingers were introduced into the peritoneal cavity. The appendix was located, and decided to be normal. But, peeping over an imaginary line drawn across the abdomen transversely to McBurney's point, steadied somewhat by the superimposed hand on the abdominal wall, could be felt the lower end of a thin projection of the right lobe of the liver and the lower end of the gall-bladder. This projection of the lobe of the liver hung down like a small apron, and was that "something" felt in the examination, which could be carried toward the right renal region, suggesting a floating kidney. The wound in the abdominal wall was now closed. 5. Cholecystotomy. A free incision was carried vertically or longitudinally through the right rectus muscle at its upper extremity, and the gall-bladder was drawn into the incision. It was of the shape and thickness of an ordinary sausage, and about five inches in length. The thin projecting edge of the right lobe of the liver hung down over it like an apron, an hepatic abnormality which was to me a curiosity. The gall-bladder contained no liquid of any moment. It was split open at its dome and five large gall-stones were extracted. They averaged three quarters of an inch in diameter, were set in a row and were all fasciculated. The opening in the gall-bladder was stitched to the deeper layers of the abdominal wound at its upper angle. A soft rubber drainage tube was inserted into the gall-bladder, and the remainder of the abdominal wound was closed. *Time*: One hour and thirty-five minutes on the operating table. *Result*: Recovery, with complete restoration to health.

CASE X.—*Present*, Dr. Stone, Dr. Hunter, and Dr. Ahlers. *Name*, Mrs. H., aged thirty-seven years. *History*: Multipara. Uterus retroverted. Endometritis with bilateral laceration of the cervix and laceration of the introitus vaginae. Painful anal fissure. *Operations*: 1. Curettage of the endometrium. 2. Trachelorrhaphy. 3. Perinaeorrhaphy. 4. Division of the sphincter ani muscle. 5. Laparotomy, followed by anterior fixation of the fundus uteri. *Time*: Forty-five minutes. *Result*: Recovery, with restoration to health.

CASE XI.—*Present*, Dr. Stone, Dr. Smith, and Dr. Wilson. *Name*, Mrs. P., aged twenty-eight years. *History*: Bipara. Uterus retroverted. Endometritis, with menorrhagia. Bilateral laceration of the cervix. Laceration of the introitus vaginae. Painful anal fissure. *Operations*, March 7, 1899: 1. Curettage of the endometrium. 2. Bilateral trachelorrhaphy. 3. Perinaeorrhaphy. 4. The edge of the knife drawn through the base of a painful fissure and the muscle divulsed. Laparotomy, followed by anterior fixation of the fundus uteri. *Time*: Forty-six minutes. *Result*: Recovery with complete restoration to health.

CASE XII.—*Present*, Dr. Stone, Dr. Babb, Dr. Rankin, and Dr. Bippus. *Name*, Mrs. K., aged thirty-five years. *History*: Quartipara. One abortion. Last confinement four years ago. Has been in bad health for ten years. Chronic endometritis, salpingitis, and oophoritis. Bilateral laceration of the cervix uteri. Laceration of the perinaeum. Painful anal fissure. *Operations*, September 9, 1899: 1. Curettage of the endometrium. 2. Trachelorrhaphy. 3. Perinaeorrhaphy. 4. Divulsion of the sphincter ani muscle. 5. Laparotomy, followed by removal of the uterine appendages. *Time*: Forty

eight minutes. *Result*: Recovery, with restoration to health.

CASE XIII.—*Present*, Dr. Stone and Dr. Hunter. *Name*, Mrs. D., aged thirty-six years. *History*: Septipara. Endometritis. Slight laceration of the cervix. Deep laceration of the introitus vaginae. One large, painful hæmorrhoid. *Operations*, September 11, 1899: 1. Dilatation of the cervix with Ellinger's dilator, followed by curettage of the endometrium and a puncture of the body of the uterus, at the fundus, through which the curette can readily be passed and felt through the abdominal wall. 2. Perinæorrhaphy. 3. Divulsion of the sphincter ani muscle and removal of the hæmorrhoid. 4. Laparotomy, followed by the closure of the wound in the fundus uteri with Lambert sutures and anterior fixation of the fundus. *Time*: One hour on the operating table. *Result*: Recovery, with complete restoration to health. At the time of this writing, January 24, 1901, the patient is two months pregnant.

CASE XIV.—*Present*, Dr. Stone, Dr. Hunter, Dr. Stewart, and others. *Name*, Mrs. I., aged thirty-five years. *History*: Bipara. Last labor five years ago, after which she developed hystero-epilepsy. Laceration of the introitus vaginae. Bilateral laceration of the cervix. Chronic endometritis, salpingitis, and ovaritis, with adhesions. Anal fissure. *Operations*, April 12, 1900: 1. Curettage of the endometrium. 2. Trachelorrhaphy. 3. Perinæorrhaphy. 4. Divulsion of the sphincter ani muscle. 5. Laparotomy, followed by the removal of the uterine appendages on both sides. *Time*: Forty-five minutes. *Result*: Recovery, with future restoration to health.

CASE XV.—*Present*, Dr. Stone, Dr. Foster, Dr. Hall, and others. *Name*, Mrs. D., aged thirty-one years. *History*: Feeble. Chronic invalid. Anal fissures. Laceration of the introitus vaginae. Uterus retroverted. Bilateral laceration of the cervix. Chronic endometritis, salpingitis, and ovaritis, with adhesions. *Operations*, October 3, 1900: 1. Curettage of the endometrium. swabbing out the uterine cavity with a saturated solution of iodized phenol. 2. Trachelorrhaphy. 3. Perinæorrhaphy. 4. Divulsion of the sphincter ani muscle. 5. Laparotomy, followed by the removal of the uterine appendages. 6. Anterior fixation of the fundus uteri. *Time*: Forty-five minutes. *Result*: Recovery.

This, gentlemen, finishes the demonstration which is respectfully submitted to your honorable body.

THE NORMAL DECLINATIONS OF THE RETINAL MERIDIANS.

By GEORGE T. STEVENS, M. D., Ph. D.,

NEW YORK.

WITH the advance in practical knowledge of the subject of declination which arises from continued observation and experience, the importance of the subject is seen to be increased in proportion as acquaintance with it becomes more accurate and more extensive. It is not necessary to compare the science of declination with heterophoria, but it is important to know that the subjects are so intimately associated and that they are so mutually interdependent that the study of one cannot be successfully pursued except by the help of the other.

In my earlier contributions to the subject I have emphasized many of the disturbances, both visual and general, which may arise from anomalous declinations. A larger experience and more adequately devised measures for the correction of such anomalies have served to confirm the view that these conditions are of vital importance, not only in local ophthalmology, but in the realm of general affections of the body.

Experience has also shown that a practical exercise of a knowledge of this subject has a wider field of application than could have been shown at an earlier stage of the investigation.

So essential, therefore, does the subject appear to be to a proper understanding of many local and more general disturbances, that a statement of the present stage of its evolution is proper and necessary.

In order to make as nearly as practicable a concise and connected exposition of the topic, I shall take the liberty of repeating, to some extent, matters which I have already published. It is by no means the purpose here to make simply a restatement of what I have already written; I propose, rather, to make a new statement of a subject which has been rapidly developed on important lines and has assumed added significance since my former communications.

DEFINITION.—To those who have not followed the previous discussions of the subject a definition will be necessary at the outset. By "normal declinations of the retinal meridians" is meant a deviation of the vertical, horizontal, or any given meridian of the eye from the corresponding meridian of external space when the line of regard of the eye is directed parallel to the median plane and in the horizontal plane, the head being exactly erect or, more technically, in the primary position.

To make the definition less technical, the following diagram may be of service.

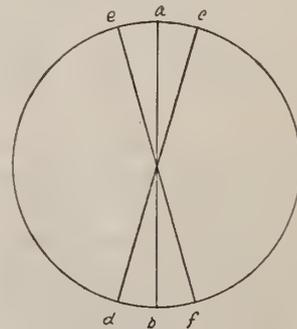

FIG. 1.

Suppose the circle *cae, fbd* to represent the equator of the eyeball, and the line *ab* to represent the normal position of the vertical meridian of the eye, the line of regard being directed as stated. If this line corresponds with the vertical meridian of surrounding space, there is no declination of it and consequently none of any meridian.*

*But Helmholtz believed that the horizontal meridian might be coincident with the horizon, while the vertical meridian was only an "apparent" one and deviated.

But, should the eye be rolled upon its anteroposterior axis so that this vertical meridian would correspond with the position *cd* or *ef*, it is evident that in either case the vertical meridian—and all other meridians—of the eye would no longer correspond in position with meridians of the same name in surrounding space. In either case there would result what I have called a *declination*. If in such a case the top of the meridian line *cd* leans toward the temple, it is termed a *positive (+)* declination, while if the line *ef* leans toward the nose, it represents a *negative (-)* declination.

There are normal declinations and declinations from disease or injury. It is therefore necessary to know what a normal declination is not. It is not the tilting of the meridians which results from any paralysis, paresis, or insufficiency of any eye muscle or set of muscles. In other words, it is not a disease. It is a normal, though unfavorable, condition. It should be called an *anomalous* in contradistinction to a *pathological* declination. And, since anomalous declinations are frequent and pathological declinations are rare, the term "declination" when used alone should apply to the first class only, while to designate the tiltings from disease or injury the limiting term "pathological" should be added. Nor should the term "declination" be confounded with the term *torsion*, which has been applied to the rotations of the meridians when the eye passes from the primary and horizontal position to some position in which the line of regard is directed to some point not in the primary position or horizontal plane.

These anomalous positions of the meridians are extremely common and are found in as many different classes of persons as are the anomalous refractive conditions of the eyes.

It is too early to state technically the precise physical conditions on which declinations depend. As a general statement, it may be said that they are peculiarities which are, doubtless often if not always, dependent upon the special conformation of the orbit in the individual case.

INSTRUMENTS FOR DETERMINING DECLINATIONS.—

The crude, indefinite, and inaccurate methods which were in vogue for determining the approximate directions of the tiltings of images in cases of paralysis or injury of the eye muscles previous to the introduction of the clinoscope find no place in the examinations necessary to a correct determination and evaluation of normal declinations.

The visual act must be confined to the test line alone, and all view of objects outside the tubes of the instrument must be excluded, in order that the eyes may be free from the instinctive, or automatic, effort to adjust themselves with reference to the position of external objects. The lines of sight of the two eyes must be absolutely in the same horizontal plane, and these sight lines are to be neither in convergence nor divergence, except to meet certain special contingencies.

These and other important conditions are met in the use of the clinoscope.

The clinoscope (Fig. 2) is composed essentially of two hollow tubes, each of which has at one end a minute pinhole opening through which the eye can look, and at the other end a translucent disc on which is drawn a line,

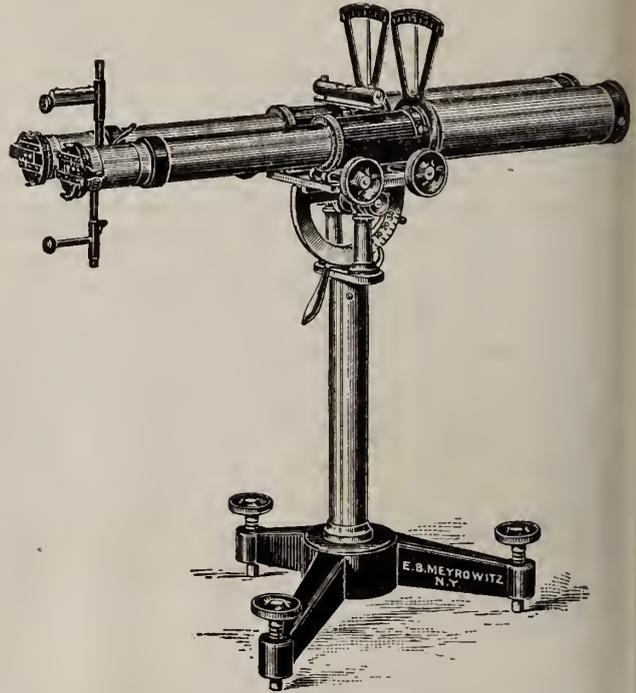

FIG. 2.—The clinoscope.

in the case of one tube from the centre straight up, and in that of the other tube straight down.

These tubes are so adjusted on a standard that they can be placed and maintained in the same horizontal

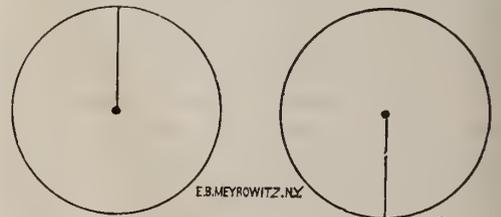

FIG. 3.—Objective lines of the clinoscope.*

plane, which is indicated by a spirit level, but from end to end they can be directed horizontally or up or down. They can, as above intimated, be made to converge or diverge to meet certain contingencies.

The tubes rotate on their long axes, and a pointer is attached to each tube indicates on a scale the extent to which the tube is rotated. The small sight openings are so adjustable that the distance between them may be suited to the interpupillary distance of different persons. For the accommodation of those who, on account of presbyopia, myopia, or any high degree of refractive error

*For purposes of physiological research objective diagrams of many designs may be connected with the clinoscope, but for practical purposes the above is sufficient, and it is important not to disarrange the working objectives.

cannot see at the distance of the test objects from the eyes, there are clips in which refracting glasses may be placed. The sight openings being very small and exactly in the same horizontal plane, there can be no doubt as to the erect position of the median plane of the head when the two eyes are seeing, each through its appropriate sight opening, any existing hyperphoria being corrected.

Any device for testing declination which does not provide for the exclusion of surrounding objects from the field of view and which does not also secure an absolutely erect position of the head is worse than worthless, since it must be misleading.

To meet the exigencies of cases of greater or less degrees of amblyopia, as in squint or extreme myopia, it was found necessary to devise what I have called the "lens clinoscope," an indispensable instrument, but one which cannot take the place, in ordinary cases, of the clinoscope.

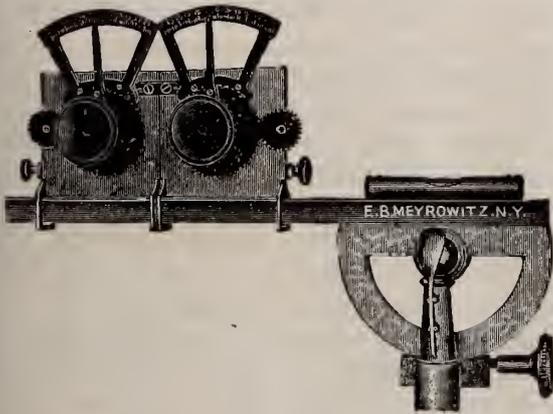

FIG. 4.—The lens clinoscope.

METHOD OF USING THE CLINOSCOPE.—The instrument is to be so adjusted in respect to height that the sight-holes will be on a level with the eyes of the examined person when sitting erect. This is best accomplished by the use of an adjustable table. The tubes may be exactly parallel or they may, in certain cases, be made to converge very slightly, thus making the distant point at 8 or 10 feet instead of infinite distance. Under other exceptional circumstances they may be made to diverge. The tubes must be brought to an exact level with each other as shown by the spirit level.

Unless the subject of the examination is unable to see the test lines of the tubes, on account of presbyopia or high refractive error, no glasses should be used, and when glasses are necessary the weakest that will enable the person to see the lines clearly should be placed in the clips. A prism for the correction of hyperphoria may also be required. *The glasses should not be worn*, since, if a strong glass should not be held exactly at a right angle with the axis of the tube, the lens would itself induce a declination of the image.

The examiner must be sure that the examined person sees through both openings simultaneously and that the view of both images is maintained throughout the examination, otherwise there can be no certainty that the head is precisely erect.

When the examined person has secured a good view of both the test lines he should endeavor, if they do not at once unite, to induce them to do so as in a stereoscope. Some people do not succeed in this, in which cases the examination may go on with the images separated, but it is less satisfactory.

When the apparent vertical position of the lines has been attained, the examiner should move them more or less backward and forward, in order that the true position may be more positively located. Few people can arrive at a satisfactory conclusion regarding the position of the lines at the first trial, but after a day or two the tests become, for nearly all intelligent people, remarkably uniform.

RESULTS OF EXAMINATIONS.—Previous to the investigations by the clinoscope a belief had prevailed among physiologists that there was, in healthy eyes, a fixed and definite position for the meridians of the eye, and that this position was general, if not universal. Helmholtz, Donders, Volkman, Meissner, and others had devised means for the investigation of the facts, all of which means were imperfect and misleading, and most of these investigators agreed that normally there existed, for the vertical meridian, a leaning out of about $1\frac{1}{4}^{\circ}$, while the horizontal meridian was supposed to coincide exactly with the real horizon.

One of the first results of the investigations by the clinoscope was the demonstration that the positions of the vertical and horizontal meridians leaned, when either leaned, in corresponding directions and to an equal extent. What was of far greater importance, it was found that the leanings of the meridians were as varied and as characteristic of the individual as the refraction of the eyes.

The clinoscope shows that in some persons the vertical meridian of one eye corresponds with an exact vertical line, while that of the other eye leans from one degree to many degrees. In other cases the vertical meridian of each eye leans in the same direction, that is, each to the right or each to the left, and this leaning is nearly equal in the two eyes. In still other cases the meridians lean in opposite directions, that of one eye to the right, that of the other eye to the left. In extent there is great variation, some cases showing the meridian of each eye very nearly erect, while others will show the meridians in both eyes leaning as much as six or even ten degrees.

It is these leanings which I have called declinations. They are not, as has already been said, *torsions*, which term has a well-established meaning, the phenomena to which it refers being widely different from those under discussion. Torsion results from an active adjustment of the eye and corresponds to the position to which the eye is moved. Declinations, on the other hand, are purely passive states to be determined when the lines of regard are fixed in the primary position.

In normally healthy eyes the leaning of a meridian may vary according to the automatic tension which may

be exerted. Hence it is found that very high degrees of declination are more frequently manifest in persons who have passed fifty years of age than in those who are younger. Hence also there is sometimes a variation which appears to depend on the physical condition of an individual at different times.

I have compared these anomalies of declination to those of refraction. As there are few eyes without some error of refraction, so there are few in which the insertions of the muscles are so ideal that there is no declination; and, as slight refractive errors may be disregarded, so slight declinations may have little practical significance. Even high degrees of declination seem in certain instances, like certain cases of high-grade hypermetropia, to exert no appreciable injurious influence. Yet, as a rule, as in refraction, the higher the grade of the anomaly the greater the resulting nervous disturbance.

SOME OF THE RELATIONS BETWEEN DECLINATIONS AND HETEROPHORIA.—Long before the principles of declination were recognized I became impressed with the belief that many of the phenomena of heterophoria and heterotropia were secondary to some other condition than the condition which was most manifest. Thus, for several years I had often expressed in my writings the thought that there were few, if any, cases of original exophoria, and I diligently endeavored to learn the true nature of the anomaly. Certain cases, too, of hyperphoria seemed to me not to be essentially such, and many cases of esophoria were so contradictory in their phenomena that there seemed to be demanded a further element to account for them.

The clinoscope has thrown a remarkable light upon these questions. A few of them are answered with ease, since the relations between the revelations by the clinoscope and those of the phorometer appear to be quite simple. In other cases these relations are much more complicated, yet, in general quite susceptible of explanation.

The relationship between declination and exophoria is perhaps the most easy to comprehend, and a study of these relations is most interesting. In exophoria there is, as a rule, positive (+) declination of both eyes, and the extent is nearly equal in each. The exceptions to this rule are rare, and even these apparent exceptions are, after close investigation, usually found not to be exceptions at all. On the other hand, positive (+) declination of both eyes is strongly suggestive of exophoria.

In the rotation of the eyes upon their long axes, in the effort to effect parallelism of the vertical meridians, each eye is forced downward and outward. The downward movements, if they are equal, have little influence in inducing heterophoria, but when the declination to be corrected is considerable, the effect upon the outward swing of the eyes may be very considerable. As each line of regard is forced outward the parallelism of the lines of regard is sacrificed to that of the vertical meridians and exophoria results.

It will be seen also that, if the leanings of the meridians are each positive but unequal, one eye would be forced outward and downward more than the other, and hyperphoria would result. These theoretical views of the adjustments correspond exactly with the results of practical experience when the phorometer and the clinoscope are used together. The manifestations of heterophoria are not always present when the inducing causes exist.

When operating for exophoria by slight tenotomies before the use of the clinoscope, I observed that, as a rule, the tendon of the externus was rarely, if ever, found tense. It was hard to believe that the exophoria could be the result of the predominance of force of this muscle, which was so often found much relaxed. Later, when the tropometer was brought to the attempted solution of these questions, it was found that there was, in most cases, no excess of rotating power in the externi or any deficiency of rotating ability in the interni. It was noticeable also that it was no uncommon thing that what was apparently a successful correction of the exophoria was only a temporary one, and that the defect was apt to return in a few weeks or even after a few days in almost as high degree as before the operation. It was in many cases deemed better to leave uncorrected a marked degree of exophoria than to reduce the rotating ability of the externi, either by tenotomy or by a contraction of the interni, to an extent sufficient to permanently abolish the exophoria. With the advent of the clinoscope much light was thrown upon this whole subject. With a knowledge of the declinations and their effects we may now look for a relief from exophoria without restricting the action of any muscle and with a reasonable expectation of permanency of result.

The hyperphoria which may result when there is somewhat unequal leaning of the meridians in the two eyes has been referred to above. In many cases of hyperphoria a declination of several degrees may be found for one eye while the other will be either without declination or with very much less than the first and usually of the same sign. An example of this will not be out of place here.

In a case of long-standing vertical diplopia there was, during four successive days' testings: Right hypertropia 10° in the primary position with increased hypertropia looking down 30° or up 20° . In alternate exclusion the deviation appeared even greater than that shown by the phorometer. The rotation up, as shown by the tropometer was, for the right eye 40° and for the left 36° . It would seem that this was preeminently a case for a tenotomy of the superior rectus of the right eye. Yet, as there was declination (-) 6° of the left eye and only (+) 1° of the right, I determined to do an operation on the *internus* of the left eye with only the declination in view, for there was no marked exophoria or esophoria. The operation was successful in correcting the declination to within 2° , and on the following day I had the satisfaction of finding that there was easy single vision with less than

2° hyperphoria and with no esophoria or exophoria. Although many weeks have passed since this operation, the hypertropia has not again manifested itself.

Such a case is of much interest in illustrating the dominating influence of declination even in extreme hypertropia. It is also interesting as an illustration of the daily experience in removing the conditions of heterophoria and even strabismus by the simple correction of declination. The example also shows how even the upward rotation may be influenced by the declination, for after the operation on the internus the upward rotation of the two eyes was nearly equal.

In esophoria declination is almost uniformly found in both eyes, and the leanings of the meridians are homonymous. If the declination is plus for the right eye, it is minus for the left, and most frequently the leanings are approximately of the same extent. The greater the extent of declination, usually, the greater the degree of esophoria.

Thus it appears that the different forms of heterophoria are associated with different forms of declination, and experience has shown that in a large proportion of cases a relief to the declination is followed at once by a relief to the heterophoria. In certain unusual cases it will be found that each eye will rise many degrees when a screen is placed before it. Even when any excess of upward rotation has been corrected the phenomenon remains. Here the upward turning is due to the declinations of the opposite eye and it will remain even after the eyes are both too low, unless the declination is corrected.

HETEROTROPIA OR STRABISMUS AND DECLINATION.

—The principles which apply to the relations between heterophoria and declinations apply also to strabismus. The conditions differ in respect to the degree of declinations and also, in general, in respect to the vertical rotations. The causative conditions of heterotropia are usually, not only exaggerations of those of heterophoria, but the conditions are also more complicated.

After some experience in the use of the tropometer I found that in nearly every case of converging strabismus there was not only excessive upward rotation of the eyes, but that this rotation was, in fact, in most cases extravagant. For example, instead of a rotation up of about 33°, which investigation and experience had shown was the most favorable, in cases of converging strabismus it was not uncommon to find the upward rotation as much as 50° or even 55°. A reduction of this excessive upward rotation, this anophoria, served, in a number of cases of marked squint, to relieve the defect without interference with the laterally acting muscles, and there seemed to have been found a condition a modification of which promised a relief in strabismus without an unfavorable restriction in the action of any muscle. A larger experience showed that, while there was in this thought an important truth, there remained an element of uncertainty with respect to results which was of great practical importance.

With the introduction of the clinoscope new observations were made, and it was soon found that in nearly all cases in which there was a very excessive range of rotations in the vertical direction there were also unusual degrees of declinations. Applying these new facts to those which had been previously observed, there arose the reasonable hypothesis that the excessive declinations combined their influence with the excessive vertical rotations to induce the strabismus.

Close observation and added experience have confirmed this hypothesis, which, in the light of abundant practical facts, has now become a demonstrated proposition. It will be seen as we proceed that it supplies a rational method for the cure of converging or diverging strabismus without the disability which has invariably resulted to the tenotomized (or contracted) muscles in the older methods of operating for squint.

It may be said that, as a rule, there is in convergent squint excessive upward rotation with extreme homonymous declination, that is, with positive declination for one eye and negative for the other, or, rarely, the declination for both may be of one sign but differing greatly in degree. In some of the cases of the latter class there is alternating squint. If the eye with the extreme positive declination is fixed upon the object, there will be converging squint, while when that with the less declination is in fixation a divergence occurs.

If also, as it sometimes happens, there is little or no declination for one eye with great declination for the other, we have the important elements of intermittent strabismus. If the eye with little or no declination is in fixation, there may be no deviation of the eyes, but if that with the extreme declination is the fixing eye, strabismus occurs.

We have thus for the first time a logical and a uniformly applicable explanation for all the various forms of so-called concomitant strabismus. With a good understanding of the principles of rotation and of declination there is no longer a necessity for a new theory for each form of strabismus.

Without entering upon the details of all the elements inducing diverging squint, it may be stated that there will be found the same class of declinations in exotropia as are found in exophoria, but in high degrees. So in hypertropia the conditions are similar to those of hyperphoria, but, as in the cases of esotropia and exotropia, these conditions are extreme and usually combined with anomalies of the vertical rotations.

LOCAL SYMPTOMS OF DECLINATIONS.—Many of the symptoms of declinations are similar to or the same as those which are attributed to heterophoria. But since the study of the former class of anomalies has placed the whole subject of heterophoria in a new light a considerable number of the symptoms which appeared to result from heterophoria can now be directly associated with the definite disturbing cause as it was not possible to do before.

One of the most common and persistent of the local symptoms is dryness of the eyelids with smarting of the eyes and a sensation of grit in them. The chronic hyperæmia of the lids which is so annoying to many patients and so difficult to cure is in most cases the direct result of the pressure of the lids against the eyeball, a pressure exerted to hold the eyes steady in resisting the tendency to roll incident to the inclination of the meridians. The hyperæmia disappears without direct treatment when the declination is corrected. I have elsewhere* shown the importance of the condition of anophoria as an ætiological element of trachoma, and this condition is the more important in its ætiological effects in proportion as it is complicated with pronounced leanings of the meridians.

Another symptom, less local, is the habitual pain in and over the brow of one eye or those of both eyes. If the brows are carefully observed, it does not require minute inspection to see that one or both brows are strongly arched, or that one brow is flattened against the eye while the other is arched. Above the arching brow there are to be seen in many cases folds in the skin showing the tension of muscles beneath.

The pain above the brow in these cases is not a reflex disturbance, but the immediate and legitimate suffering of the muscles acting to elevate or depress the brow. This is shown when the declination is relieved, for the brows then at once assume a gentle curve and the pain vanishes in a day.

(To be concluded.)

A STUDY OF BUBOES AND THEIR TREATMENT.

BY FREDERIC GRIFFITH, M. D.,

NEW YORK,

SURGEON TO THE BELLEVUE DISPENSARY.

IN speaking of a bubo, an inflammatory condition of one or more of the inguinal lymphatic glands, with or without involvement of the adjacent cellular tissues, is implied in this article, with an especial reference in diagnosis and treatment to chancroid as a cause.

The superficial fascia made up of loose areolar tissue is, in the groin space, divisible into two distinct layers, between which are found from six to ten or more lymphatic glands arranged; the "horizontal series" along Poupart's ligament, and the "vertical series" along the internal saphenous vein. The deep glands, about four in number, situate in the crural canal along the course of the femoral vein, are connected with the superficial glands by means of lymphatic vessels running through the saphenous opening. Each gland is made up of a number of lymphatic nodules (oval masses of adenoid tissue) surrounded by a delicate membrane, forming, by the partial fusion of the nodes, trabeculæ of connective tissue, the whole bound together and enveloped by a capsule of

fibrous tissue, amongst whose fibres in the larger glands are found bundles of involuntary muscle. The presence of muscle fibre and the inherent property of elasticity in the gland explains the power of extreme distensibility possessed by it. Opposite the most convex surface, the capsule dips deeply into the substance of the gland, forming the hilum. Here enter blood-vessels and nerves for its nutrition. Glands have comparatively large arteries and yet larger veins supplying them, all intimately connected by cellular tissue.

Joining with each lymphatic gland and forming an intersecting system of canals, peculiar in that, in anastomosing, the vessels do not unite to form larger trunks, but keep the same size after union as before, are the lymphatic vessels. These lymphatic vessels, which go to make up the great lymphatic system, are characterized by the great number of valves which they contain. The vessels running to the gland (afferent) enter with additional blood-vessels at points over the surface of the capsule and open into channels between the masses of adenoid tissue and the framework (trabeculæ), forming lymph sinuses. Lymph sinuses reform at the hilum into the outgoing (efferent) vessels. Every lymphatic gland is an organ, having, as we have seen, each its own blood supply and a nerve supply with functions to perform, one of the most important of which is to act as a filter. An abrasion or traumatism of the skin with the introduction of some form of pus organism will call this function into action.

The superficial lymphatic vessels from the scrotum, penis, labia majora and perinæum, terminate in the upper, or horizontal, series of glands. Thus, chancroids located on the penis, an infected wound on the prepuce or the penis, cancer of the scrotum, abscess in the perinæum, or any infection of the integument or superficial structures of these parts, will cause enlargement of this set of glands; whereas, any infection taking place on the lower extremity will involve the lower, or vertical, series of glands. This distinction is only of secondary importance, however, as the sets of glands have so many routes of intercommunication that no positive diagnosis should be made until the source of the infection has been found. The lymphatic vessels, the feeders to the glands, are in turn derived from networks of finer collecting lymphatic capillaries. The superficial lymphatic vessels of the penis commence in a plexiform network of lymph-spaces found in the corium and the papillæ of the skin; also from about the hair follicles and sebaceous glands. Thus we have an explanation of the formation of a chancroid without there having been any maceration or break in the skin, absorption having taken place directly through lymph spaces connected with a hair follicle or a sebaceous gland. This is further explained when, in addition, if the sore be on the glans or inner side of the prepuce, we have uncleanly habits associated with a tight foreskin, having thus at once two of the cardinal conditions for germ development, heat and moisture, and lacking only the one most easily supplied, the presence of the inoculat-

*Proceedings of the British Medical Association, 1897. *Ophthalmic Review*, September, 1897.

ing pus organisms. The superficial lymphatic vessels of the penis, with which we are most concerned, are divisible into three sets, those from the skin covering the glans end in a vessel which runs along the dorsum of the organ to the pubis. The vessels from the rest of the penis unite to form (one on either side) two vessels which join with the dorsal to form a short common trunk at the pubis, which almost at once divides again into two vessels, one going to the right, the other to the left group of inguinal glands. Thus we can understand why at times a sore on one side will give rise to a bubo on the opposite side; or, the site of the sore being on the dorsum of the glans or in the sulcus, it gives rise to a bubo on one or the other side, or more rarely both sides. The rule is for the bubo to be on the side on which the sore is found, but the arrangement of the lymphatic vessels before uniting with the glands will explain this diversity.

Buboes may be classified according to the source from which they have sprung as: 1. Simple inflammatory bubo; *a.* Bubon d'emblée; *b.* Gonorrhœal; *c.* Balanitic; *d.* Herpetic; 2. Chancroidal (true bubo); 3. Syphilitic; 4. Bubonocele; 5. Tuberculous; 6. Cancerous; 7. Plague.

1. *Simple inflammatory bubo.*—That produced by pyogenic infection somewhere about the lower extremity, more often about the foot or toes, as the infection resulting from ulcerating tissue about an ingrowing toe nail.

Under this head Dr. Nagel, an English naval surgeon, describes what he calls provisionally a "climatic bubo," which he encountered along the east coast of Africa. It is not of malarial origin, he says, as quinine has no effect upon it; and, in an epidemic which broke out on his ship while in these waters, though no landings had been made, of one hundred and twenty-three cases, in no instance did the temperature rise above 102.2° F. and but few suppurated.

a. Bubon d'emblée, due to traumatism. False bubo, so-called, of the older writers, who stated that a bubo might develop without any initial lesion. Under this head may be placed an inguinal adenitis which might arise from injury during coitus, or that following the passage of a sound or other urethral instrument.

b. Gonorrhœal bubo, here usually of pyogenic origin secondary to the gonorrhœa.

c. Balanitic bubo, secondary to the infection on the glans penis.

d. Herpetic bubo, of like origin following the herpetic ulceration.

2. *Chancroidal (true bubo).*—The absorption of the products of the virulent mixed forms of pus micro-organisms, which gives rise to this form of bubo, constitutes what in the general acceptance of the term is meant when bubo is described in genito-urinary work.

3. *Syphilitic bubo,* due to the specific virus. Buboes arising from the mixed infection of syphilis and chancroid, partake of the nature of each as when found alone.

4. *Bubonocele,* a term referring to any lump in the groin, or, more particularly, a small or beginning in-

guinal hernia where but a portion of the mesentery or omental fat only is presenting.

5. *Tuberculous bubo,* caused by the reaction of the gland to the tubercle bacilli.

6. *Cancerous bubo,* due to extension from cancer foci from a near-by part, as cancer scroti.

7. *Plague buboes* may be merely mentioned, as they are only of importance in this relation where the question of diagnosis arises.

Pathology.—The reaction of lymphatic vessels and glands to micro-organisms is characterized by an outpouring of leucocytes, lymphocytes, and round cells, with proliferation from the endothelial lining of the gland vessels. The infected gland becomes juicy, red and enlarged, with capillary hæmorrhages scattered through it, especially about the periphery; then, if resolution sets in, absorption takes place of the products of inflammation, the gland becomes pale from pressure on the blood-vessels, then again becomes red (splenified) from secondary congestion after removal of inflammatory exudate, and gradually returns to its normal appearance. If degeneration takes place, which is usually by suppuration, the gland becomes filled with minute yellowish points that first cause the gland to harden, and later, to liquefy; and the contents, breaking out through the capsule, infect the surrounding cellular tissue and become an abscess which, breaking externally, leaves a granulating tract. Where the infection is more virulent, as from a chancroid, there is at times a simultaneous reaction in the cellular tissue, and the whole becomes rapidly glued to the skin and the superficial fascia, with a consequent increase in the inflammatory reaction and rapid abscess formation. The cellular tissue at times liquefies first, leaving the gland mass. If it is allowed to open by pointing or by incision ulcerating sinus tracts are left which show little tendency to heal. If syphilis is the cause, the gland hypertrophies, taking on an increase of leucocytes and lymphocytes, but the main feature is the fibroid change (induration), so called, which takes place by an overgrowth of the connective tissue elements in the trabeculæ, or framework, of the gland. Suppuration rarely takes place. There is always a vestige of induration with some hypertrophy of the gland. Tuberculous degeneration, here as elsewhere, is the same. First, the deposit of tubercle bacilli giving rise to irritation, formation of giant cells, and infiltration. Secondly, coagulation necrosis giving rise to the gray tubercle. Thirdly, liquefaction necrosis causing yellow tubercle. Fourthly, the continued action of the bacilli causes the change into the puriform mass, which becomes pus (mixed infection) when pyogenic organisms gain entrance. Cancerous infiltration is most often secondary to cancer of the penis or scrotum. The infiltration consists of an unlimited proliferation of the lining cells which become polymorphous and burst through into the connective tissue. Sarcoma rarely affects lymphatics. In plague, there is rapid infiltration and suppuration

of gland tissue, with specific bacilli and pus organisms found free.

Diagnosis.—The chaneroidal bubo comes on most often near the close of the third week of the infection from which it has developed, though it may appear with the chaneroid or at any time during its course. Puche has reported the development of a bubo three years after the original chaneroid. Here, I think, we have an example of an infected gland which lay dormant during the period stated, during which time no inflammatory reaction was noticeable. In the case of my own, the patient had had the year before a "sore," followed by a bubo, which, under treatment, aborted, leaving a small, painless "lump" in his groin. One month ago he contracted a chaneroid, and at the same time a bubo developed, or rather the already infected gland became an abscess, liquefying within the course of two weeks. The infected gland may sometimes be traced from the source of infection by a corded vessel (lymphangitis) directly. The patient will first be made aware of the oncoming infection by a slight, though increasing, restriction of full extension of the thigh (a developing bubo will be first made apparent by tenderness over the affected gland, and pain when the thigh is fully extended); or else he will feel a hardening lump about the size of a small chestnut, freely movable under the fingers and slightly tender to the touch. Usually within the course of a week it will be fully developed as a hot, dusky red, painful, somewhat irregular, caked, tumor-like mass in the groin, varying in size from a pigeon's to a goose's egg. When fully developed, softening of the mass takes place, and the skin covering it becomes mottled and livid, oftentimes scaling. The tenderness becomes a throbbing pain, and fluctuation and suppuration with discharge through one or several openings prove the presence of an abscess. The pain of a developing bubo varies; it is often very severe and of a sharp, lancinating character; it will suddenly cease, which is explained by the rupture of an over-distended, infected gland capsule.

Associated with the formation of pus in a ripe bubo are the constitutional symptoms of fever, usually but moderate in degree. As a rule, the patient will not take to his bed, though, by restricted movement, he will protect and ease the bubo as much as possible. Turning back the foreskin, on the dorsum of the glans penis, in the sulcus back of the corona, or about the frenum will most generally be found the source of the bubo, as a chaneroidal sore rapidly healing or extending.

The number of sores and the condition in which they are seem to have no effect on the presence or course of a bubo. Oftentimes the patient will be unaware of the presence of the sore.

In a case I have seen, in which the patient applied for treatment for "gonorrhœa" in addition to his bubo, he explained that, in spite of the discharge which had lasted for a week, he was suffering from no pain on urination. On exposing the glans, which he had not done for some

time previously, I discovered a chaneroid in the sulcus which was freely discharging. The urethra was normal. The chaneroid may be on the foreskin, on the body of the penis, on the scrotum, or at the penoscrotal junction. Two cases in which I believed the sores to be primary chaneroids about the anus in subjects whom, from the history, the total ignorance of the patients (who arouse my suspicion by their extreme innocence), and the relaxation of the anus (conical), I considered sexual perverts I was unable to study carefully; as in one instance the patient appeared but twice, the other patient I saw but once.

This bubo is usually monoganglionic, but one gland being involved, unilateral, and is on the same side as the one on which the sore is found. Chaneroidal buboes, though they at times abort, tend to abscess formation.

Syphilitic buboes are bilateral and are made up of one or several glands, grouped together or in a chain of three or four (polyganglionic). They may come on from a few days to three or four weeks after induration of the primary sore has taken place. There is little or no involvement of the subcutaneous areolar tissue. They are freely movable under the skin, not painful to the touch and show but a moderate degree of swelling. The tendency is toward resolution, though there is always a vestige of induration with some hypertrophy of the gland making up the bubo. Under specific treatment, much decrease in size takes place. It has been stated that when all induration of the glands has passed away the patient may be on exposure reinfected with syphilis.

Chaneroidal bubo may be diagnosticated from simple inflammatory bubo, bubon d'émblée, gonorrhœal, balanitic or herpetic bubo, by the history of a traumatism or an infected wound of the lower extremity. In simple inflammatory bubo the rapid development of the bubo within the course of two or three days, with an associated inflammation at times of the lymphatic vessels from the point of infection (lymphangitis), demonstrated as a tender red line, will serve for diagnosis. Bubon d'émblée is to be recognized by the mildness and absence of positive history. A gonorrhœal bubo may be inferred when after close examination, neither chaneroid nor herpetic sores are found, nor balanitic inflammation associated with the urethral discharges.

If a phimosis exists, a positive diagnosis as to the nature of the concealed trouble cannot be made.

The diagnosis of bubo from hernia or bubonocèle is made from the history and from the fact that reduction and disappearance are made possible by manipulation. Tuberculous bubo, a cold or psoas abscess, can be recognized from a chaneroidal bubo by the history of the course of the disease and the accompanying tuberculous diathesis. Cancerous bubo is diagnosticated by the history, the stony hardness of the growth when palpated, and the irregular outline due to involvement of the lymphatic vessels as well as the glands. In plague, the history will aid in determining the diagnosis.

Undescended testicle retained in the canal, with an accompanying inflammation, may simulate a bubo, but the absence of the testicle on that side will clear the diagnosis at once. A varix of the saphenous vein as it comes from the crural canal may be mistaken for bubo of the groin. The presence of other varicosities, and the fact that by pressure the tumor disappears and refills when released from below, will aid in diagnosing its true nature.

Aneurysm of the common femoral artery as it comes out from under Poupart's ligament may be mistaken for chancroidal bubo, as in a case I have seen in the person of a colored man, aged forty-three years, who applied for treatment for a sarcomatous growth on the opposite femur. On examining him, a lumpy tumor of the size of half a small orange was to be felt which could be squeezed flat like an atomizer bulb. The blood column being pushed out, returned after two or three pulsations. The man said that he had "had that lump for twelve years" without any change. A bubo had been diagnosed and opening advised on a previous occasion.

Inflammation of the cord complicating gonorrhœa may simulate a bubo, but as it is rare for this to be present without an accompanying epididymitis, the diagnosis should be clear.

Until one has gained a reputation as a healer in matters venereal, the surgeon will find no class of patients who require greater tact in their management than these. On general principles a specific prescription should never be given to a genito-urinary patient.

Most of this class of patients have either been to another doctor or they have a friend who has "had the same disease," so the patient comes with notions of his own as to what is to be done. One patient who had contracted an uncomplicated, though extensive, chancroid, after two weeks of treatment with but slow improvement, was honest enough to tell me that he doubted the sincerity of my methods. He stated that he had on a previous occasion cured himself of a sore worse than this with caustic silver, in a few days, and that if I would use that it would get well. I gratified him, with the result that he left with a black eschar covering the site of the chancroid. He returned in two days penitent, and with the sore much inflamed from renewed infection having taken place under the crust which the silver had made. The class of young men, mostly clerks and those on weekly salaries, who become patients from these forms of disease, are such as can ill afford to give up work for a stay in bed, were it required, as is the case after open incision and free dissection or curetting of a bubo.

Treatment of a chancroidal bubo naturally implies treatment of the chancroid from which it sprang, as, while it lasts, it is a continual source of danger and may at any time give rise to renewed infection. The sore, thoroughly exposed, is first to be gently washed with warm water and castile soap, forming a lather as carefully as when shaving, using absorbent cotton to thoroughly

soften and remove, without causing bleeding, all scabs and discharge (a chancroid should never be allowed to crust over, otherwise, while apparently healing, the retained discharge will cause extension and rapid re-infection; then, with cotton swabs on toothpicks, the sore is to be thoroughly dried. With an atomizer, a strong spray of hydrogen dioxide is to be thoroughly applied directly to every interstice; if the foam becomes blood-tinged the spraying should be discontinued. The forcible application of this drug seems to give it greater value than when it is simply washed on. The foam is now to be mopped off and a thin wisp of cotton containing a few drops of the same drug is to be laid on the sore, then, with one steady movement, the retracted foreskin is to be drawn over the glans. The patient must be specially taught how to do this, otherwise the cotton which he applies will either roll up back of the corona or be pushed aside, leaving the chancroid entirely uncovered and giving rise to renewed infection on all sides. Cotton is better to use than gauze or lint; it is less bulky and irritating. As there is evidently some movement of the foreskin over the glans in walking (slight as this may be), the rough threads of the gauze or lint do not decrease the friction over an inflaming chancroid. Ordinary rolled cotton can be separated like the leaves of a pamphlet, and it is one of these thin, torn fragments that will cause the least friction and absorb equally well with a tuft. As half of the treatment of a chancroid lies in what the patient does while he is away from you, these minor instructions will serve a good end. Where a phimosis or infiltration prevents retraction of the foreskin, or if there is much pain, the penis may be given baths of hot water of five or ten minutes' duration, when possible, several times daily, by inserting the organ into a can of water as hot as can be borne. If, after repeated efforts, the phimosis cannot be overcome, the foreskin is to be laid open with the median incision as for the operation of circumcision. We must assume the risk in these cases of infection of our wound taking place. The patient is to be given an ounce or two of *lotio hydrargyri nigra* (black wash), of which, after each washing and thorough drying, he may apply a drop or two on cotton, leaving it in contact with the chancroid. As the object of treatment is to dry up the sore, too much of the wash must not be applied at one time, otherwise the virtue which lies in its slightly astringent action is lost by the maceration caused by too much moisture, from the saturation of the applied wisps of cotton. The cotton should be changed at least every two or three hours; the washings and applications night and morning will be sufficient, as it is important that the patient should take no washes or medicines to his work to excite suspicion as to his ailment. He should, also, be warned against talking about his disease. This applies to all genito-urinary diseases. In three instances in which I have neglected these warnings, I can now recall that patients have been discharged for having evidences of their disease about the shop.

At times I have found a sluggish sore do well under blue ointment (*unguentum hydrargyri*), applied daily as the wash was used. Under these modes of treatment improvement should become apparent and progressive within the first day or so, and only after a thorough trial should we turn to escharotics. Internal medication, aside from general hygienic treatment, and keeping the bowels freely open, as irritation may be increased by straining, is not often necessary, though it has been said, and I have found it to be the case, that iron as in the form of Blaud's pills or the elixir of iron, taken twice daily, or more often if need be, is oftentimes of value. As a bubo is, until pus formation takes place, a local affection, our aim in early treatment should be toward the prevention of this change by the employment of abortive measures. The application at bedtime of an ice bag, or of a towel wrung out in boiling water, or a flaxseed poultice (which last, after all, is not such a mass of septic organisms as many surgeons believe, since it is rendered sterile by the heat and boiling in the making), will, if carefully carried out with energetic treatment of the origin of the infection, allay the trouble in fully one-third of the cases.

A daily application of the following salve:

R	Unguenti hydrargyri,	}equal parts.
	Unguenti belladonnae,	
	Unguenti ichthyolis,	

M.

will often do good. I think it acts by lubricating and softening the skin and subcutaneous tissues. It should always be applied with a soft stroking movement, as rough handling will crush the already diseased gland tissue and hurry suppuration. The earlier a bubo comes on after the sore which caused it, the more likely it is to go on to abscess formation in spite of efforts to prevent. After the formation stage has become well advanced, instead of endeavoring to avert an abscess, we should direct our energies to hurry this result by continuing the fomentations as often and as hot as possible. Pain becoming unbearable, suppuration demonstrated by fluctuation, are alike the determining factors for active treatment. The indications are now the relief of tension and the withdrawal of septic matter. The question of whether or not the abscess contains micro-organisms is an open one. Martin states that repeated microscopic examinations of the contents of suppurating buboes have absolutely failed to show the presence of any micro-organisms, and, again, the evidence is strong, though not conclusive, that, in certain exceptional cases, not only the irritating products of the micro-organisms, but even these micro-organisms themselves are carried directly to the lymphatic gland. Be this as it may, the question of whether we have to deal with micro-organisms or toxins is but of secondary importance. After a thorough cleansing with warm water and castile soap, followed by shaving of the parts on the side affected, a guarded, keen-edged, curved bistoury is to be plunged into the swelling until all sense of resistance is

lost, or until the centre of the glandular mass is judged to have been reached. The site of puncture is denoted by the point of greatest tension, a pale area surrounded by deep purplish red coloration or one of darkest-colored hue. When the first gush of fluid has ceased, a blunt probe or a grooved director should be swept around the cavity and through the honey-combed tissues, thus opening up channels of exit. The amount of pain that this will cause will be readily borne by the patient, following so close on to the relief given by the opening. In cases where the puncture is made early for relief of pain only, and the infected gland will not discharge, five or ten drops of pure carbolic acid are to be injected through a hypodermic syringe into the centre of the gland or masses of hardened cellular tissue. Should the action be too great, alcohol, 95 per cent., will neutralize the effect if injected within a few minutes after the acid. A spray of ether or of ethyl chloride or a piece of salted ice wrapped about with a towel, may be used to anæsthetize the point of opening, though usually no anæsthetic will be required. I saw a rather ingenious method of anæsthesia applied for such a case in one of our hospitals by a resident physician. With a swab saturated with pure carbolic acid he made a sweep some two inches long for its anæsthetizing effect, following it with an incision of a scalpel. The writhings of the patient meanwhile proved to me the impracticability of the procedure. Finally, further loosened necrotic tissue should be removed by pressure gently but firmly made with a dossil of cotton or a piece of gauze held in each hand, a thorough syringing should be practised with hydrogen dioxide, pure or diluted with from one to four parts of water, according to the amount of pain caused. This should be followed by the insertion of a loosely twisted strip of rubber tissue, a wisp of horsehair, or a twist of catgut, to act as a drain. It has been stated that hydrogen dioxide causes renewed infection at times by its gases of decomposition forcing infected matter deeper into the spaces of the surrounding tissue. I have not found this to be the case in my own experience of the drug. If, however, this should occur, a simple dilution would remedy such action. The dressing is completed by dry, loose, sterile gauze and a snug spica of the groin. If the discharge is free, and, drying in the dressing, crusts and causes pain, it may be relieved by the patient himself pouring a portion of a cup of boiled water down in the inner dressing. This is, as often as not, unnecessary, and a better result will be obtained by keeping a dry dressing, by which a possible source of infection—viz., moisture—is removed. Only enough dressing is to be applied to absorb the discharge. Large dressings will keep the parts, especially in summertime, too heated, and macerate the tissues. Walking will do no harm; it rather helps by squeezing out the infiltrated tissues. The patient should be cautioned to exercise ordinary care when at work as to lifting or straining, however. Herniæ secondary to bubo operations are not common, however; puncture, with practically no resulting scar, will take

away this predisposing cause. The next dressing and washing out with hydrogen dioxide should be done in twenty-four hours. Nothing will drain pus perfectly. If we had any perfect method of drainage, it would never be necessary to wash out pus cavities. So-called drains act after the first capillary ooze has ceased by keeping the aperture open. Perfect drainage is obtained when the abscess cavity is washed out sufficiently often to induce continuous contraction and the cavity has not time to re-fill. Dressings at intervals of from two to four days thereafter should be made. The hygiene of the patient should be looked after; alcohol, fried, greasy, and indigestible foods are to be avoided. The bowels should be kept loose by teaspoonful doses of Epsom salts taken every other evening.

Sometimes a bubo will remain stationary at some early stage of development; it may then be treated actively by fomentations and poultices while the chancroid is healing. But when the sore is well, stimulation of the bubo should cease, as very often it will cause no further trouble; the patient is to be advised that, if it should ever through injury give rise to abscess formation, it can be readily removed at that time.

The advantages of the treatment for buboes which I have described, are twofold. The patient is not forced to bed and the time of total treatment is appreciably shortened. I have seen buboes incised, curetted, and dissected out totally, the wound, varying from three to five inches, closed only to see the total area again break out as one sore, taking six or eight months to heal, besides the two weeks in bed required after the operation.

An average case by puncture is as follows:

W., aged twenty-five years, single. A chancroid on the corona centrally situated, incubation of seven days. During the third week the sore healed rapidly; meanwhile a bubo developed on the right side, and was punctured on the tenth day and treated as described, with an entire cure in one month and four days.

A case of simple bubo from traumatism was in a patient in whom, on examination, I found a left-sided bubo well developed, and a healed sore on the outer (left) side of the foreskin. I removed the scab, a thick crust, from the site of the sore, but found no infection beneath it. It had about healed, and became perfectly glazed over during the following few days. The patient informed me that the sore had followed the scratch of a nail while he was climbing on to a raft while bathing some three weeks before. The bubo which followed formed rapidly and was fluctuating, though deeply seated when I saw it. The patient called for the relief of his pain. The pain was cured instantly, and the abscess entirely healed in twenty-one days from the time of puncture.

An uncommon case I consider the following:

C., aged twenty-one years, three chancroids on the glans, not actively discharging. A bubo developed during the month on the right side, two sets of glands being involved, which I reached by two punctures within the time of total treatment, notably seven months and a week.

The patient, however, never lost a day, nor did he ever suffer much discomfort. After eighteen months, and a suspicious connection, he called to see if he was reinfecting or if there was danger of the "old trouble coming back" at the site of the former infection. I found the small puncture scars not noticeable, no indurated glands were felt, and the skin scar was not bound down to the subcutaneous tissues. After two visits he was willing to be discharged, still cured.

In such a case as this, if dissection had been practised, general anæsthesia would certainly have been required, which in itself is a detriment.

In another case in which I operated a year ago, the patient returned to ask if an acne eruption on his face was not a sign of "it" (syphilis, I suppose, he meant) "getting in his blood." In two weeks I relieved his mind on this score.

Between these limits, inclining mostly toward the former, will the period of time required for treatment be found to lie. The treatment of puncture for buboes was first suggested to me by Dr. Edward Martin, while I was working in his clinic in Philadelphia; but very lately, in reviewing some of the literature on the subject, I found in a lucid article by Auspitz that he was the author of a mode of treatment as follows: As soon as he can feel and grasp the hardened gland, he presses it between the thumb and forefinger of the left hand toward the skin, then with a sharp, narrow bistoury he penetrates the skin only, and following it with a blunt-pointed probe, he enters into the substance of the gland; then, with a prying motion in all directions, he tears up the connective tissue, causing but moderate pain. Usually but one tearing up is needed, though it may be repeated if necessary.

I cannot, therefore, present this method of treatment as wholly original, but simply give it my approval and trust that others will be as successful in what seems to be a rational mode of treatment as I have thus far been.

HYSTERICAL ANÆSTHESIA AND ANALGESIA.*

By B. C. LOVELAND, M. D.,

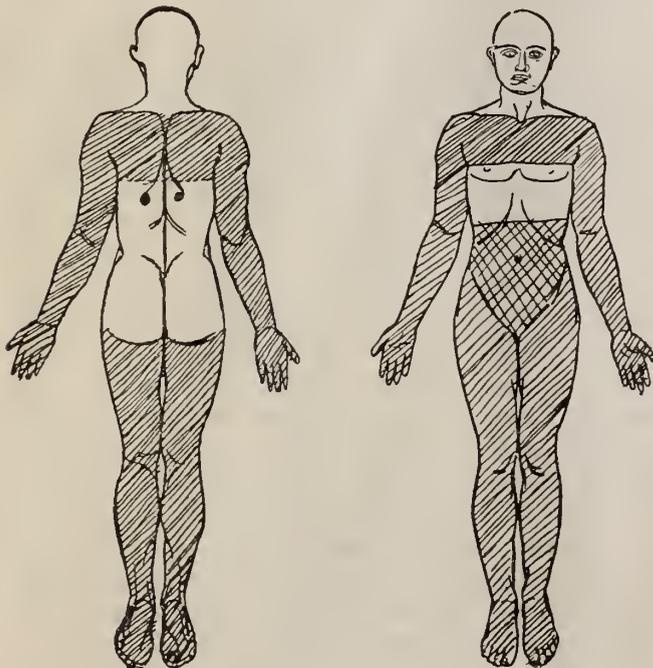

SYRACUSE, N. Y.

MISS M. M., twenty-four years of age, unmarried, came under my care on May 20, 1898. Her menstruation, always irregular, began at fourteen, and usually recurred at intervals of about five weeks. She had typhoid fever at sixteen, and rheumatic fever at twenty-two years of age. Her heredity was good. She was subjected to a nervous shock two or three years before I saw her, on the death of her father, which occurred suddenly from apoplexy while she was alone with him in the house. She had also been under a nervous strain for some years by reason of an unsettled love affair, which was the subject of much difference of opinion on the part of various members of the family, and which she had finally set-

*Read before the Medical Society of the State of New York at its ninety-fifth annual meeting, held in Albany on January 29, 30, and 31, 1901.

tled by breaking off the engagement. This had occurred about three weeks before I saw her, and was followed by a severe hysterical crisis, in which, so the nurse who was with her said, she acted as if she had lost her reason and started to leave the house only partially clad, but was prevented. At my first interview she was unable to give a correct account of the past three weeks, but by the aid of the nurse I learned that she had been at first very much excited, sleepless, and wanted to get away from her friends, for she thought they had all turned against her. She also complained of numbness in her limbs, which was less noticeable after a few days. She never complained of *globus* except when faradism was applied to some spots on her back, which are described later as hysterogenic zones.

Her condition at the time of the first examination was as follows: Body generally well nourished, though muscularly weak; pulse 60, irregular; temperature normal;

The white areas show normal sensation, the diagonal shading shows total anæsthesia, the crossed shading indicates hyperæsthesia, and the black spots mark hysterogenic zones.

blood, hæmoglobin 100 per cent., red corpuscles 6,080,000; reflexes slow; pupils dilated, and such tenderness on pressure over the abdomen that an investigation of the abdominal organs was postponed. Later examination of the abdominal and pelvic organs showed them to be normal. A diagnosis of hysteria major was made, and after a few days my attention was called to a lack of sensation in her limbs by a masseuse who had made her black and blue while administering a treatment. The patient was, until this time, unaware of the anæsthesia. A map of her heat, pain, and tactile sense areas was made, which was as follows: Normal sensation over the head and neck: tactile, thermic, and pain anæsthesia from the collar bone to just above the nipples in front, and over an equal area on the back, both shoulders, arms, and hands being included in the anæsthetic area. On the front of the body, sensation was normal from the nipples down to a line across the body at the tenth ribs, where an area of extreme hyperæsthesia began and extended to the groins. On the back, normal sensation extended from the lower

angles of the scapulæ to the gluteal folds, except at two small points just below the scapulæ, which are shown in the diagram, and were extremely sensitive—in other words, were hysterogenic zones; electrical stimulation of these spots would immediately develop a hysterical attack. The limbs, including the feet, were void of all sensation of heat, cold, contact, pain, or location, a deep puncture with a large needle producing no evidence of feeling, the upper limit being the groin in front and the gluteal fold on the back. Contrary to what is usual in such cases, puncture with a surgical needle was followed by some blood and by ecchymosis, though the skin presented the usual pale appearance. All the lines between the sensitive and insensitive areas were very sharply defined, and there was no tapering off of sensitiveness.

In the course of recovery, sensation first returned in the palms of the hands and the fingers, then in the dorsal surface of the feet. There was a gradual extension of sensitiveness from the extremities toward the body, but there was not the frequent change in outline of the anæsthetic areas which so often marks the hysterical type. Electrical stimulation would produce contraction of any group of muscles, but at first the patient could not tell which limb was the subject of contraction unless she saw it move.

Before she left my care she passed through such a variety of nervous phases, some of which affected her so seriously, that a brief history of her case in its other aspects may be worth recording.

She was at first constipated and would go for days without an evacuation with no apparent discomfort, laxatives producing little result, when one night she developed hysterical convulsions in which the spasms were general, including double strabismus, which lasted for about two hours. After this attack she began to have diarrhœa, from five to eight evacuations daily, and also menstruated about every alternate four days. From this time, alternating diarrhœa and constipation, and frequent menstruation, continued for several months.

The treatment applied for the disorder of sensation was faradism, or the interrupted galvanic current of sufficient strength to contract the muscles, and strong mental suggestion. After a few such treatments sensation returned in her hands and in the dorsal surface of her feet, but was most acute in the fingers. Normal sensation was slow in returning, beginning in the extremities and gradually extending toward the body. When the anæsthesia was at its worst there was also considerable muscular weakness, so that at one time she had not enough grip in her hands to make a record on the dynamometer. During one of her spells of constipation she seemed to resist all remedies, and vomiting set in, which soon assumed a serious character.

She threw up everything administered by the stomach, both food and medicine, and also threw up large quantities of liquid, black or greenish-black in color, and having an odor between that of urine and fæcal matter.

This condition lasted four or five days before it finally gave way, during which time her kidneys nearly ceased to secrete and she voided no urine for thirty-six hours, the stomach probably acting, in a measure, vicariously. At the end of this day and a half, less than a pint of urine was found in the bladder by the use of the catheter, and for several days she voided no urine except once in twenty-four hours when the catheter was used. One after another her distressing symptoms disappeared, her strength increased, also her flesh, though at no time was she emaciated. She was under observation for ten

months, and when she left, her sensations were practically normal over her entire body and her bodily functions had assumed their normal regularity, and she still reports herself as in good health.

The case that has prompted this paper is one of extreme hysteria, *hysteria major*, as it is called, quite common in some portions of Europe, comparatively rare in this country.

The idea so common in the popular mind that hysteria is a disease void of danger to the individual affected, and the freaks of temper this class of patients so often indulge in, so influence the attention given to these sufferers that they receive little thought, and often the most tactless management possible; hence numbers of them go to form that large army of "shut ins," many of whom should be useful members of society.

The diagnosis of hysteria is usually overlooked in the less severe cases and is frequently jumped at in the more aggravated forms, and the object of the study prompted by the case reported is to show the important relation that this disorder may have to the vital functions, and to consider the importance of anæsthesia as a diagnostic sign.

That hysterical disorders may be serious enough to prove fatal has been stated by so renowned an authority as Charcot, and I have seen the *globus* so pronounced and persistent that I am sure the patient would have succumbed to inanition but for rectal feeding. I have also seen spasm of the respiration so severe as to be alarming, and death has been known to occur from hysterical spasm of the glottis. The heart is usually not influenced much in this disorder, but in the case reported in this paper it became very weak and beat irregularly. It would be evident also that such vomiting, with stoppage of the bowels and suppression of urine, as occurred in the case reported, could not last indefinitely.

The importance of anæsthesia as a diagnostic sign in hysteria does not rank with *globus*, or *hyperæsthesia*, which are much more frequently encountered; but when it does occur, it is of marked importance, and should be looked for systematically, especially as it is one of the symptoms seldom complained of by the patient, for the patient only discovers the anæsthesia by accident.

When anæsthesia occurs in hysteria it is usually after a pronounced hysterical attack. Its distribution and depth vary much in different cases.

The classical varieties of distribution are, over one half of the body, hemianæsthesia; over the lower extremities, paranæsthesia, and over isolated spots or islets which not infrequently follow in outline the shape of a sock or mitten.

In rare instances the whole body may be anæsthetic. The location and outline of the anæsthesias do not follow any particular nerve distribution, and are apt to vary from time to time in the same subject. In this latter particular the case reported was somewhat exceptional, as it also was in the manner and extent of its distribution. The depth of anæsthesia may involve all

sensation, including the muscular or location sense, or it may be only tactile anæsthesia, to which may be added analgesia, thermo-anæsthesia, and the loss of the muscular sense, making it complete.

Ischæmia is usually present, and was in the case reported, but the deep puncture with a good-sized surgical needle was followed by bleeding, and ecchymosis was produced by a slight contusion.

Paralysis may accompany the anæsthesia, but such is usually not the case, muscular weakness only being present. However, anæsthesia frequently accompanies hysterical paralysis, and, when it does, the anæsthetic area usually corresponds to the area of paralysis.

I have already said enough to fulfil the object of this short paper, and time will not permit the consideration of other branches of this very broad subject.

Therapeutical Notes.

For Stimulating the Appetite in Chlorosis.—Dr. Max Kahane recommends the following (*Berliner klinische Wochenschrift*, 1901, page 20):

R Compound tincture of cinchona 1 ounce;
Tincture of orange peel 1 "

M.

The dose is from 15 to 20 drops in half a glassful of water before meals.

Veil's Pyrogallic Acid Treatment of Lupus.—Captain W. D. Sutherland, I. M. S. (*Indian Medical Gazette*, November, 1900), gives the following treatment (originated by Veil, of Kannstadt) as being in use at Herxheimer's clinic at Frankfurt, and, moreover, endorses its efficacy from his own experience:

The larger tubercles are touched with a point of lapis infernalis (lunar caustic), and this treatment helps the physician in his diagnosis; for where no tubercle exists, there the skin remains unbroken when the point is pressed well down; whereas, when the skin is affected, a marked solution of continuity is left. After touching the larger tubercles with the point, the whole affected surface is covered with this salve:

R Pyrogallic acid from 1 to 10 parts;
Vaseline to 100 "

M. Ft. unguent.

Treatment is begun with a 1-per-cent. or 2-per-cent. salve, and the strength is then increased as the patient becomes used to the action of the acid, which seeks out the tuberculous patches, leaving the healthy tissues untouched. The part is kept constantly smeared with the salve, and when marked improvement results from the application of 8- or 10-per-cent. ointment the strength of the salve is gradually reduced to 8 or 6 per cent., then to 4 or 2 per cent., and finally to $\frac{1}{2}$ per cent.

Captain Sutherland says: "That lupus can be well treated thus with good cosmetic results, I have had ample opportunity of judging, for lupus is very common in this part of the world."

During the treatment the patient's urine is examined once a week for albumin and casts, as a slight nephritis may be set up by absorption of the pyrogallic acid.

NEW YORK, SATURDAY, FEBRUARY 16, 1901.

THE NEW YORK STATE COMMISSION IN LUNACY.

IN both the Senate and the Assembly there are bills pending which, if they should be enacted, would repeal the existing provision of law by which the president of the Commission in Lunacy is required to be a physician who has had five years' actual experience in the care and treatment of the insane, also experience in the management of institutions for the insane. Such repeal is opposed by the State Charities Aid Association and by the New York Neurological Society, and it is our decided opinion that these two deservedly influential organizations found their opposition upon cogent reasons.

These two reasons are given by the State Charities Aid Association: 1. The extensive powers possessed by the commission require that it should include a member who knows about the construction and equipment of buildings specially designed for the treatment and custody of the insane; who has experience as to the requisite number and qualifications of physicians, nurses, and employees in the State hospitals and as to their proper salaries; who has knowledge of the quantity and quality of food supplies to be allowed; and who knows in regard to other important matters which require the judgment of a physician who has had experience in the management of institutions for the insane. 2. The commission is practically a court of appeals to which an appeal may be taken in behalf of any person who is forcibly detained in a private or public institution for the insane, but is alleged not to be insane. The insanity law, says the association, requires the commission, when inspecting asylums, to give patients an opportunity to converse with its members apart from the officers and attendants of the institution, and confers upon it absolute power to discharge any patient who, in its judgment, is wrongfully detained. Thus the commission is made a most important safeguard of the rights and liberties of citi-

zens, so that it is of supreme importance that its one medical member should be familiar with all phases of insanity and experienced in the treatment of the insane. The enactment of the pending bills, the association declares, would be injurious to the welfare of over 23,000 insane patients now in the hospitals and private asylums of the State, and would imperil the liberty of citizens who might wrongfully be incarcerated.

To practically these same reasons the New York Neurological Society adds the requirements that the medical member of the commission should be familiar with the most advanced methods in the care and treatment of the insane, and that he should have the knowledge requisite to enable the commission to so direct the working energies of the State hospital physicians as to add to our knowledge of the means of preventing and curing insanity.

Both organizations have thought the matter one of sufficient importance to lead them to print and circulate expressions of their views, and most assuredly they have not overrated it. We cannot conceive of any creditable motive for seeking to do away with a proviso that is most precious in the interest of the insane and of the general public. The physician who has not had considerable experience in the actual management of an institution for the insane—and we believe an experience of five years to be none too great—is not qualified to properly perform the varied and responsible duties of a member of the lunacy commission, and we are confident that the legislature of the State will perceive the inexpediency and downright injustice that would be wrought by such legislation as the passage of the pending bills. They are known as Senate bill No. 255, introduced by Mr. Brackett, and Assembly bill No. 396, introduced by Mr. Fish.

THE ARMY MEDICAL SERVICE IN THE PHILIPPINES.

WE have received a printed copy of the report of Colonel and Assistant Surgeon-general Charles R. Greenleaf, chief surgeon for the Division of the Philippines, for the year ending July 31, 1900. It relates chiefly to the period beginning with January 1st and ending with July 31st, the report for the preceding months having been made by Dr. Greenleaf's predecessor, Lieutenant-colonel and Deputy Surgeon-general A. A. Woodhull. The pamphlet, which seems to have been printed in Manila, is a creditable piece of work from the point of view of typography, but the proof-reading might have been improved.

The scarcity of medical officers in the Philippines is a prominent theme, constituting as it has since the beginning of our occupation, says Dr. Greenleaf, the greatest source of anxiety that has confronted the chief surgeons. At the time of the report this scarcity was more felt than it had ever been before, and, in round numbers, there were 10,000 men serving at posts that had practically no medical attendance. At that time the number of posts was 375, and was constantly increasing, while there were only 336 medical officers on duty in the islands, and but 233 of these officers were available for post service. The hundred additional acting assistant surgeons promised by the surgeon-general, says Dr. Greenleaf, would not suffice to make good the deficiency, unless soon reinforced by more, because there were then about fifty acting assistant surgeons whose terms of contract had expired and who were anxiously awaiting their release, and every day was adding to the list.

Dr. Greenleaf declares that he is now more than ever impressed with the fundamental weakness of the contract system. To place civilians without real rank or authority in the position of quasi-officers, he says, is an injustice to the surgeon himself and to the Medical Department, which has to be responsible for his acts; his contract is made for a year only, and at the end of that time he can demand his release from duty, no matter how urgently his services may be needed; while performing an officer's duty, he is not an officer, and the knowledge that this is the case makes him less exact and prompt in bending to military discipline. The surgeon may even desert and leave his post unsupplied with medical attendance, as has actually happened in one instance, and there is no law, so far as Dr. Greenleaf knows, by which he can be punished or brought back and made to perform his duties; he gets a year's experience and is just beginning to learn his work when his contract expires, an untrained man takes his place, and the process begins anew. To discipline and train men for so short a service is a hopeless task. In short, says Dr. Greenleaf, the contract system is the least economical, the least effective, and the least satisfactory that could be devised. He is decidedly of the opinion that, if the present acting assistant surgeons were all to receive commissions as lieutenants of volunteers, to serve for two years or until their services were no longer required, the evils of the present system would in large part be remedied. The professional qualifications of the men who are now sent to the Philippines are satisfactory, says Dr. Greenleaf, and he expresses the opinion that they require only a

fixed status, a burden of responsibility, and a longer service to make them extremely valuable. What Dr. Greenleaf says concerning these matters is strongly corroborative of what has been freely urged upon the government, and we hope that his views will yet prevail.

THE MEDICAL ASPECTS OF THE SIEGE OF PEKING.

The opening article in the January number of our excellent contemporary, the *China Medical Missionary Journal*, by Lillie E. V. Saville, M. D., is entitled The Siege of Peking—Its Medical Aspects. It appears that there was a large proportion of physicians among the besieged, twenty in all, besides a retired naval surgeon, and nine of them were women. On June 21st the International Hospital was organized in the British Legation. The staff consisted of Dr. Poole, of the British Legation, and Dr. Velde, of the German Legation. The women physicians were asked to act as nurses, and they gladly did so, says Dr. Saville. Miss Lambert, of the S. P. G. Mission, took charge of the nursing service, and three American ladies superintended the kitchen and stores, which were "beyond all praise." "Nowhere else," says the author, "was there such fragrant pony soup, such really eatable mule stew, and I think the officers and men often thought it was worth while to be *slightly* wounded to get a few days' good feeding."

"The unity which was such a striking feature of the siege in Peking," says Dr. Saville, "was nowhere more manifest than in the International Hospital." "Differences of nationality, creed, and professional status," she goes on to say, "were laid aside, and all worked with much happiness together." Nevertheless, it was judged best to group the patients by nationality so far as possible, in order that every one of them might have somebody to talk with. The Italians and French were together, the Russians were in a room by themselves, and "one room was always full of the bright, interesting little Japs." The English and Americans naturally went together. In a ward devoted to officers and civilian volunteers there were British, American, German, French, Italian, Austrian, Dutch, Australian, and Russian patients. Comfortable bedding, much of it the fruit of "very much self-denial on the part of others," was almost miraculously furnished for every patient; there were very few bedsteads, but every man had a mattress and sheets and pillows. The most varied expedients were resorted to to furnish bedding and clothing. The lower pillows were made of the straw jackets of wine

bottles; eider-down quilts were cut up to make soft pillows; and "a long piece of Chefoo silk, found in the Mongol market, made shirts, as did best damask linen and bright yellow cotton. 'Imperial' shirts these were called."

Nearly all the material for surgical dressings was supplied by Dr. Velde, who, fortunately, had a large supply, all of the German army type. He also had a sterilizer, and that had to be used when it finally came to making muslin curtains take the place of prepared gauze, and bags of peat or sawdust the place of wool. The hospital was small at first, occupying only two rooms in a bungalow, but it grew with the increase of the wounded until at last there was an operating-room with two tables. The instruments for an operation were always sterilized, there were five wards, and there were other special quarters for the sick and wounded. As the fighting was all behind barricades, wounds of the head and of the upper extremities greatly preponderated. Deep wounds were seldom examined thoroughly at the outset, even when there was no aperture of exit, but they generally did well, the clotted blood proving "the best air-proof medium that could have been devised."

Dr. Saville appends to her article a tabular statement of the casualties, distinguishing the nationalities of the patients. There were fifty-six Americans engaged. Seven of them were killed or died of wounds, and ten received wounds that did not prove mortal. There were forty-eight Frenchmen, and every one of them was wounded, eleven fatally; but it is explained that the French alone counted wounds that did not incapacitate the men for duty. We find it difficult to understand, however, how, of the twenty-five Japanese, five were mortally wounded and twenty-one others were wounded, unless one man, having recovered from his first injury, was wounded and counted again, but this does not seem to be stated. The deaths from disease were remarkably few, only two in a total force of 407 men. They were both among the Russians and were due to dysentery.

No notes of the cases were kept during the siege, for "no one had the time," and the table given is said to be but a summary of "the barest statistics" kept. Dr. Saville declares that she has no data, and that her account is "the merest sketch" from memory. We have no doubt of its substantial accuracy, and it is certainly of great interest. Incidentally, the author gives brief histories of a few individual cases. One of them, that of an Austrian lieutenant, is noteworthy. A shell wound carried away a portion of the vault of the cranium about two

inches square, exposing the dura mater and the brain. There was very severe hæmorrhage from the longitudinal sinus, but the patient did remarkably well, and in about a fortnight left the hospital as a convalescent. It was apparently after that time that "a good deal of pus began to well up from the wound," and the opening was enlarged by chiselling and some pieces of dead bone and of lead were removed. In a few days the patient was up and about again. He again left as a convalescent on the day of the relief, but two days later he was brought back with a temperature of 104.5° F. He was very restless and delirious, and on the following day a purpuric rash developed on his hands and quickly spread to the trunk and limbs. A diagnosis of typhus was made, but subsequently this was changed to one of meningitis. The hospital was then broken up and the patient had to leave, but a fortnight later Dr. Saville learned from Dr. Velde that the lieutenant had recovered completely and had left Peking.

DISEASE AND VICIOUSNESS.

A WELL-KNOWN English judge had before him on one occasion a person charged with shoplifting. The judge's demeanor showed very clearly that he was not in sympathy with the effort of the prisoner's counsel to excuse his client on the score of irresponsibility. "Is your lordship aware," asked the counsel, "that there is a disease known to physicians by the name of kleptomania?" "Perfectly," replied the judge, "and I am sent here to administer a drastic remedy for it." Because the tendency to habitual drinking is often a disease, it does not therefore follow that it is not frequently merely a vice. The authorities at Bellevue, it seems, are beginning to comprehend this, and, in the case of chronic "repeaters" who "get on a jag" with the consciousness that it will be worked off in the comparative comfort of a good bed in the alcoholic ward, shelter from inclement weather, and a sufficiency of square meals, have determined henceforth to transfer all such offenders to the police authorities for more suitable and adequate treatment. One "patient" already has been transferred to "the island" for six months. This is as it should be, save in cases in which careful observation shows collateral evidence making indisputable the defect of irresponsibility.

AN EXCELLENT PRECEDENT.

To a Parisian lady doctor of medicine must be credited the honor of a brave and, strange to say, successful legal vindication of a physician's rights. Some little time back she brought suit in the Paris courts against the father of a child upon whom she had operated for

laryngeal abscess, to collect the amount of her fees, some 100 francs in all. The parent entered as a defense that the operation had been unskillfully performed and, so far from benefiting the patient, had done positive harm, and offered in support of this contention a certificate from a dentist. The court called upon Professor Brouardel, the eminent medical jurist, for his opinion, which was eminently satisfactory to the lady; whereupon she boldly entered further action for damages, on the ground that the defendant had supported his opposition to her claim by misstatements prejudicial to her professional reputation. The court heard the arguments in detail, and decided for the plaintiff on both counts, awarding her damages of fifty francs in addition to the amount of her bill. We congratulate both the lady and the court on this eminently sensible judgment.

THE AMENDED BELL BILL.

WE are glad to learn that the essential portion of the bill has now been amended to read as follows: "Any person shall be regarded as practising medicine within the meaning of this act who shall profess to heal or who shall give treatment to any other person by the use of any remedy, agent, or method whatsoever, whether with or without the use of any medicine, drug, instrument, or other appliance, for the relief or cure of any wound, fracture, or bodily injury, infirmity, physical or mental, or other defect or disease. This article shall not be construed as prohibiting the manufacture, sale, or use of patent medicines or proprietary articles where no diagnosis is made by the maker or seller thereof, or the giving of temporary relief by a registered pharmacist, or any person in an emergency," etc. We learn that the bill is not now likely to meet with serious opposition except from the "osteopaths," who certainly ought not to be able to prevail against it.

THE SUPRARENAL CAPSULE AS A REMEDY FOR SNORING.

It has come to our knowledge that a middle-aged man who for years had had a household reputation as a most sonorous snorer, began to take a preparation of the suprarenal capsule as a remedy for chronic nasal catarrh. Not only did it mitigate the supersecretion of mucus, but his snoring practically ceased. Whether or not the occurrence was anything more than a coincidence, we do not undertake to say.

THE OKLAHOMA MEDICAL JOURNAL.

WE are glad to see the evidence of our young contemporary's prosperity shown in the enlargement of its January number. It is handsome in appearance, too, and betokens gratifying activity in medical matters in the Territory.

News Items.

Society Meetings for the Coming Week:

MONDAY, *February 18th*: New York Academy of Medicine (Section in Ophthalmology and Otology); New York County Medical Association; Hartford, Connecticut, Medical Society; Chicago Medical Society.

TUESDAY, *February 19th*: New York Academy of Medicine (Section in General Medicine); Buffalo Academy of Medicine (Section in Pathology); Ogdensburgh, N. Y., Medical Association; Syracuse, N. Y., Academy of Medicine; Medical Societies of the Counties of Chemung (quarterly), Kings, and Livingston (quarterly), N. Y.; Baltimore Academy of Medicine.

WEDNESDAY, *February 20th*: Medico-legal Society, New York; Northwestern Medical and Surgical Society of New York (private); New Jersey Academy of Medicine (Newark).

THURSDAY, *February 21st*: New York Academy of Medicine; Brooklyn Surgical Society; New Bedford, Massachusetts, Society for Medical Improvement (private); Medical Society of City Hospital Alumni, St. Louis; Atlanta Society of Medicine.

FRIDAY, *February 22d*: New York Clinical Society (private); New York Society of German Physicians; Yorkville Medical Association, New York (private); Philadelphia Clinical Society; Philadelphia Laryngological Society.

SATURDAY, *February 23d*: New York Medical and Surgical Society (private).

Naval Intelligence:

Official List of Changes in the Medical Corps of the United States Navy for the Two Weeks ending February 9, 1901:

BERTOLETTE, D. M., Medical Inspector. Ordered to the *New York*.

BUCHER, W. H., Assistant Surgeon. Detached from the Naval Hospital, New York, and ordered to the Naval Hospital, Norfolk, Virginia.

DERR, E. Z., Medical Inspector. Ordered to the Naval Academy.

DUBOSE, W. R., Surgeon. Detached from the Naval Academy and ordered to the *Wisconsin*.

GROVE, W. B., Assistant Surgeon. Detached from the *Vermont* and ordered to the Naval Hospital, New York.

GUTHRIE, J. A., Passed Assistant Surgeon. Detached from the *Franklin* and ordered to the *New York*.

MCCORMICK, A. M. D., Surgeon. Detached from the Naval Hospital, Norfolk, Virginia, and ordered to the Naval Academy.

SPEAR, R., Passed Assistant Surgeon. Detached from the *Buffalo* on arrival at Cavite and ordered to the *Isla de Luzon*.

STONE, M. V., Assistant Surgeon. Detached from the *Isla de Luzon* and ordered to the *Buffalo*.

Army Intelligence:

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from January 26 to February 9, 1901:

CROSBY, WILLIAM D., Captain and Assistant Surgeon, is detailed as a member of the board of officers appointed to meet at the Army Building, New York, to examine officers of the Corps of Engineers, United States Army, for promotion, *vice* EUCLID B. FRICK, Captain and Assistant Surgeon.

HARTSUFF, ALBERT, Colonel and Assistant Surgeon-General, United States Army. His retirement from active service, February 4, 1901, by operation of law, is announced.

KEAN, JEFFERSON R., Major and Surgeon, United States Volunteers, will proceed to Washington and report in person to the president of the board of officers convened in that city for examination as to his fitness for promotion.

KILBOURNE, HENRY S., Major and Surgeon, is detailed as a member of the board of officers appointed to meet at the Army Building, New York, to examine officers of the Corps of Engineers, United States Army, for promotion, *vice* WILLIAM STEPHENSON, Major and Surgeon.

WOOD, MARSHALL W., Major and Surgeon, United States Army, will proceed to St. Louis and take temporary charge of the medical supply depot at that place during the absence of JOSEPH B. GIRARD, Major and Surgeon. Upon the return of the latter officer he will rejoin his proper station.

Marine-Hospital Service Health Reports:

The following cases of small-pox, yellow fever, cholera, and plague were reported to the surgeon-general during the week ending February 9, 1901:

Smallpox—United States.

Jacksonville, Florida.....	Jan. 26-Feb. 2..	1 case.	
Chicago, Illinois.....	Jan. 26-Feb. 2..	4 cases.	1 death.
Lawrence, Kansas.....	Jan. 26-Feb. 2..	2 cases.	
Leavenworth, Kansas.....	Jan. 1-31.....	4 cases.

Marine-Hospital Service:

Official List of the Changes of Stations and Duties of Commissioned and Non-Commissioned Officers of the United States Marine Hospital Service for the Seven Days ending February 7, 1901:

- BAILHACHE, PRESTON H., Surgeon. Relieved from duty as chairman of the board for the physical examination of Second Assistant Engineer R. F. HALPIN, R.C.S.
- BALLARD, J. C., Acting Assistant Surgeon. Granted leave of absence for five days from February 7th.
- CORPUT, G. M., Assistant Surgeon. Bureau order of January 26th, directing Assistant Surgeon CORPUT to proceed to Cleveland for temporary duty, revoked.

FRANCIS, EDWARD, Assistant Surgeon. To proceed to Cleveland and assume temporary command of the service during the absence on leave of Surgeon PETTUS.

VAUGHAN, G. T., Surgeon. Detailed as chairman of the board for the physical examination of Second Assistant Engineer R. F. HALPIN, R.C.S.

Infectious Diseases in New York:

We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported for the two weeks ending February 9, 1901:

DISEASES.	Week end'g Feb. 2.		Week end'g Feb. 9.	
	Cases.	Deaths.	Cases.	Deaths.
Typhoid Fever.....	27	15	27	9
Scarlet Fever.....	326	14	369	30
Cerebro-spinal meningitis.....	0	0	0	0
Measles.....	116	2	145	5
Diphtheria and croup.....	361	40	260	40
Small-pox.....	50	2	17	6
Tuberculosis.....	282	90	282	165

The Sale of Horse Meat Prohibited.—The board of health of New York City has prohibited the future slaughter of horses and the sale of meat from all such animals. Section No. 86 of the Sanitary Code was amended to conform to this resolution.

Murderous Assault on a New York Physician.—News comes from El Paso, Texas, that Dr. Alfred E. Meyer, of New York, has been stabbed in that city and robbed of \$1,000. The report comes via St. Louis in a special to the *New York Times* for February 14th, but is at the time of writing unconfirmed.

A Course of Clinical Lectures by Dr. T. D. Crothers. of Hartford, Conn., on the Neuroses and Psychoses of Spirit and Drug Diseases, at the hall of the New York School of Clinical Medicine, 328 West Forty-second Street, which the members of the medical profession are cordially invited to attend. The first of the lectures will be given on February 18th, at 8 P. M.

Indiana's Law against Christian Scientists.—Senator Wood has introduced a bill in the State legislature making it a felony punishable by imprisonment in the penitentiary when Christian Scientists treat cases of illness and death results. The purpose of the bill is entirely to exclude the practice of Christian Science in Indiana.

An Anti-vaccination Movement.—The Anti-vaccination Society of St. Paul, Minn., was recently organized in that city. At the meeting of the Ramsey County Medical Society there the following evening resolution were passed indorsing the good work of vaccination by the Minnesota State Board of Health and the local boards, and the following officers were elected: President, Dr. Cornelius Williams; vice-president, Dr. John L. Rothrock; secretary, Dr. Ethelbert F. Greer; treasurer, Dr. Frederick Leavitt; necrologist, Dr. A. F. Whitman.

Praise for New York Medical Schools.—The annual report of the State board of regents, recently submitted to the legislature at Albany, contains the following: "It speaks very well for New York medical schools that of the papers submitted by their graduates the average number rejected was only about one for every four graduates, a compared with one for every graduate of schools in other

States, and two for every graduate of schools in foreign countries. In addition to candidates from schools in which there was at least one failure, thirty-nine graduates of four New York schools and eighty-five graduates of forty-two schools in other States and countries were examined."

Forestry Reserves for Consumptives.—The Dauphin County (Pa.) Medical Society has invited Forestry Commissioner Rothrock to talk before it on a proposed scheme for the care of consumptives, which contemplates the establishment of camps on the various forest reservations of Pennsylvania, which may be suitably located for the purpose, where persons suffering from consumption, and who have not the means to go to California, can spend several months in the summer. It is probable that the first camp will be opened on the reservation in Clinton county, which has an elevation of 2,000 feet above the level of the sea. This reservation has an area of 45,000 acres and is adjoined by two other large reservations.

Massachusetts Legislation Regarding Christian Scientists.—A bill has been introduced into the Massachusetts legislature, aimed at Christian Scientists, clairvoyants, and persons practising magnetic healing and mind cures. The bill aims to have inserted in the present medical law (chapter 458 of 1894) a new section providing that "whoever, not being registered, shall advertise or hold himself out to the public as a healer of disease, or able to abolish disease or the symptoms of disease, or as competent to do surgery, or shall in any way treat or prescribe for the sick or injured for gain, shall be punished by a fine of not less than \$100 or more than \$500 for each offence, or by imprisonment in jail or three months, or both."

Massachusetts Board of Registration in Medicine Attacked.—Dr. Immanuel Pfeiffer has preferred charges against the Massachusetts State Board of Registration in Medicine to Governor Crane, and asks for their removal. The petition charges that the board has not made annual reports, as required by statute, and that his method is pursued in order that they may find out what restrictive amendments can be introduced with a fair prospect of having them passed, and not to give his information to the opposition before it is too late to introduce counter measures before the legislature. The board, it is said, has refused registration to a large number of persons who have earned diplomas in such medical schools as Harvard, Tufts and the Physicians and Surgeons. The secretary of the board says that the charges are groundless.

Michigan State Board of Registration.—Governor Bliss has appointed the following-named members of the State board of registration in medicine. The terms of the first five end on October 1, 1901: Dr. Joseph B. Grisvold, Grand Rapids, regular school; Dr. George E. Ranney, Lansing, regular school; Dr. Walter H. Sawyer, Hillsdale, regular school; Dr. Austin W. Alvord, Battle Creek, regular school; Dr. Henry B. Landon, Bay City, regular school; Dr. Joseph H. Cowell, Saginaw, homœopathic school, term ends 1901; Dr. Albert Lodge, Detroit, homœopathic school, term ends 1903; Dr. William Bell, Belding, eclectic school, term ends 1901; Dr. Henry J. Maynard, Hartford, eclectic school, term ends 1903; Dr. John Kost, Adrian, psychomedical school, term ends 1901.

Receiver Asked for a Sanitarium.—Application was recently made to Justice Dickey for a receiver for the St. Martha's Sanitarium, Brooklyn. In a suit brought by John D. and Joseph Stafford, judgment had been taken by default against the institution for \$7,000, and it was held that the defendant had confessed judgment for \$18,000 and there were no assets. In opposition, the institution claimed that since the controller had cut off \$4,000 from the sanitarium and dispensary it had been compelled to rely on voluntary contributions. To appoint a receiver would discourage charitable people from giving money. Since the support from the city had been discontinued most of the patients had been removed to the Flatbush Asylum. Justice Dickey reserved decision.

Diphtheria.—The marine barracks and prison in the navy yard at Boston and the receiving ship *Wabash* have been quarantined on account of diphtheria. Within a few days about thirty men have been sent to the Naval Hospital in Chelsea. None of the cases is called serious. —The diphtheria situation at Eastport, L. I., is very favorable, and notwithstanding the fact that there have been seven cases of the dread malady, some of which were affected by the most aggravated type of the disease, not a single death has occurred, and there is every probability that all the cases will recover.

Typhoid.—The typhoid outbreak at East Hampton, L. I., last summer has been investigated for the State board of health by Professor Landreth, of Union College. He finds that the cause was the proximity of Camp Wikoff. The report says there is little doubt that typhoid became established at East Hampton by soil implantation, and that it was disseminated either through the agency of percolation or through the air. Professor Landreth says that unless vigorous sanitary measures are taken there is a prospect of the disease developing into an epidemic during the coming season.

Small-pox.—Exciting scenes have marked the invasion of "Little Italy," an Italian colony of New York City, by the physicians of the health board, and for some time the doctors and the policemen assisting them had a lively time of it. An incident of the raid was the refusal of a policeman to allow his stricken child to be taken to North Brother Island, and his final consent when the mother was allowed to accompany the patient. Small-pox is reported to have developed very rapidly among the Italians. Many patients were concealed in crowded tenements, and the physicians discovered children hidden in ice-boxes, closets, trunks, and barrels. Several times when houses were invaded women rushed out carrying bundles under their arms. These bundles were found to be children suffering from small-pox. —From Watertown, N. Y., comes the report that a small-pox patient has been placed on exhibition, the health department taking that remarkable method to convince skeptical physicians and others that the cases of small-pox in town are actually that disease. The man afflicted was placed on a couch before a large landscape window at his home which faces directly upon the sidewalk. —Fort Dodge, Iowa, is suffering considerably from small-pox, the result of an innocent country dance. A germ-infected person probably attended the gathering and scattered broadcast the infection. Livermore, where most of the cases are located, has been quarantined, and the residents are alarmed over the spread of the sickness. —There is a regular epidemic of small-pox in Chi-

ago and schools have been closed and every precaution has been taken to stop the spreading of the disease. A report has been circulated, but not been substantiated, that the employees of the large store called The Fair are afflicted with small-pox.—In Buffalo an order has been issued to the children in parochial schools to the effect that they must show vaccination certificates, permit themselves to be vaccinated by a private physician or by a health department physician. This is to be done to prevent any contagious disease from becoming epidemic in the city.—Frederick Bowley, president of the Borough of Queens, has had his office converted into a free vaccination station for the school children and the boys and girls in mercantile life.—Wisconsin has suffered considerably from small-pox, but now the cases are dying out and the numbers of sick have lessened greatly.—A bill has been introduced in the Utah legislature to compel all the people to be vaccinated within a certain time.—Another State that is afflicted with the disease is Texas, and but few nurses can be obtained to care for the sick.—A report from Cleveland, O., states that small-pox is increasing, though most of the cases are in a mild form.

Officers of the Schenectady County Medical Society.

—At the annual meeting of the Schenectady County (N. Y.) Medical Society the following officers were elected: President, Dr. C. F. Clowe; vice-president, Dr. J. F. McEncroe; secretary, Dr. E. J. Wiencke; treasurer, Dr. Joseph Raymond.

The Medico-legal Society of Philadelphia at a recent meeting elected the following officers: Dr. L. H. Adler, president; Dr. S. Wolfe, first vice-president; Dr. W. Reber, second vice-president; Dr. C. W. H. Clewell, secretary; Dr. J. W. P. Peltz, treasurer, and Dr. J. D. Nash, librarian.

The Associated Health Authorities and Sanitarians of Pennsylvania met recently at Harrisburg and elected the following officers: First vice-president, Crosby Gray, Pittsburgh; second vice-president, Dr. H. H. Whitcomb, Norristown; third vice-president, E. S. Wagoner, Mechanicsburg; treasurer, Jesse C. Green, West Chester; secretary, Dr. W. B. Atkinson, Philadelphia.

The Atlantic County Medical Society.—The annual meeting of the Atlantic County Medical Society was held recently at Atlantic City, N. J., and the following officers elected for the ensuing year: President, Dr. Theodore Boysen, Egg Harbor City; vice-president, Dr. William Edgar Darnall, Atlantic City; secretary and treasurer, Dr. Theodore Senseman, Atlantic City; reporter, Dr. A. Burton Shimer, Atlantic City.

The Otsego County Medical Society convened for its semi-annual session at Oneonta, N. Y., on January 15th. The programme was as follows: Vice-president's address, Dr. A. W. Cutler; paper, Some Suggestions to the Practitioner, Dr. A. J. Butler; paper, Gangrene, Dr. Rupert W. Ford; discussion led by Dr. C. E. Parish; paper, The Physician, a Man and a Citizen, Dr. J. K. Leaning; report of cases, led by Dr. B. W. Dewar.

The Brashear Medical Society met in quarterly session at Bardstown, Ky., on January 15th. Among the subjects discussed were the following: The Use and Abuse of Atropine in the Eye, by Dr. A. O. Pfingst, of Louisville; The Importance of the Early Recognition of

Eye Strain, by Dr. Charles McClure, of Cox's Creek; The Importance of Rest as a Therapeutic Measure, by Dr. A. G. Blincoe, of Bardstown; Fracture of the Neck of the Femur, by Dr. Irvin Abell, of Louisville; Pustilla in Orchitis, by Dr. B. E. Gore, of Bardstown.

The Annual Banquet of the Buffalo Medical Union was held at the Genessee Hotel, Buffalo, on January 23d, the following members and guests being present: Dr. R. L. Banta, Dr. DeWitt C. Green, Dr. A. A. Hubbell, Dr. S. S. Green, Dr. Renner, Dr. Westinghouse, Dr. Buswell, Dr. Meyer, Dr. W. D. Green, Dr. Diehl, Dr. Krauss, Dr. Tobie, Dr. Koeneron, Dr. Ingraham, Dr. J. C. Thompson, Dr. J. G. Thompson, Dr. J. H. Potter, Dr. Rasbach, Dr. Fell, Dr. Brown, Dr. Bissell, Dr. S. G. Dorr, Dr. L. B. Dorr, Dr. Congdon, Major Briggs, and Mr. Stockney.

Organization of Bellevue Graduates.—Graduates of Bellevue Hospital and of the New York University Medical College have organized at Chicago a western alumni association of the two institutions named. The reason for a joint association of the two colleges is that they are now under the same management. The following officers were elected: President, Dr. J. F. Podd; first vice-president, Dr. James G. Tiernan; second vice-president, Dr. James McKinlock; secretary, Dr. William O. Nance; executive committee, Dr. Hugh P. Patrick, Dr. J. S. Christison, Dr. J. Grinke, and Dr. Sange Brown.

Annual Dinner of the Alumni Association of Kings County Hospital.—The eighth annual dinner of the Alumni Association of the Kings County Hospital was held recently at the Clarendon hotel, Brooklyn. Covers were laid for seventy-five, the tables being arranged in the form of a hollow square and the decorations red carnations. The Alumni Association of the Kings County Hospital numbers about two hundred physicians, but of this number scarcely more than seventy-five are available by reason of their not living near or in the borough where the annual dinner is held. The speakers were John Green, of the board of education; Dr. C. F. McGuire, Dr. Harmon Smith, of Manhattan, and Commissioner of Charities A. Goetting.

The Massachusetts Association of Boards of Health held its annual meeting in Boston on January 24th, the president, Dr. Samuel H. Durgin, in the chair. The following officers were elected: President, Dr. Henry P. Walcott, of Cambridge; vice-presidents, Dr. Samuel H. Durgin and Dr. Samuel H. Abbott; secretary, Mr. James C. Coffey, of Worcester; treasurer, Dr. James L. Field, of Lowell. Executive committee (for two years) Dr. W. H. Chapin, of Springfield; Dr. D. S. Woodworth, of Fitchburg; Dr. F. W. Kennedy, of Lawrence; Dr. V. S. Everett, of Hyde Park, and Dr. Walter C. Kite, of Milton.

Papers were read by Dr. Palmer, of South Framingham, who treated of Glanders in a Human Patient, and by Mr. William Lyman Underwood, of M. I. T., who considered the drainage of certain wet, rotten, and spongy lands between Cambridge and Belmont.

Lack of Funds Leads to Closing of a Hospital.—For lack of a yearly guarantee fund of \$10,000, the Mothers and Babies' Hospital at Lexington Avenue at Fifty-second Street, New York City, must close during the coming month. It has been supported for eight years by voluntary contributions.

American Medical Missionary College and Hospital.

—This institution proposes to expend \$150,000 in the erection of two four-story buildings for its own use in the neighborhood of the Cook County Hospital, on Harrison Street, Chicago. At present the senior year students only study in Chicago, the preliminary courses being pursued in the Battle Creek Sanitarium.

Officers of the Detroit Polyclinic Hospital.

—At the annual meeting of the Detroit Polyclinic Hospital the following officers were elected: Dr. W. H. Poole, president; Dr. J. E. Davis, vice-president; Dr. S. E. Sander-son, secretary; Dr. B. W. Pasternacki, treasurer; trustees, Dr. E. Amberg, H. W. Yates, W. C. Thomson, J. E. Davis, L. Breisacher. The number of cases treated during the year was 2,295, and the number of new patients 633.

The Stony Wolde Sanitarium for Consumptives.

—A number of women who are interested in building a hospital for consumptive women at Stony Wolde, in the Adirondacks, held a meeting in the Dakota recently. Dr. Frieda Lippert and Dr. S. A. Knopf addressed those present, and a feature of the gathering was a solo by Mrs. Mabel McKinley Baer, wife of Dr. Baer and a niece of the President. Auxiliary associations have been organized in several parts of the city and State. A committee has been organized and is collecting funds to buy a site and erect the sanitarium.

Hospital Saturday and Sunday Association.

—The annual meeting of the Hospital Saturday and Sunday Association was held recently in this city. An election for officers and the board of trustees resulted as follows: President, George Macculloch Miller; vice-president, Isaac Wallach; recording secretary, George P. Cammann; corresponding secretary, Rev. George S. Baker, D. D.; treasurer, Charles Lanier. Board of trustees, George M. Miller, Isaac Wallach, Rev. George S. Baker, D. D., George P. Cammann, Charles Lanier, Jacob H. Schiff, William Alexander Smith, A. G. Agnew, John S. Bussing, George G. Wheelock, M. D., James Speyer, J. A. Stursberg, Robert Olyphant, O. Egerton Schmidt, R. Vander Ende, Walter H. Lewis, Louis Stix, Charles Renanld, Henry Maillard, W. Oliver Moore, M. D., Leonard Weber, M. D., Henry Rosenwald, Eugene H. Conklin, A. B. Ansbacher, A. H. Wellington, H. R. Kunhardt, R. J. Cross, Marcus M. Marks, Mrs. Edmund L. Baylies, and Mrs. James Speyer.

A Summary of the Report of the Committee of the Medical Board of Bellevue Hospital, appointed January 2, 1901, to investigate and report upon questions relating to the general administration of the hospital:

We are of the opinion that the rules and regulations of the hospital are correct upon the whole: that the various divisions and subdivisions of the force which is concerned in the conduct of the hospital are, as far as circumstances permit, organized upon correct lines; a division of authority has, however, existed, which has been responsible for the defective execution of the laws under which the hospital was supposed to live. This, as we stated to you some time ago, can be obviated by a head which places itself in contact with these various subdivisions and exercises immediate and vigorous control over all. This, we are glad to say, you have accomplished by installing Dr. Stewart.

But permanent improvement is rendered difficult,

and some of us believe impossible, in the face of the inefficiency of the paid employees as a class, and the wretched accommodations furnished to so large a portion of your staff, doctors and employees alike. Correct this and raise the *per capita* allowance of this hospital to a figure approximating that which obtains in like institutions in this city, and the crying evils will be permanently eradicated. Otherwise, the outcome of this effort at improvement will end as the many which have preceded it. Decent service requires fair pay and decent accommodations; to which end we earnestly recommend an increase in the *per capita* allowance, and that the main hospital building be replaced at once by a modern and more commodious structure.

We beg to call your attention to the subjoined comparative statement of the *per capita* allowance at this and other leading hospitals:

Per Capita Cost per Diem for Ward Patients.

St. Luke's Hospital.....	\$1.62
Presbyterian Hospital.....	2.44
Roosevelt Hospital.....	2.195
Mt. Sinai Hospital.....	1.38 $\frac{1}{4}$
New York Hospital.....	2.08
Pennsylvania Hospital.....	1.17
Massachusetts General Hospital.....	1.96
Boston City Hospital.....	1.77
Bellevue Hospital.....	1.21

Daily *per capita* cost for the Bellevue Hospital, estimated on the basis of total inmates.... \$0.6985

Selecting for comparison the five hospitals in the above list situated in New York City, it is seen that the average *per capita* allowance provided by them for each patient is \$1.98, as against \$1.21 for Bellevue Hospital; a statement all the more worthy of official consideration when we compare the commodious and well-equipped quarters in which their patients (18,907 in all) are cared for, with those in which at the Bellevue Hospital care for the 24,300 which fall to our lot.

(Signed) W. M. POLK, *Chairman*;
A. ALEXANDER SMITH,
GEORGE B. FOWLER,
ALEXANDER LAMBERT,
JOHN W. BRANNON.

Hospital Buildings and Endowments.—St. Anthony's Hospital and Orphanage of New York, a new Polish Catholic institution, is now ready to receive its charges, although the entire building has not neared completion. The hospital is provided with eight large wards, each of which has twenty beds, and besides these there are thirty private rooms. It is designed to provide a home for orphans and for aged people, as well as for the sick and the maimed. The building, although not nearly completed, is already sheltering a half dozen orphans, and for this part of the hospital there are nine Sisters of Charity in attendance. These attendants will be increased as the needs of the institution demand. A drug store, in charge of an experienced pharmacist, is in a section of the building, and on the second floor is a small chapel, which has eight very handsome windows, costing \$800. The hospital is located in a Polish neighborhood, at North Robey Street and North Hoyne Avenue, and it is through the efforts of Bishop Anthony Kozlowski and the generosity of his people that the institution has been built. All in need of help will be admitted, regardless of race or religion. For trustees of the institution, Bishop Kozlowski has associated with

himself as president, Joseph Sadowski, vice-president; Alexander S. Leszczynski, secretary; John Murawski, vice-secretary, and Jacob Dziewior.—Mayor Van Wyck has refused to grant the request of the Navy Department for a part of Blackwell's Island to be used as a naval park. He says that to do this it will be necessary to raze both the insane asylum and the hospital to get a space sufficiently large for a park. Commissioner Lantry suggests that the city offer the government the land it owns on Barren Island for this purpose.—A bill has been introduced in the Missouri legislature to provide a hospital for the State, to be known as the Missouri General Hospital. If this bill becomes a law the city will be relieved of many of the indigent sick who annually tax the institutions of the city.—The new Catholic hospital at Hot Springs, S. D., has been begun. The land was donated and some of the money was raised by subscription. It will be under the charge of the Benedictine Sisters.—A new hospital is to be built at Dobbs Ferry, N. Y., the plans for which are to be ready by March 1st, and the building to be begun by May 1st. It will cost \$12,000, which amount will be made up by residents of Dobbs Ferry.—The Sydenham Post-graduate Hospital, on West Thirty-fourth Street near Tenth Avenue, opened its doors to applicants who wished to be vaccinated. It is a non-sectarian institution and the only hospital in that section of the city.—The Southern Dispensary and Hospital of Brooklyn has been dissolved by Justice Dickey.—A bill has been passed in the Senate providing for additional buildings for the Providence Hospital at Washington.—The United Presbyterian Women's Association has decided to build a small addition to the Memorial Hospital at Pittsburgh, Pa., to relieve the crowded condition of the present building.—The Beahan Hospital has been incorporated at Rochester, N. Y. The board of directors is composed of Dr. A. L. Beahan, Dr. M. R. Carson, Dr. O. J. Hallenbeck, Dr. J. H. Jewett, Dr. F. E. McClellan, Dr. J. A. Hawley, Dr. H. C. Buell, and Dr. F. H. Warner.—There is a movement on foot to establish a Presbyterian hospital at Atlanta, Ga.—The new buildings of the Hale Hospital, at Haverhill, Mass., considered among the best in the State, were recently opened for formal inspection.—A lot containing 21,500 feet of land has been purchased for \$26,500 for the new Deaconess Hospital in Boston. Toward the amount stated \$15,000 has been pledged, \$10,000 of which is conditional upon the raising of \$30,000 before January 1, 1902.—The board of aldermen of Buffalo have voted to have plans and specifications prepared and to advertise for bids for the construction of a new quarantine hospital at a cost not to exceed \$50,000, and to ask the board of supervisors to provide a site for the hospital on the Almshouse property.—At the annual meeting of the board of directors of Lakeside Hospital, Cleveland, O., recently, the following gifts to the hospital were announced: Amos Townsend estate, \$7,850; Mr. and Mrs. J. C. Morse, \$10,000; Mr. and Mrs. H. H. Brown, \$5,000; Mr. Fayette Brown, \$30,000; H. M. Hanna, \$83,500; Mr. and Mrs. L. C. Hanna, \$10,000; J. Hartness Brown, \$5,000. In addition to this are gifts from John D. Rockefeller and L. H. Severance of enough money to pay off the balance of the debt on the new buildings, amounting to \$30,000.—The new St. George's Hospital at Kansas City, Mo., has been opened. It will accommodate 100 patients. At a special meeting of the board of health it was decided to spend \$2,000 more on the hospital and its equipment.—A fund of nearly a million dollars has been raised in the

Presbyterian church to be used for defraying church debts and erecting hospitals in the larger cities. Among the points where a hospital is to be built is St. Louis.—The West Philadelphia Hospital for Women has received \$5,000 for the endowment of a bed from the estate of Mary Baker.—The will of the late Oswald Ottendorfer, of New York, bequeaths \$20,000 to the German Hospital and Dispensary.—Senator Payne has introduced in the Illinois legislature a bill making the following appropriations for the Western Hospital for the Insane: For ordinary expenses, \$182,000; for a society hall, \$12,500; for a male dormitory, \$7,000; for a laundry, \$4,500; for a parole ward, \$7,000; for improving the grounds, \$10,000; for a refrigerator plant, \$2,500; for a library, \$500; for repairs and improvements, \$6,000.—Owing to the large number of patients constantly in St. Mary's Infirmary, Cairo, Ill., the sisters have decided to have a new building erected in the spring. Some of the older buildings will be torn down, but the large frame structure will be moved back and generally overhauled. The new addition, which will be of brick, will be erected at the rear of the present brick structure and in front of the frame.

Births, Marriages, and Deaths.

Engaged.

MUNDORFF—GRAU.—In New York, on Saturday, February 2d, Dr. George Theodore Mundorff and Miss Minnie Grau.

Married.

BLACK—STORR.—In Baltimore, on Wednesday, February 6th, Dr. R. Markley Black, of Cecilton, Maryland, and Miss Mary L. Storr.

DUKE—PERKINS.—In Kansas City, on Wednesday, January 30th, Dr. John William Duke, of Oklahoma, and Miss Isabelle Perkins.

HAY—PRICE.—In Chestnut Hill, Pennsylvania, on Wednesday, February 6th, Dr. Charles Mackenzie Hay, of Woodstock, New Brunswick, Canada, and Miss Louisa Gordon Price.

LANE—FARGASON.—In Camp Hill, Georgia, on Tuesday, January 29th, Dr. Sidney W. Lane, of Berlin, Maryland, and Miss Annie Fargason.

SAILER—STRAWBRIDGE.—In Germantown, Pennsylvania, on Wednesday, February 6th, Dr. Joseph Sailer, of Philadelphia, and Miss Mary Lowber Strawbridge, daughter of Dr. George Strawbridge.

WELTY—WOOD.—In San Francisco, on Thursday, February 7th, Dr. Cullen F. Welty, of Cleveland, and Miss Eleanor Wood.

Died.

BARKWELL.—In Tucson, Arizona, on Monday, January 28th, Dr. Wesley W. Barkwell, of Chicago.

FERGUSON.—In St. Charles, Missouri, on Wednesday, January 30th, Dr. David W. Ferguson, aged eighty-three years.

FRANKLIN.—In New York, on Wednesday, February 6th, Dr. Benjamin Franklin, in the fifty-fifth year of his age.

HUNDLEY.—In Tappahaunock, Virginia, on Wednesday, January 30th, Dr. John Hundley, in the seventy-fifth year of his age.

KENNEDY.—In Michipicoten, Ontario, Canada, on Wednesday, January 30th, Dr. James Harty Kennedy.

MELLINGER.—In Creswell, Pennsylvania, on Thursday, February 7th, Dr. Henry S. Mellinger, in the seventy-ninth year of his age.

MIDDLETON.—In Washington, on Thursday, January 31st, Dr. Rosier Middleton, of Herndon, Virginia.

OSBORN.—In Dubuque, Iowa, on Sunday, February 3d, Dr. Charles Osborn, of Clinton, Iowa.

RICE.—In Trenton, N. J., on Wednesday, February 13th, Dr. William Rice, aged sixty-three years.

Pith of Current Literature.

Lancet, January 26, 1901.

The Selective Influence of Poisons in Relation to Diseases of the Nervous System. By Dr. F. W. Mott.—The author's article deals with the primary intoxications and degenerations of the nervous system which are occasioned directly or indirectly by some general toxic condition of the blood or lymph. In a great number of instances, particular groups of neurones are especially affected by particular poisons. These poisons act by increasing or diminishing the excitability of the nervous elements. Whether a poison is exogenous or autogenous, it is the toxic state of the blood or lymph that causes the morbid nervous phenomena. Of the exogenous poisons, one great group is of those substances used as intoxicants—alcohol, opium, haschisch, cocaine, tobacco, and absinthe. The abuse of alcohol is the most widespread and potent cause of nervous and mental diseases. The various specific effects produced by the above-mentioned poisons are dealt with in detail. Poisons may be produced within the body (1) by the perverted action of the organs or tissues, and (2) by the action of micro-organisms upon the living fluids and tissues of the body. As belonging in the first class may be mentioned uræmia, cholæmia, uricacidæmia, aceto-uræmia, and the perverted state of the blood or lymph in nyxœdema and Graves's disease. The spinal sclerosis observed in pernicious anæmia are due, not to hæmolytic, but to some toxic agent absorbed into the portal blood from the alimentary canal. The best examples of the selective action of microbial toxins are afforded by diphtheria and tetanus; diphtheria, influenza and other affections may also be cited. Syphilis is a poison which is responsible for a large proportion of organic nervous diseases. It may attack the nervous system directly, or it may produce progressive degenerations (locomotor ataxia, general paralysis of the insane).

Plague. By J. M. Atkinson, M. B.—In this article the author deals with the symptoms and diagnosis of plague and the measures necessary to prevent its extension. He also discusses the *post-mortem* appearances, the clinical varieties of the disease, its bacteriology, and its diagnosis. The following is an outline of the procedure adopted in Hong-Kong in dealing with outbreaks of the plague:

1. *House-to-house Visitation.*—This is effected by officers of the local government board, and the sick and dead are removed in special ambulances. The disease is notifiable, but the Chinese universally evade the regulation.

2. *Segregation of Contacts.*—All individuals who have been in immediate contact with cases of the disease are isolated in sheds erected in various parts of the city.

3. *Isolation hospitals,* which should be made of wood, so as to be easily destroyed.

4. *Disinfection of infected premises,* by spraying with solutions of corrosive sublimate or fumigating with free chlorine gas.

5. *Latrines and sewers are kept flushed out* and disinfected as far as possible.

6. *The night-soil at the hospitals and the dressings from patients* are burned after being mixed with sawdust.

7. *Haffkine's antitoxic serum* is kept and supplied free of cost.

8. *A reward is given for each rat* brought to the sanitary authority.

A Suggested Method of Preventing Water-borne Enteric Fever amongst Armies in the Field. By Dr. L. C. Parkes and S. Rideal, D. Sc.—The authors report the results of their experimental trials of acid sodium bisulphate as a destroyer of typhoid bacilli in drinking-water. They conclude that water naturally infected with the virus of the disease never contains large numbers of typhoid bacilli, and that these organisms are not by any means resistant to acids or other weak disinfectants. Their experiments show that in the case of such naturally infected waters, sodium bisulphate in the proportion of one gramme to the pint is an effective antiseptic after fifteen minutes' contact, even for waters containing 50,000 bacilli to the cubic centimetre. They recommend its employment in the form of five-grain tabloids, three of these being used to sterilize one pint of water. A box containing three or four hundred of these tabloids can easily be carried by each soldier, and would suffice for a campaign of three weeks. But instruction must be given as to their use, and especially as to the necessity of allowing all contaminated water to remain in contact with the dissolved tabloids for at least fifteen minutes before being consumed. The tabloids may also be used as thirst lozenges when water is scarce.

Notes on Acquired Syphilis of the Nose and Pharynx. By C. A. Parker, F. R. C. S.—*Primary syphilis in the nose* is very rare. Its seat is usually on the alæ or just within the vestibule, and it is accompanied by swelling of the submaxillary glands.

Secondary syphilis does not attack the nose in any definite or serious way. The following manifestations are met with: (1) Coryza; (2) mucous patches; (3) rhinitis, erythematosa, and papulosa; and (4) superficial ulceration.

Tertiary syphilis of the nose may be met with in any of the following forms: (1) Gummata; (2) superficial ulceration; (3) deep ulceration and necrosis; and (4) scars, adhesions, and deformities.

Primary Syphilis of the Pharynx.—The primary sore occurs in the pharynx fairly frequently, usually on one tonsil.

Secondary Syphilis of the Pharynx.—1. Erythema. 2. Mucous patches. 3. Superficial ulceration.

Tertiary Syphilis of the Pharynx.—1. Gummata, (a) circumscribed, and (b) diffuse. 2. Ulcerations. 3. Scars, contractions, and adhesions.

Removal of a Foreign Body from the Bronchus by Intrathoracic Tracheotomy. By H. Milton, F. R. C. S.—The author describes a case of anterior median thoracic incision for a foreign body in the right bronchus. The patient had had a tracheotomy performed some years previously for syphilitic stenosis of the larynx, and the outer tube had fallen into the trachea. It was successfully removed, and he did well at first, but died of sepsis on the second day.

A Singular Case of Extensive Deposit of Phosphate of Lime in the Lungs. By Dr. T. Fisher.—The author reports a case in which, at autopsy, the lungs were found to be studded from apex to base with granules of phosphate of lime. Sections of decalcified portions of the lungs showed few abnormal changes. Calcification had obviously taken place in so-called amyloid bodies, and the presence of large quantities of phosphate of lime was secondary to the existence of amyloid bodies in the lungs in unusual numbers.

Notes on a Case of Poisoning by Coal-tar Naphtha. By G. H. Douthwaite, M. R. C. S.—The author reports

the case of a girl, aged five years, who took three ounces of coal naphtha and died nine days later of bronchitis. When seen, some hours after taking the naphtha, the face was dusky and livid, pupils dilated, pulse rapid and small, and respirations rapid and difficult. Artificial respiration, counterirritation, and stimulation restored consciousness, and the child did well for two days, when the bronchitis developed which proved fatal at the end of a week.

A Case of Anthrax. By A. Kidd, M. R. C. S.—The author reports a case of anthrax occurring in a man aged twenty-seven years, who was engaged in the hide trade. The whole diseased area of the neck (about three quarters of an inch square) was excised, the subjacent tissues scraped with a Volkmann's spoon, and pure phenol applied. The patient developed high fever and the neck was much swollen for a few days, after which the trouble gradually subsided and recovery took place.

Splenomedullary Leucæmia; Remarkable Tolerance of Arsenic. By Dr. C. Heaton.—The case here reported is of interest in showing how arsenic may be tolerated by these patients. The total number of days was 271, including intervals amounting to fifty-eight days, and the total amount of hypodermic administration was as follows: Arsenious acid $5\frac{1}{2}$ grains, arsenate of sodium 105 grains, and sodium cacodylate $10\frac{2}{3}$ grains. In addition, $10\frac{2}{3}$ grains of sodium cacodylate were administered orally. The maximum dose administered at one time was $2\frac{2}{3}$ grains of arsenate of sodium, equivalent to 4 drachms and 26 minims of liquor sodæ arseniatis. At no time were there any symptoms of poisoning. The influence of the treatment was beneficial for a time.

Results of Thirty-five Prophylactic Injections of the Antidiphtheritic Serum. By P. R. Blake, M. R. C. S.—Following the occurrence of three cases of diphtheria in a children's home, the author injected thirty-five children with immunizing doses of antitoxine. The amount used in each case was about 334 units. In no case did any local lesion follow at the site of injection; no other case of diphtheria ensued, and in thirty-one cases no reaction followed. In four cases, all of which were tuberculous, there were fever and glandular enlargement in two, and rash formation in the remaining two.

February 2, 1901.

Considerations Touching the Pathology and Relations of Diabetes. By Dr. W. H. Dickinson.—The author reviews the morbid anatomy of diabetes in the light of our present knowledge. The most frequent morbid appearance found in connection with diabetes is extravasation of blood in the perivascular canals of the brain, not limited to, or constant in, any one part, but scattered apparently at random around the deeper arteries and also the more minute vessels of the pia mater. These extravasations are the results of transudation and have no connection with the coma of diabetes. Such perivascular hæmorrhages indicate an abnormal condition of the cerebral circulation. Enlargement of the perivascular canals also takes place, giving to certain districts of the white matter a cribriform appearance. Leucocytes, amorphous matter, and blood crystals may be found in these canals. Dilatation of the central canal of the spinal cord occasionally occurs in diabetes. There is also sometimes to be observed a peculiar hyaline modification of the lateral parts of the gray horns. Next to the brain, the liver supplies an early step in the diabetic process. The diabetic liver is large, hard, red, and congested. The vessels are full of blood and have been

known to present coagulation both in the arteries and veins. Mention is also made of the consequential changes to be observed, such as cataract, pulmonary tuberculosis, etc.

Grief, anxiety, and terror may all be so closely followed by diabetes that there is no room for doubt as to their having occasioned it. Heredity is a prominent cause, as also is gout. The loss of the patellar reflex may be regarded as one of the most constant signs of the disease. The extravagant exit of phosphate of lime in some cases of diabetes has to do with the state of the nervous system in this disease. The peculiar dusky redness of the complexion, so often present in advanced cases, suggests a connection with the nervous system. Glycosuria in small amount accompanies insanity, not frequently, but often enough to imply a morbid relation between the two. From these facts the conclusion is reached that diabetes is not a "functional disease," and that in all probability its pathology is closely associated with that of disease of the nervous system.

Femoral Hernia. By W. H. Battle, F. R. C. S.—After discussing the diagnosis of femoral hernia from other swellings in the femoral region, and the various operations for its radical cure, the author describes his own procedure, in which he makes a shutter of the external oblique muscle, thus opposing the descent of a hernia between the sac and the canal. He has performed the operation successfully in three cases, with no recurrence so far.

The Hæmorrhagic Diathesis in Typhoid Fever and its Relationship to Purpuric Conditions in General. By Dr. A. G. Nicholls and G. E. Learmouth, B. A.—In the present communication the authors report a most extreme example of enteric fever with the hæmorrhagic diathesis. The case was that of a woman aged twenty-one years, and the first hæmorrhage (into the skin of the abdomen) was observed on the fourteenth day of the disease. Thirteen days later the patient had two intestinal hæmorrhages and multiple hæmorrhages over the trunk. The next day there was nosebleed and hæmorrhage from the lips and gums and into the conjunctivæ. These losses of blood continued and the patient died on the fortieth day of her illness. The temperature was never very high. The *post-mortem* examination showed the case to be one of typhoid fever atypical in the particulars that the intestinal lesions were most marked in the large bowel, that the spleen was small, that there was a general hæmorrhagic diathesis, and that there was a mixed infection with the *Staphylococcus albus*. One main factor of the extensive hæmorrhages was the fatty degeneration of the basement membranes of the capillaries, which was specially noticeable in the lungs and the kidneys. The authors refer this fatty degeneration, not to any local action of bacteria, but to a condition of systemic intoxication and septicæmia. They have studied the literature of hæmorrhagic typhoid, and discuss its pathology, symptoms, prognosis, and treatment. The cases fall into three groups: (1) primary typhoidal purpura; (2) purpura due to secondary bacterial invasion; and (3) cachectic purpura. The condition is generally very grave and the treatment is purely symptomatic. "Purpura hæmorrhagica" is to be looked at as a train of symptoms. In the light of our present knowledge, it would be better to speak of (1) an "essential" purpura, including morbus Werlhofii, purpura simplex, purpura urticans, etc.; (2) "symptomatic" purpura, including all those cases met with in the course of the infective fevers; (3) "cachectic"

purpura, as seen in Bright's disease, pernicious anæmia; 4) "toxic" purpura, due to snake-bite, poisons, etc.; and (5) that form of purpura seen in disseminated sarcomatosis. The first two groups, and possibly the third, would fall under the head of "infectious" purpura.

The Treatment of Typhoid Fever. By Dr. F. J. Smith.—In the treatment of typhoid fever two principles are of overwhelming importance: these are (1) the examination (daily) of the stools; and (2) the appetite of the patient. 1. In the stools may be found (a) undigested milk or other food, showing that too much food is being given; (b) blood, which, if present in any quantity, calls for the administration of opium; (c) mounds, the total bulk of which indicates the amount of ulceration; and (d) fæculent *débris*, the desirable constituent of the stools. 2. The appetite of the patient should be, within very wide limits, the sole arbiter of his diet, provided vomiting, hæmorrhage, or distension are all absent. The temperature is entirely ignored. Where the appetite is good a wide range of dietary is allowed; where there is no appetite, the best food is plain cold water. The author has kept patients for days on nothing but water, with the best results. On the first indication of nausea after food, resort should be had to the plain water diet for twelve hours. Tympanites is an ominous complication and most difficult to treat. The author gives two drachms of sulphate of sodium every two hours until the bowels are acting freely. Constipation should never be allowed to persist. Excessive diarrhœa points either to too much food or to extensive ulceration of the colon. The occurrence of hæmorrhage calls for starvation and opium. Alcohol is unnecessary for the treatment of typhoid fever. The author believes that antiseptic inoculation is destined to be the universal method of treatment and prophylaxis in typhoid fever.

Filatow's Spots in Morbilli. By Dr. L. Falkener.—The author's observations are based upon seventy-six cases of measles, in all of which he found Filatow's or Koplik's spots. Their commonest site is the buccal mucous membrane, opposite to, and on a level with, the bases of the lower milk molars. They were seen in patients of all ages. In no case were they seen before the third day preceding the eruption. On the day before the eruption, and on the day of the eruption, they were seen in every case. They disappear with great rapidity and are usually gone by the third day of the exanthem. Aphthous stomatitis furnished the only great difficulty in diagnosis. The author examined some 3,000 cases other than measles for the spots, but never found them. The spots are of the greatest utility as a definite means of diagnosis in röteln, measles with laryngitis simulating laryngeal diphtheria, measles without eruption, and nitroline rashes and erythema multiforme.

Laparotomy and Cleansing of the Peritonæum in a Case of Tuberculous Peritonitis. By Dr. G. W. Davis.—The author reports a case of tuberculous peritonitis with extensive fibrous areolæ occurring in a girl aged seven years, in which laparotomy and douching of the peritoneal cavity with normal saline solution brought about marked improvement in every way.

Selenium Compounds as Factors in the Recent Beer-poisoning Epidemic. By Dr. F. W. Tunnicliffe and J. Rosenheim, Ph. D.—In connection with the recent beer-poisoning epidemic in England, the authors have been struck with the apparent incongruity between the doses of arsenic taken and the effects produced. They suggest that some tangible poisonous substance has found its way into the beer along with the arsenic.

Selenium at once suggested itself; it occurs in nearly all pyrites and the acids prepared from them, and its compounds are highly poisonous, producing symptoms practically identical with those produced by arsenic.

An Intra-peritoneal Method for Radical Cure of Inguinal Hernia. By Dr. T. H. Wells.

A Case of Primary Carcinoma of the Vermiform Appendix. By T. R. C. Whipham, F. R. C. S.—The author reports a case of primary carcinoma of the vermiform appendix, occurring in a woman aged forty-five years. The affection is not quite so rare as has been supposed; the reasons why cancer of the appendix have been overlooked are: (1) that appendices after removal are not submitted to microscopical examination as a routine practice; and (2) that in dissemination of the disease the appendix may be involved in a large mass of growth implicating the cæcum or other parts which may be thought to have been the seat of origin of the affection.

British Medical Journal, February 2, 1901.

The Complications of Gastric Ulcer and their Treatment. By A. W. Mayo Robson, F. R. C. S.—In this article the author deals with some of the simple diseases of the stomach associated with ulceration, which are capable of relief or cure by surgical means. He classifies the various forms of gastric ulcer as follows: I. Erosions: (a) simple erosions; (b) exulceratio simplex, of Dieulafoy; this form of ulceration may give rise to severe hæmorrhage, which may rapidly prove fatal unless arrested by treatment. II. Simple ulcer: (a) acute round ulcer, most often found in chlorotic young women; (b) chronic ulcer, the form which most frequently gives rise to complications. After discussing the questions of symptoms, diagnosis and the advisability of exploratory operations, the author states that the treatment of gastric ulcer is at first essentially medical, and if properly carried out and for a sufficient length of time, is usually completely successful. Where surgical intervention becomes necessary, gastro-enterostomy, of all operations, is the one to rely on. The author prefers the posterior operation, the junction of the stomach and first part of the jejunum being effected by two continuous sutures around a decalesified bone bobbin. His last twenty cases have all recovered without pain or any drawback. Perforation is one of the most serious complications, and occurs in about fifteen per cent. of all cases of ulcer of the stomach. Doubtless many perforations are recovered from, if the accident happens when the stomach is empty. Statistics clearly prove that operation for perforation of gastric ulcer, if undertaken within a few hours of the accident, is very hopeful; but that death occurs in more than half the cases when operated on after twenty-four hours. Hæmorrhage occurs in eighty per cent. of all cases of gastric ulcer; surgical treatment should be adopted in recurring acute, as well as chronic, hæmorrhage. Cicatricial contraction of the pylorus is the complication of gastric ulcer which most frequently calls for surgical treatment; where active ulceration is going on, gastro-enterostomy is the best operation. In cases of hour-glass contraction of the stomach, the operation of gastroplasty has given excellent results. The adhesions formed in cases of perigastritis complicating gastric ulcer often call for surgical treatment; this operation the author terms "gastrolysis."

A Case Illustrating the Relief of Chronic Gastric Disease by Gastro-enterostomy. By A. E. Barker, F. R. C. S.—The author reports a case that illustrates in a striking way the benefits of surgical intervention in

chronic pyloric stenosis. The patient, a woman aged forty-two years, had led a miserable life of pain and distress for years, and had reached the last stage of weakness. A diagnosis of non-malignant pyloric stenosis due to contraction after ulcer was made, and a gastro-enterostomy performed. Her recovery was uneventful and rapid; she gained over thirty pounds in weight in a few months and has remained perfectly well in every way.

Remarks on a Case of Retroperitoneal Cyst. By Dr. S. W. Cousins.—The author reports a case of this affection occurring in a married woman; the cyst had caused no pain and but little inconvenience, the patient thinking herself pregnant for months. Laparotomy was performed and six pints of a clear and slightly yellowish fluid were removed by aspiration. The fluid was clear, alkaline, and very slightly colored; specific gravity, 1.020; a few blood and pus cells. The cyst was fixed to the lower angle of the abdominal wound and a drainage tube left in for two weeks, after which the wound rapidly healed. The report is accompanied by some general remarks on the causation, symptoms, and diagnosis of retroperitoneal cysts.

Strangulated Femoral Hernia; Successful Primary Resection of the Damaged Gut. By H. B. Robinson, F. R. C. S.—In reporting the case, the author draws attention to the following points: 1. The accurate apposition of the mesenteric border of the cut ends of the intestine was attained by the stitch similarly used by Maunsell in his method of resection. 2. The adoption of a continuous Lembert's suture, whereby the sutured edges are more evenly supported and much time is saved. 3. The resection *in situ*, instead of making an abdominal incision, withdrawing the damaged gut and running the risk of fouling the peritoneal cavity.

The formation of an artificial anus is thus avoided, together with the necessity for a secondary operation, and there is a great saving of time.

Some Remarks on the Radical Cure of Hernia; Based on 190 Cases of Operation for the Cure of Oblique Inguinal Hernia. By A. R. Anderson, F. R. C. S.—The operation now performed by the author is the Bassini-Halsted, with some slight modifications. Under this method he has not had a single relapse that he knows of. The operation is attended with a very low death rate. Of his 190 cases, four died, in two of which strangulation existed. The ages of the patients varied from one to over seventy years. Silk sutures were used in the last sixty operations, without the occurrence of suppuration in one of them. The author never orders a truss to be worn after the operation. Where cleanliness and good truss management cannot be obtained, he does not hesitate to advise operation in children under four years of age who are otherwise healthy.

Carcinoma of the Liver at the Age of Twenty-four Years. By Dr. D. McKenzie.—The remarkable feature of the case of carcinoma of the liver here reported is the youth of the patient—twenty-four years, when the illness commenced. The diagnosis of carcinoma, as opposed to sarcoma, was arrived at upon consideration of the chronic afebrile character of the illness and the bony, hard, and general enlargement of the liver. No autopsy was obtainable.

Remarks on Aneurysm of the Coronary Arteries of the Heart. By Dr. T. W. Griffith.—The author reports two cases of aneurysmal dilatation in the course of the coronary arteries, discovered at the *post-mortem* examinations. He has collected from the literature of the subject twenty-four such cases, the earliest of which was

published in 1812. In seven instances the aneurysms were multiple. In only two instances was the aneurysm in the auricular wall; in all the others it appears to have been on the main stem of the artery or on the ventricular part of the heart. In fourteen instances the affection occurred in the male sex. It is a well-recognized fact that embolism plays a very important part in the causation of aneurysm, especially in the smaller blood-vessels. But the exact way in which embolism gives rise to aneurysm is not yet definitely settled. The author inclines to the view of Goodhart, who points out that most embolic aneurysms are associated, not with a simple endocarditis, but with an ulcerating form of the disease, a very severe form, generally producing fever and septic conditions. The clot from such a part will lead to acute softening of the arterial wall by inoculating it with its own inflammatory characters.

Revue de médecine, November 10, 1900.

Paludism and General Paralysis.—M. E. Marandon de Montijal concludes from his study of several cases that acute paludism may occasion progressive general paralysis or general pseudo-paralysis in those who are predisposed to it. Chronic paludism may not only evoke the second disease in those disposed to it, but may ever furnish a basis for paresis in those who are not disposed to it. Paludism may cause an early appearance of paresis, and the course of the latter is usually rapid.

Heroine for Morphine in Morphinism. By M. A. Morel-Lavallée.

Wound of the Left Vertebral Artery; Hæmorrhachis; Compression of the Cord. By M. Bouchaud.

Presse médicale, January 2, 1901.

Visceral Atrophy and Arterial Hypoplasia.—M. Emile Sergent reports a case of general atrophy of the viscera, especially of the heart and spleen and of the great blood-vessels. Fatty degeneration of the liver and ulcerations of the intestines were also found. The author attributes the visceral smallness to the diminished caliber of the aorta and its principal branches, although he believes the atrophy to have been congenital and not consecutive to the arterial hypoplasia. Yet the arrested development of the viscera is due to the vascular condition.

January 5, 1901.

Treatment of Eclampsia.—M. Gaulard reviews the well-known methods of intervention in threatened or existing eclampsia of the pregnant woman. He himself favors intervention in order to save the life of the mother, while waiting for a length of time sufficient, if possible, to save the infant's life also; but the life of the mother must first be considered. Embryotomy is indicated if it is necessary. The author thinks symphysiotomy offers too great a mortality at present to be a routine measure.

Distribution of Leprosy in Indo-China and Yunnan. By M. E. Jeauseline.

Lyon médical, January 13, 1901.

True Bones of the Lung. By M. Devie and J. Paviot. (*Continued article.*)

Deaf-mutism.—M. A. Rivière says that not infrequently thyroid absence and the presence of adenoid vegetations are found in the same individual; likewise that deaf-mutism and thyroid absence appear together geographically. Acting on theoretical grounds, he is

cured two cases of deaf-mutism by removal of adenoid growths, Politzerizing the drums and giving thyreoid extract simultaneously, for a period of months. The patients were brothers, both young children, and were congenitally deaf-mutes.

Progrès médical, January 12, 1901.

Socalled "Pernicious Gastric Fever."—M. Jean Cardamatis and M. S. Kanellis say that this name should be abandoned, since the disease rarely ends in death, and because the treatment is by quinine in the same dosage as in simple intermittent fever, which is probably the most frequent, if not the only, source of the disease. Paludism can usually be demonstrated in cases of "gastralgie" fever. The gastralgie is only a symptom of a masked malarial infection, it is a simple complication of malaria and should not be dignified by a name of its own.

Indépendance médicale, January 16, 1901.

Black Appendicular Vomiting.—M. Dieulafoy describes a case of melæna in which œsophageal and gastric lesions were excluded. The man was fed by the rectum and finally recovered. He reports a number of similar cases in which hæmatemesis followed, and sometimes preceded, operation for appendicular inflammation. He desires to make a special group of these cases with the above title, since they are characteristic of a particular form of appendicular inflammation.

Gazette hebdomadaire de médecine et de chirurgie, January 13 and 17, 1901.

Grippal Polyneuritis. By M. Dienier.—An abstract.

Note upon the Hæmatocrite.—M. M. H. Mallet, writing of Deland's hæmatocrite, says that it can be employed to estimate the number of red cells in normal blood in counting cells where an error of more than 100,000 is possible. In pathological cases where a possible change in form or diameter of the red cells may exist, it is not so trustworthy; but when used comparatively with the hæmatometer, it can give useful clinical results as to the average diameter of the red cells.

Deutsche Aerzte-Zeitung, January 15, 1901.

When to Operate in Perityphlitis. By Professor Köste. (*Continued article.*)

Bacteriological Blood-examinations in Phthisis.—Dr. A. Lasker concludes that in cases of phthisis the presence of tubercle bacilli in the blood can only rarely be demonstrated. When they are found, the patients are, as a rule, in the last stages of the disease. The bacteria in the blood cannot, therefore, be taken to account for the fever of phthisis patients.

Internal Treatment of Gonorrhœa. By Dr. Martin Friedländer.

Treatment of Syphilis. By Dr. Max Joseph.—A review of the literature.

Centralblatt für Gynäkologie, January 5, 1901.

Umbilical Hernia with Resection of Prolapsed Lobe of the Liver.—Dr. Otto Küstner reports an operation of this kind upon a newly born child which died nineteen days later of melæna. The liver was then found to be inseparably connected with the abdominal wall.

Protargol instead of Silver Nitrate for Infants' Eyes.—Dr. Fritz Engelmann says that protargol has

failed to take the place of nitrate of silver as a prophylactic measure against gonorrhœal ophthalmia, because its stability is not so great. Either no reaction appeared or it was much more severe than is usually seen from the use of nitrate of silver.

Hypertrophy of the Female Breast. By Dr. A. Grasmück.

Centralblatt für innere Medicin, January 5, 1901.

Histologic Changes in the Central Nervous System and the Stomach in Tetany of the Stomach. By Dr. L. Ferrannini.

Auscultation of Normal and Pathological Muscle.—Dr. Max Herz says that auscultation over contracting muscles elicits a sound very similar to that given by the first sound of the heart. It may be divided into three parts: the muscle-tone, preceded by a musical sound and followed by a sort of murmur. These conditions are changed by disease, as in a case of Thomsen's disease, in which the last sound only was heard after the muscle had completed its contraction. The author goes minutely into the characteristics of the three sounds and believes the phenomenon will attain clinical significance.

Berliner klinische Wochenschrift, December 26, 1900.

Flechsigs's Opium-bromide Cure.—Dr. E. Meyer and Dr. C. Wickel make a report upon Ziehen's modification of Flechsigs's cure of epilepsy, which consists in limiting the amount of opium to twelve grains of that drug daily, and insisting upon the use of large quantities of the bromides for at least one year. A rigid diet and hydrotherapy are combined with these measures. In contrast to the cases treated with bromides alone, they find the seizures diminished and the physical and psychic conditions of their patients decidedly improved.

Treatment of Nervous Cases at Home. By Dr. R. Gnauck.

Treatment of Septic Infections Arising from the Uterus.—Dr. Abel repeats Brunner's bacteriological classification. He thinks uterine irrigations with lysol or bichloride of mercury solutions useful, and does not speak disapprovingly of Carossa's plan of alcohol irrigation. He regards atmokausis as a practical disinfecting method. He does not favor general extirpation of the uterus, unless no pyæmic evidences are present. He thinks it justifiable to extirpate the uterus if no pathogenic germs are found in the blood, but some are present in the uterine cavity. The author mentions the other well-known measures of treatment, including the use of Marmorek's serum and Fochier's *abcès de fixation*. He cordially recommends saline infusions and oxygen inhalations as important adjuvants of treatment.

Sensitiveness of the Modified Phenylhydrazine Test for Urinary Sugar. By Dr. Albert Kowarski.

Consideration of Forensic Nervous Diseases (conclusion). By Dr. A. Cramer.

Wiener klinische Wochenschrift, January 3, 1901.

Curative Effects of Local Hyperæmia.—Dr. Karl Ullmann describes the results obtained from the local use of hot air in ulcers and infectious sores (chancres, chancroids, etc.). In a large number of cases a perfect cure was obtained, in others a decided amelioration of the condition. The good effects are due, undoubtedly, the author thinks, to the local hyperæmia induced by the heat. Venereal and varicose ulcers yielded especially well to the treatment.

Permeability of the Intestines to Bacteria. By Dr. Hugo Marcus.—A polemic article.

Case of Pemphigoid Measles Complicating Diphtheria.—Dr. J. Zuhr reports a fatal case of diphtheria complicated by measles, with an eruption which assumed the characters of pemphigus. The vesicles of the pemphigus eruption appeared only upon the measles spots.

Medicinisch-chirurgisches Central-Blatt, January 11, 1901.

Artificial Feeding of Infants. By Dr. B. Bendir.—A theoretical paper.

Some Inflammatory Diseases of the Female Pelvic Organs.—Dr. G. Weidenbaum writes that his results at Kemmera (a bathing resort in Russia) in 200 gynecological cases have been very satisfactory when combined with "moor" baths, tampons, and massage. Inflammatory tumors are rapidly absorbed, menstruation becomes regular, hæmatocœles and inflammatory conditions of the tube gradually disappear or become smaller, sleep is promoted, and pain is quickly relieved.

Klinisch-therapeutische Wochenschrift, January 13, 1901.

New Therapeutic Methods in Nervous and Mental Diseases. By Dr. Ladislav Hascovec.

The Active Agent in Radiotherapy. By Dr. E. Schiff and Dr. L. Freund. (*Continued article.*)

Treatment of Convulsions in Children.—Dr. Jacob Götz advises an enema of a quart to a quart and a half of physiological salt solution. At the same time from seven and a half to twenty-two grains of chloral hydrate are given by the rectum, and the child is then placed into a mustard bath until its skin becomes red. Care must be taken not to get any of the mustard water into the child's eye. The child is thoroughly dried, rubbed, and put to bed. It soon perspires freely and falls asleep. If the convulsions are due to teething, the author incises the distended mucous membrane of the gum.

Wiener medicinische Blätter, January 10, 1901.

The Treatment of Empyema.—Dr. Edward Martin says that the prophylactic treatment of empyema consists in emptying at once every considerable pleural effusion of inflammatory origin. In this little operation the skin should always be cut with a scalpel at the point where the exploratory needle is inserted. Serous effusions are best removed by means of aspiration; if they reaccumulate after three aspirations, they should be subjected to continuous siphon-drainage. Fresh empyemata are best treated by continuous siphon-drainage, a tube the thickness of the little finger being introduced through the cannula. If this is not sufficient, a resection of a rib must be undertaken. Delorme's operation, the removal of the pseudo-membranes from the pulmonary surface, may be necessary if the lung does not expand; and if this is impossible of performance, Estländer's operation, or Schede's operation (removal of the chest wall with the thickened pleura), must be done.

Zeitschrift für Geburtshilfe und Gynäkologie, December, 1900.

Pathology of Tumor Formation in the Female Genitals.—Dr. Hans Wülfing describes an interesting case in which the entire developmental sphere of the Wolffian

body was included. The patient had a carcinoma of the cervix, several intramural fibroids, bilateral adenomyomata of the uterine horns, and enlarged iliac glands which the author attributes to division of parts of the Wolffian body. He offers no suggestion as to the ætiology of these multiple tumors, although he hints at their common embryological origin.

Tubal Pregnancy with Simultaneous Uterine Pregnancy.—Dr. Willi Straus reports such a case in which a positive diagnosis was made before operation on account of the disproportionately large size of the uterus which corresponded to a three months' pregnancy. The diagnosis was confirmed at the time of operation. A month later the patient aborted the uterine foetus. The author reviews the literature of similar cases.

Glands, Cysts, and Adenomata of the Myometrium in Adults. By Dr. Robert Meyer. (*Continued article.*)

Tuberculosis of the Female Genitals. By Dr. Osca Polano.

Thrombosis and Embolism after Operations for Myomata.—Dr. Georg Burckhard reports three such cases, and emphasizes two points. The first lies in the fact that the usual view of cardiac degeneration as secondary to the presence of myomata, is probably incorrect, and that the changes in the heart muscle are probably primary. The second point is the emphasis of Mahler's sign of embolism, an exceptionally rapid pulse without a corresponding rise of temperature. This sign was present in every one of the author's cases.

Significance of Vaginal Germs in Obstetrics.—Dr. Sticher says, in a preliminary communication, that the methods of the future in combating puerperal infection will lie in the directions of asepsis and antiseptics. Asepsis will be best achieved by the employment of sterilized rubber gloves, while antiseptics will be accomplished by suitable preliminary preparation of the external genitals and the genital canal of the patient. The latter element cannot be considered to have been satisfactorily accomplished as yet.

Operative Treatment of Prolapse of the Uterus. By Dr. Arnold Christiani.

Riforma medica, December 27, 1900.

Concerning Pleuritic Urticaria. By Dr. D. Gomez.—The author reports a case of staphylococcal pleurisy with subacute course and serofibrinous exudate in which there appeared an urticaria during the absorption of the exudate. This form of urticaria has been termed Carageorgiades *urticaria pleuritica*. The trunk, the abdomen, and the anal folds are the most frequent sites of the eruption, which consists of wheals of various sizes. In some regions the eruption is so confluent that there is no healthy skin to be seen. The appearance of this urticaria is a favorable prognostic sign, especially if the eruption appears early and in abundance. As regards its origin, Carageorgiades attributes it to the pleuritic toxins, and looks upon it as a toxic urticaria. Rumford, in 1892, called attention to such cases, but they are quite rare. In the case reported here the patient was a girl aged sixteen years, who showed a marked urticaria during the stage of absorption of the effusion. There were no intestinal disturbances at the time. The eruption disappeared in a few days, and with it the pleuritic exudate.

December 28, 1900.

Cardiopsis; a Clinical Lecture. By Dr. G. Rumford.—This clinical entity, first described by the author,

due to a weakening of the means of support and suspension of the heart. He presented three patients, the first of whom had simple cardiopoptosis, *i. e.*, without any complications or concomitant lesions; the second presented, in addition to the sagging of the heart, a mitral stenosis of congenital origin; and the third showed, in addition to cardiopoptosis, also a splanchnoptosis, *i. e.*, a prolapse of the abdominal viscera. The heart is suspended principally by the great vessels, as well as by the ramifications of the pulmonary artery and veins in the lungs. The principal support of the heart, however, is the diaphragm, the normal position of which depends upon the abdominal pressure as well as upon the negative pressure of the chest and the aspiration of the lungs. Other means of suspension are the pericardium, which forms a sort of cuirass, holding the heart muscle in place; the sternopericardial ligaments, the aortic arch, and, finally, the other structures surrounding the heart, such as the lungs, the mediastinum, and the aponeurotic fascia of the neck. Various causes may contribute to the displacement of the heart downward. Thus, an increase of the heart muscle in volume and weight; an increase in the thoracic pressure, or a diminution in the intra-abdominal pressure. Finally, the great vessels which suspend the heart may become weakened and less resistant as the result of acute and chronic inflammation. It is true that in some grave cases of atheroma there is no cardiopoptosis, but this is because, instead of becoming weaker and more easily stretched, the arteries become rigid with the sclerotic changes. There are cases in which the arteries are congenitally lacking in elasticity, and in these cardiopoptosis will always be found. The diagnosis of this condition can only be made by physical examination. The treatment consists in the observance of hygienic rules, and in the application of some support to the diaphragm, with the use of strychnine, nux vomica, ergotine, hydrastis canadensis, or other tonics.

Vratch. December 23, 1900 (January 4, 1901, N. S.).

On the Physiology of the Cœliac Plexus. By Dr. L. V. Popelsky (*continued*).—It may be assumed, perhaps, that the occurrence of diarrhœa and gastro-intestinal hæmorrhages in the dogs whose cœliac plexus had been removed was due to the section of the splanchnic nerves, which is followed by dilatation of the intestinal capillaries and by cessation of the muscular functions of the intestines. In order to test this, the author excised about two centimetres from each splanchnic nerve in two dogs. The results showed that the hæmorrhage and the diarrhœa were not due to section of the splanchnics, but to excision of the cœliac plexus, for in these two dogs there were no such manifestations. The author concludes as follows concerning the physiological functions of the cœliac plexus: The hæmorrhages in the digestive tract are extravasations of blood from the blood-vessels of the stomach and intestines, due to the absence of the vasomotor centres which are situated in the cœliac plexus. These centres are in communication with those of the medulla by means of the cœliac nerves, but are independent vasomotor centres whose activity is destroyed by the removal of the cœliac plexus. Further, the cœliac plexus possesses independent centres, which influence the peristaltic activity of the intestines. Section of the splanchnics alone does not influence peristalsis. Excision of the cœliac plexus, also, is followed by evacuations resembling those of acholia, and this is due to the rapidity of

the passage of the fæces through the intestines, which is such that the contents have not time to become influenced by the bile. The origin of the ulcers found in the dogs in which the cœliac plexus had been removed may be explained thus: The great dilatation of the blood-vessels in the region after excision of the plexus is followed by a corresponding rise in the blood-pressure (?) in this part of the body. As a result, there are numerous effusions of blood, and the weaker vessels of the mucosa give way and rupture, and ulcers result. The author thinks that it would be well to study the condition of the cœliac plexus in round ulcers of the stomach. The clinical picture resulting from excision of the cœliac plexus in dogs reminds one of several pathologic conditions in man. Thus, for example, of cholera and typhoid fever; in fact, a number of investigators have found changes in this plexus in persons who had died of these diseases. We know also that burns of the skin may give rise to ulcers in the stomach or the upper part of the intestines. Experiments on animals have shown that even slight burns may cause extensive lesions in the plexus. The cœliac plexus is without doubt the central station for all the sensory impulses coming from the mucous and serous membranes in the abdomen. From the plexus, these impulses are conducted to the central nervous system by means of the sympathetic chains.

Journal Akouscherstva i Gienskich Boliesney, October, 1900.

The Surgical Treatment of Cancer of the Uterus.

By Dr. D. Ott.—This is a report read before the recent International Medical Congress in Paris. The report is based upon one thousand cases collected from the data furnished by a number of Russian gynæcologists, and upon two hundred cases observed by the author himself. As regards the operation to be employed in cases of cancer of the uterus, he says that most gynæcologists agree that total hysterectomy is necessary, and that amputation of the cervix is not radical enough, even if the cancer is limited to the neck of the womb. Whether, in addition to hysterectomy, the operator should also remove the pelvic and retroperitoneal glands, subjecting the patient to coeliotomy for this purpose, is another question. The fact that patients have died of metastases after successful hysterectomy for cancer, seems to show that the removal of the lymph nodes is necessary. Yet we always run the risk of leaving some glands that have escaped observation, and the operation is infinitely more dangerous when the glands are removed than when simple hysterectomy is performed. The question will remain open for discussion until the advocates of the new method have shown that their mode of procedure gives better results than simple vaginal excision of the womb. The mortality immediately after the operation is given, by Russian observers whose opinions the author has collected, as ten and three tenths per cent. In the author's clinic this percentage was reduced to one and seven tenths per cent. The number of radical cures reported in the 1,000 cases analyzed was 30, the number of years during which there was no reappearance of cancer varying from five to ten years. As only about one quarter of the cases collected were operated upon more than five years ago, this figure (30) must be referred to 250 cases. In the author's clinic 62 cases out of a total of 181 were operated upon more than six years ago. Of these, 47, or 75.8 per cent., were cases of cancer of the cervix, and 15 of adenocarcinoma. Radical cures were reported in 18 out of 62 cases: in all the others there was either a

reappearance of cancer, or they disappeared from observation. Of the 47 cases of carcinoma, 11, or 23.4 per cent., were cured radically, while in the 15 cases of adenocarcinoma, 7, or 47 per cent., recovered completely.

Intra-uterine Injections in the Mud-bath Treatment of Diseases of Women. By Dr. D. A. Parascheff.—The author points out the fact that no effect on the mucosa of the uterus can be produced by mineral mud-baths, whereas these baths have a beneficial effect on the course of diseases of the female generative organs which involve the substance of these organs and not their mucosa. He therefore suggests that the use of systematic uterine irrigation, according to the method first described by Grammatikati, be combined with the administration of mud-baths.

Post-partum Ulcers in the Vagina and in the Cervix. By Dr. G. L. Davidoff.—The author thinks that it is difficult to agree with Schroeder as to the rule that no examination with the speculum should be attempted after labor. It depends whether the physician himself has attended the labor from the first, or is only called upon to take care of the patient *post partum*. If the latter is the case, and if the presence of ulcers is suspected, nothing but an examination with the vaginal speculum will solve the question.

A Case of Multiple Pregnancy. By Dr. N. E. Akatzatoff.—The patient was a multipara aged thirty-six years, who was found in an attack of eclampsia and was delivered of triplets. The woman recovered, and the first child survived, but the other two lived but a few days.

Transplantation of the Ureters into the Rectum. By Dr. A. P. Jachontoff.—The author experimented on a series of animals in which he performed transplantation of the ureters. Of the ten dogs in which the operation was performed, six died, one disappeared from observation, and three remained alive. The causes of death were, peritonitis in three dogs, apparently shock in one, and renal complications in three. Further experiments are necessary to show whether this operation can safely be performed in man.

Demonstration of a Specimen Showing the Nerves of the Uterus. By Dr. N. N. Djonk.

Habitual Abortion and Habitual Premature Labor. By Dr. S. S. Cholmogoroff.—The causes of the abortion or miscarriage habit are very numerous, and the author reviews the opinions of the various authorities on the subject. The author uses antisiphilitic treatment in the doubtful cases where no cause can be discovered and where there are no evidences of syphilis. It is possible that the patient or her husband conceals the existence of syphilitic infection, or the woman may have had syphilis in such a light form as to be unnoticed. It is also possible that mercury and the iodides have a beneficial effect on the predisposition to abort, for in the eighteen years during which the author has used antisiphilitic treatment in these cases, he has seen very good results. He reports forty-nine cases, in five of which there was a history of syphilis, the infection having taken place at the same time as fecundation. In five other cases the husbands of the patients had had syphilis when they were single, but no syphilitic manifestations after marriage. In one case there was hereditary syphilis, and in the remaining thirty-nine cases the patients and their husbands absolutely denied syphilis. In these cases the author used mercury and the iodides in various modes of administration whether there was syphilis in the history or not. (To be continued.)

Concerning the Technique of the Operative Treatment of Prolapse of the Uterus. By Dr. N. N. Michailoff.—The author's purpose was to simplify the existing methods of operation in prolapsus uteri. The method of Hegar and Martin are certainly effective, but they are very troublesome to execute. The author came upon this new method accidentally. In operating in a case of almost complete uterine prolapse he found that the narcosis was very unsatisfactory, and that he had to hurry the operation. He had already amputated the cervix and was about to perform anterior and posterior colporrhaphy; but the catgut which had been prepared proved useless, as it tore upon slight tension. He sewed the cervix with silk threads, leaving long ends, and abandoned the idea of performing colporrhaphy. Then it was that he remembered Stoltz's method, and decided to employ the latter's idea, but without excising a flap. Accordingly, he made an incision in the anterior vaginal wall, occupying its upper two thirds. Grasping the edges with bullet forceps, and separating them, he quickly introduced his finger and raised the upper layers of tissue. The base of the fold thus raised was sewn with silk, and the edges of the incision closed with a few stitches. As a result there were two thick projections of tissue hanging down in front of the uterus, and almost occluding the lumen of the vagina. The period of postoperative observation was brief, but the patient apparently did very well. A second case was also operated upon in the same manner with satisfactory results. The author presents his method for consideration and for further clinical testing. He adds that in women who have passed the menopause, the whole vagina may be occluded by suturing the summits of the vaginal projections formed by this operation. The fate of these projections is problematic, as the patients could not be observed for a sufficient length of time, but their mechanical efficiency shelves upon which the uterus rests could not be doubted in the cases operated upon by the author.

Concerning the Duration of Pregnancy, Labor, and the Puerperium in Young Primiparæ. By Dr. N. P. Mariantchick. (Continued).

Miscellaneous.

A New Operation for the Treatment of Internal Hæmorrhoids in Ambulant Patients without Dilatation of the Sphincter or Anæsthesia.—Dr. Charles G. Levison (*Occidental Medical Times*, September, 1900) thus describes an operation, based upon purely surgical principles, which, he says, while causing some pain, is practically a radical cure and can be carried out in one or two sittings. In the average case, there is usually one varix, seldom two, which cause most of the disturbance; and these can usually be treated in one sitting. The only pain experienced by the patient is when the pile is ligated; this can be done very quickly, so that the pain is of the shortest duration. The only special apparatus required is the Kelly sphincteroscope. With this instrument every portion of the sphincteric region can be perfectly examined without reflected light and without material inconvenience to the patient. The patient is placed in the knee-elbow position and the sphincteroscope is introduced, permitting thorough inspection. After the localization of the pile or piles, a piece of cotton saturated with a ten-per-cent cocaine solution is applied for a few minutes; the cocaine does not produce absolute anæsthesia, but it diminishes pain to such a degree that patients do not object. The pile is then grasped with a Péan hæmostatic forceps and pulled down. Coincident with the drawing down of the pile

the speculum is removed from the anus; it is allowed to hang on the handle of the hæmostat, and, possessing considerable weight, aids in drawing the pile somewhat further out of the anus. The pile is now extruding, held by the forceps, which are weighed down by the speculum; it is then ligated with a silk ligature as near the base as possible, after which the forceps and speculum are removed and the ligated pile is returned to the rectum. The patient's bowels must move daily; he experiences no inconvenience going about as usual. The pile desiccates and a practical cure results. If multiple varices are present, the operation is repeated; but one sitting and the ligation of one group of varices in the majority of cases usually suffice.

Letters to the Editor.

SEXUAL INTEMPERANCE.

126 EAST TWENTY-NINTH STREET,
NEW YORK, February 1, 1901.

To the Editor of the New York Medical Journal:

SIR: A great deal could be said *pro et contra* in regard to the article of Dr. Jennie G. Drennan in your issue for January 5, 1901, entitled Sexual Intemperance. Allow me only to call attention to certain positive facts which the author might have considered, or at least mentioned, in writing the article: Some of the author's arguments are the very same which the Turks apply to justify polygamy; others are in strict contradiction to teachings of St. Paul in his first epistle to the Corinthians, and also to the teachings of the fathers and other recognized theologians of the Christian church. In other points the author's views correspond exactly with views laid down in the writings of Catholic theologians, as, for instance, in a chapter on matrimony: *Illicitus est conjugii usus, si fiat ob solam voluptatem, i. e., alios fines expresse excludendo. Patet ex propositione 9. ab Innocentio XI damnata, quæ sic sonat: Opus conjugii ob solam voluptatem exercitum omni penitus caret culpa ac defectu veniali. Per se tamen esset tantum veniale peccatum, quemadmodum veniale est, cibum ob solam delectationem sumere.* These words correspond exactly with some in the article on Sexual Intemperance in your journal.

A. ROSE, M. D.

232 EAST SEVENTY-EIGHTH STREET, NEW YORK.

To the Editor of the New York Medical Journal:

SIR: Such exaggerations and errors as those contained in the article of Dr. Jennie G. Drennan on Sexual Intemperance, which appeared in the *New York Medical Journal* for January 5, 1901, being likely to do more public harm than good, should not be allowed to remain without contradiction. The quintessence of this article seems to be that married men should abstain from sexual intercourse with their wives during the entire period of pregnancy and lactation, *i. e.*, for various periods of almost two years each. I am sure that it is not the intention of the authoress to have men satisfy their *libido sexualis* during these periods with individuals other than their own wives, she insisting, apparently, upon total abstinence. I think it would be mere hypocrisy to affirm that the majority of men in the prime of life could be induced to keep up total abstinence for such extended periods. Now, by teaching the women that intercourse

during the entire period of pregnancy and lactation is liable to make them invalids, we should naturally promote prostitution. And just this latter is the original cause of the invalid condition of so many women, while cohabitation during the larger portion of the above-named periods is not harmful. A proof of this assertion is found in the thousands of women giving birth to a child every year for a number of years in succession and enjoying the best of health.

Dr. Drennan asserts further that animals lead a more natural life in sexual respects than men. No doubt they do. But they live also in polygamy, which is more natural than monogamy, but which modern civilization has stamped as a crime.

One assertion of the doctor's is not founded on facts and is an insult to the human "males." Comparing them with the "animal males," she says: "In lower animal life this function is carried out according to law. Man is the only male who abuses himself and his female." This statement has no foundation in fact. Male animals, as is well known, follow no known law in satisfying their sexual appetite, but exercise it on almost every occasion. Moreover, monkeys frequently masturbate *cum manu*, as may be seen at almost any menagerie, while other animals produce an ejaculation by various methods of friction and by licking the genitalia, as has been often witnessed.

The article, in addition to all this, contains other fallacies, and in calling the attention of the readers to a few, I hope that they will analyze the entire essay and accept it at its true worth.

MAX TALMEY, M. D.

THE EVIL OF THE DOCTOR'S DRUG-STORE.

MANKATO, MINN., December 13, 1900.

To the Editor of the New York Medical Journal:

SIR: Oliver Wendell Holmes suggested that there might be an idiotic area in the human brain corresponding to the blind spot on the retina. Admitting such a condition, the medical profession must surely have been governed by impulses originating in this particular region when it created and fostered an institution so inimical to its own interests and the interests of humanity as the modern drug-store. The drug-store of today is, to a large extent, a combination of novelty or racket-store, an emporium for patent medicines, a shelter for counter-prescribing and substituting knaves, in all prohibition towns a saloon, and, last, a doctor's dispensary.

This dispensary in the ordinary country towns uses its prerogative to dispense with the labor of a pharmacist. Any smart, neat fellow will do just as well for less pay. The reason for this economy is that the doctor and the drug-store keeper are one, and he likes to cut down expenses. The doctor, or the man who works directly for him, gets in his quarterly supply of patent medicines and it goes before the public under the patronage or auspices of the doctor in charge.

"Smith's" or "Jones's" drug-store, which means to the people Dr. Smith or Dr. Jones, sings the praises of some nostrum in bad verse in the columns of the local newspaper or recounts the virtues of other nostrums. Patients come to the drug-store with a prescription from Dr. Somebody, and they see in the most conspicuous places, after they have picked their way through piles of holiday goods, rocking horses, and family Bibles,

those large rectangular packages warranted to cure all sorts of disease, with a promise to refund the money if it fails. The strong man is strangling serpents on somebody's nervine in a way that would make old Laocoon green with envy; the mild countenance of a prim elderly woman smiles on them reassuringly. A healthy-looking individual on Dr. Blank's new medical discovery beckons them. Another sure cough cure takes their eye, and so on.

By what occult science is an unfortunate patient to know that he has reached the land of liars? How is he to learn that what is here printed and bears all the evidence of earnestness and good faith, even the testimony of clergymen and statesmen, is simply catch-penny clap-trap to wheedle a dollar out of his pocket? Even the doctor whose prescription he carries, keeps these things for sale, so his heart goes out to these mysterious packages invented by a great doctor in some far-away city and put up by hands he has never seen. The dingy, dirty dispensary has no charms for him, and he naturally loses faith in the insignificant little bottle of medicine compounded by a boy he has seen "licked" in the last foot-ball game, and prescribed by a doctor whom he knows, for a fact, to be an ordinary mortal, subject to town taxes and water rates, when he can get for the small sum of one dollar a full pint bottle of the remedy of a great, mysterious, unknown doctor who hasn't to descend to the vulgar methods of finding out what ails him.

The doctor cannot well advise against the goods he carries in his own store, and the question here arises, What harm does it do? Some people are always tinkering at themselves and taking something for imaginary ills, and patent medicine, except for the alcohol it contains, is, as a rule, a very simple compound. But the fact remains that patent medicine comes between the doctor and the patient at the very stage of some of the most deadly diseases when the doctor's advice and care are a matter of vital importance. Patients are using nostrums during the early stages of cancer uteri, and only see a physician when there is too much involvement for safe action. Incipient Bright's disease, when professional instructions as to diet, habits, etc., are so urgently called for, is treated with other nostrums. That most deadly of all diseases, tuberculosis, seldom reaches the doctor's office until, under the benign influence of proprietary expectorants, the patient has reached that stage where labor is vain. Persons with anæmia are drenched with the whole line the drug-store carries before a physician's advice is sought. And so on to the end of the chapter.

The question now at issue is, What can be done to prevent this state of things? and we are told in answer that the people must be educated; but the people are being educated, and educated along wrong lines, by the doctors themselves. We should never forget that the most common, yet the proudest, appellation of a member of the medical profession is "doctor," which means "teacher." And we have taught with a vengeance. The result of our doctrinal ineulations since the days of Hippocrates to the present is a swarm of quacks and a supreme ignorance on the part of the people as to what is to be expected from a doctor. We are still looked on by part of our clients as devils, and by the other part as miracle-workers. But, not to wander too far from the drug-store, what can be done with it as a propaganda for fake slops? The law will not stop these productions, but the doctor can withhold his patronage by

standing aloof from the drug-store business and refusing to send his prescriptions to shops where they carry such a line of articles. Then patent medicine maker will be obliged to dispose of their wares at some other business stand. Let the people get their "safe cures" and their "sure cures" and their "discoveries" where they get their axle grease and kerosene oil, and the curative halo will soon depart from them. It may be argued that in a small town a dispensary cannot exist of itself but if the business is so small, the doctor can dispense directly—an old and very convenient custom, especially in these days when medicine is put up so neatly and in such small bulk. In conclusion, I would say that this is not written with any animus against the men who make their living by running a novelty-store with a dispensary in the far end of it, but with a strong desire to call the attention of medical men to the fact that honest medicine and patent medicine are incompatibles, and the sooner they are divorced the better for the good of humanity and the honor of the profession.

HELEN HUGHES, M. D.

Proceedings of Societies.

NEW YORK OBSTETRICAL SOCIETY.

Meeting of Tuesday, January 8, 1901.

The President, Dr. H. J. BOLDT, in the Chair.

Large Myomatous Growth of the Uterus.—Dr. JANVRIN presented a specimen. The history of the case was as follows: The patient was a single woman, forty years of age, whose menstruation was regular, without pain or bleeding. A month ago she had her normal period, which continued for several days, after which she began to flow freely. The hæmorrhage was controlled somewhat, but she continued to flow for several weeks. Upon examination at the end of three weeks, a large abdominal growth was found and the tumor removed. Several cysts of the ovaries were removed at the same time. The case was of interest because no hæmorrhage had occurred until the last month, although the mass was of large size. The reason for this was that the tumor was probably of the cystic variety.

Tubal Gestation.—The PRESIDENT presented a specimen in which the fetus, of two months, was found still within the tube. The great interest in this case lay in the fact that operation had been performed as the process of tubal abortion was taking place. The abdominal extremity of the tube was dilated to a diameter of a centimetre. The uterine end was completely occluded. The tube was two centimetres and a half in diameter at the thickest point. The patient had been bleeding for three months at irregular intervals and having cramp-like pains. During the week before the operation the bleeding was very profuse, so that her physician (who thought that the patient had an intra-uterine pregnancy) said that she would abort. Large clots were expelled *per vaginam*. The patient was very anæmic and suffered great pain. In the abdomen there was a large quantity of blood which had escaped at different times, as was shown by its varying degrees of consistence; some clots were recent, and bleeding was continuing from the tube, while some were very firm and yellowish-red, the latter being on the floor of the pelvis. The bleeding for such length of time without completion of the abortion was the main interesting feature.

Dr. VINEBERG said that the case was of great interest, showing as it did that there might be as profuse a hemorrhage from the uterus in ectopic gestation as from intra-uterine abortion. He also emphasized the advisability of giving an anæsthetic in cases of supposed abortion, in order to make a careful diagnosis of the actual conditions.

Dr. BROTHERS mentioned the fact that some men thought it unnecessary in cases of tubal abortion to perform laparotomy or to excise the tube. But in cases like that of Dr. Boldt's, in which the diagnosis of tubal abortion was made and the patient might lose her life from exsanguination, the loss of blood occurring externally or into the peritonæum, one was justified in making an abdominal section and removing the diseased tube.

Dr. JANVRIN remarked that in many cases in which surgeons were called to operate there was really a tubal abortion present and no rupture of the tube itself. It is rare for hæmorrhages to continue from a tube for two or three weeks without abortion being complete. In most cases tubal abortion took place within a week. In his opinion there was no question of the necessity of an operation in any case in which hæmorrhage was going on.

The PRESIDENT said he believed that a gravid tube could be treated like one of malignant disease, and an operation was therefore indicated.

Septicæmia and Pyæmia, and the Indications for Hysterectomy and for Abdominal Section and Drainage in Puerperal Infection.—The PRESIDENT read a paper on these subjects (see page 142).

Dr. VINEBERG said that he agreed with Dr. Boldt as to the indications for hysterectomy, but he personally preferred the abdominal route to the vaginal. He could not agree with the reader of the paper with regard to the definitions of sepsis. He thought there were no grounds for the introduction of the term "bacteriæmia." To his mind, there was but one kind of infection. Many times, from neglect, putrid intoxication ran into acute septicæmia, and the profession should be taught that in each case of sapræmia was one of septic infection from the onset, and that it might pass into acute septicæmia. Infection with other bacteria, such as the *Bacillus coli communis*, the staphylococci, and the *Bacillus aerogenes capsulatus*, had also been attended with fatal results.

Dr. STONE congratulated the reader of the paper on his successful effort to define the different varieties of puerperal infection. To his mind, the profession was too apt to think that there was only one form of sepsis, and that the correct thing to do in each case was to curette. This he thought a great mistake, as many patients got well without being curetted.

Dr. ABRAM BROTHERS thought that the question of treatment depended upon the recognition of the presence or absence of local infection. This infection might be due, not only to placental débris after delivery, but also to some condition of local infection occurring previous to delivery. He agreed with Dr. Boldt that, if the diagnosis of acute bacteriæmia could be made, hysterectomy or any other form of local treatment was contra-indicated. In his opinion, the terms "local sepsis," "acute bacteriæmia," and "chronic bacteriæmia" were well chosen.

Dr. W. E. PORTER said he believed that many cases would not come to hysterectomy if persistent intra-uterine irrigations were properly carried out. In his ex-

perience, the placental forceps was better than the curette for the removal of retained secundines.

Dr. MALCOLM MCLEAN had seen several cases in which lactation had given symptoms severe enough to make one strongly suspect septic infection, and he advised the greatest caution in making a diagnosis which would result in the performance of hysterectomy.

Dr. G. L. BRODHEAD referred to the cases of hysterectomy for retained placenta which Dr. Boldt had reported, and said that, in his opinion, if retained placenta could not be reached by the usual methods, it would be better to incise the cervix in order to get more space in which to operate. Certainly the greater part of the retained placenta could be removed in this way, and therefore hysterectomy would never be indicated.

Dr. JANVRIN said he had never removed a uterus for acute septicæmia, but he would ask Dr. Boldt to tell how one could know whether to perform abdominal or vaginal hysterectomy.

The PRESIDENT said that he would again refer to the excellent definition given by Coplin under the term "mycosis of the blood." We must recognize the fact that puerperal fever was always in a degree a septic infection. If fœtid discharges came from the vagina, it did not necessarily mean that the case was a serious one. Patients with acute bacteriæmia might have no fœtid discharge, and yet there might be an intense septic endometritis. We must watch our cases for a number of days or several weeks, and, if we found that all treatment had failed, the patient was steadily getting worse, no other cause for the chills, etc., could be found, the parametria were free, and there was no peritonitis, but perhaps streptococci were found in the uterine secretions, we were justified in considering vaginal hysterectomy. Abdominal hysterectomy should be considered only in cases in which we were called upon to perform a Cæsarean section on a septic uterus, or in which there was an intense septic intoxication associated with a septic endometritis, the patient's condition not improving under other treatment. The reason why the placenta could not be removed in the case reported by Schultze was that there was a uterus bicornis. In the other case, cited from Sippel, the general condition of the patient was such that it was not advisable to carry on intra-uterine manipulation further, so great was the danger of perforation. It required great judgment to decide in these cases what was correct to do, but each practitioner must judge from his own experience, with the aid of all the symptoms present. We should all endeavor to make precise definitions of the diseases that we were dealing with.

Miscellany.

Dental Surgery with the British Army at the Front in South Africa.—To those who regard the idea of military dental surgeons with some sort of scorn, a perusal of a very interesting paper by F. Newland-Pedley, F. R. C. S. Eng., L. D. S. (*Lancet*, January 5th), on Dental Surgery with the Field Force in South Africa, may be recommended. Mr. Pedley was dental surgeon to the Imperial Yeomanry Hospital at Deelfontein. For nearly six months he worked under varied conditions—on board ship, in a tent, afterward in a shanty, and subsequently in a hut. Occupation, he says, was never lacking from the first day of the outward voyage, for there was the usual epidemic of influenza, followed by numerous cases of neuralgia and

toothache. He had to attend to patients nearly every day, though only a few instruments were available, yet he managed to do some temporary fillings and some extractions, including a badly impacted wisdom tooth. At Deelfontein, 500 miles up country from Cape Town, he obtained "a shanty ten feet square with a tarpaulin roof." This "dear little place" became a dental surgery and also the editorial office of the *Devil's Fountain*, a camp journal established by him to while away the monotony. Mr. Pedley continues: "On March 25th a complicated fractured jaw case arrived, and as it was necessary for me to unpack my workroom appliances in order to construct a special splint, I was moved into a hospital shed, which I converted into a workroom and bedroom combined, and I had the use of the second, or reserve, operating theatre of the hospital for my consultations and operative work. The workroom was 27 feet long and 16 feet wide, and it was constructed of sections fastened together with bolts and nuts, so that it could be readily taken down and put up elsewhere if desired. Each section was 8 feet long, 5 feet 6 inches wide, and 4 inches thick, and it consisted of an outer layer of galvanized iron nailed on to a rough wooden frame and lined with deal boards. It was lit by four windows, each 3 feet 6 inches by 2 feet 6 inches. These huts, or sheds, were much cooler than tents in summer and were a much better protection against rain. For winter they were rather too well ventilated, as there was an open space of four inches all around the eaves, and there were about fifty large, square holes in the woodwork where the sections were bolted together. A fine breeze blew upward between the floor boards, and there was a wide chink around the floor which admitted a further supply of fresh air. The cost of a similar shed, better made and finished, would be about £50 in England, but these sheds were made in Cape Town, and were inferior in every respect to the English huts excepting in the matter of mobility. The draught under the boards could be reduced by piling earth around three sides of the foundation, and the industrious person who had the foresight to bring his own carpenter's tools could quickly exclude the frosty night air. With these slight improvements the shed made a very suitable workroom, and here I set up a casting bench, a plaster bench, and a jeweler's bench, with vulcanizer, lathe, and all necessary appliances. A smaller room would be sufficient for a workroom if additional space were afforded for storage and for a bedroom, but in a country where commandeering is recognized as a fine art and tools are in great request, the dental surgeon who elects to combine his sitting-room, bedroom, and storeroom with his workroom is wise. I covered the ugly walls with numerous prints and engravings, many of which I framed. This kind of workroom may be considered perfectly satisfactory for two or three mechanical assistants, in addition to which there is space for one bed 2 feet 6 inches wide.

"My operating and consulting room adjoined the operating theatre and x-ray room, and could be used at any moment as a second surgical theatre if it were necessary to perform two operations at the same time. The room was 19 by 16 feet, and was lit by seven windows. An attempt at top-lighting had been made, but it could not be said that the light was really good for dental manipulations. In this room I placed an operating chair, a dental engine, and all the instruments, appliances, and materials that I required for practice. There were, in reserve, a second engine and two more operating chairs for the use of possible assistants. I

worked strictly by appointment for all cases requiring fillings, and the ophthalmic surgeon was kind enough to give gas every day at 11:30 A. M. punctually. So much surprise may be felt that one should give gas to a soldier for the extraction of a tooth—and it would not be necessary if the patients were not sick, but hundreds of them were recovering from typhoid fever and dysentery, which left them in a very weak state. A man with nine bullet wounds, who was known amongst his friends as 'the man who stopped a whole volley,' was a very brave fellow, but he was glad to take gas for a severe extraction.

"The work required of me at Deelfontein was little more than the work of a dental practitioner, and I had a very few severe gunshot cases, which I treated in conjunction with Mr. Alfred Fripp. Gold fillings are rarely necessary in a military camp, but the percentage of exposed pulps is very high, as nearly every patient would rank as a neglected case. Disease, neglect, tobacco, beef, and hard biscuit play havoc with the teeth—a young man had only three useful teeth left. How such patients recover from typhoid fever and dysentery is a mystery. They are of no further use as fighting material under the present régime, for they cannot eat solid food. Nothing is done to preserve the soldier's teeth while he has any, and when they are gone he must go home as a man unfit for service. It would be better and quicker to put a soldier's teeth in order than to train a fresh man as a substitute for the invalid. The officers suffer with their teeth after a few months' campaigning, and I hear on the best authority that there were at one time at Modder river eighty officers requiring dental attention, and they sent to Cape Town for a dental surgeon. Unfortunately, they were again on the march when he arrived."

As regards the establishment of a dental service in war time, Mr. Pedley says: "At first sight it might seem desirable to attach a dental surgeon to each regiment, brigade, or division. Experience in South Africa, however, has left no doubt in my own mind that it would be better to make such appointments to the general hospitals, and perhaps to the stationary hospitals also, where the transport rations and sleeping accommodation for two or three such dental officers could easily be added to that already required for the staff of twenty-five medical officers. Each of the numerous general or base hospitals in South Africa should have been provided before it left England with a dental unit consisting of a dental surgeon and two senior dental students as assistants. In Deelfontein it would have been impossible for me adequately to tackle the dental work of our thousand-bedded hospital without at least two assistants. What must the condition have been in the general hospitals at Cape Town, Kimberley, Naauwport, and Bloemfontein? My chief experience was drawn from our camp of 1,000 souls, but in the latter place alone there were 5,000 sick in hospital, to say nothing of the 30,000 troops left encamped there after Lord Roberts moved north with the bulk of his army. At each general hospital there should be an operating room with three chairs and a workroom for the construction of special appliances and dentures. Each stationary hospital of 200 beds should similarly have a dental surgeon upon its staff, but workroom appliances are cumbersome and heavy as compared with surgical instruments, and patients requiring dentures should be sent to the general hospitals. The dental units should be supervised by a chief dental officer at the base in the same way that the principal medical officer supervises all medical units."

"To meet emergencies and the requirements at the actual front—as, for example, after a great battle or during a protracted halt of the army—the principal dental officer should have a small reserve of dental officers who could be drafted to any point on the receipt of the necessary intelligence from headquarters. The equipment of the dental officers who were sent to the front would, of course, be as light as possible. The dental engine packs into a small space and all the necessary instruments and materials would go into a case one cubic foot in measurement. Dental officers at the front could obtain additional supplies, if necessary, from the nearest general hospital. No special operating chair could be taken to the front; all that is necessary is a portable headrest that can be fixed on to any chair. In large hospitals portable operating chairs weighing eighty pounds each and costing seven guineas would be useful, and a strong operating chair for anæsthetic operations would be desirable in addition."

Financial Responsibility for Care of a Wounded Prisoner.—A man named Butter was arrested in Cleveland on May 19th for assault and battery, and, attempting to escape, was shot by a policeman. He was taken to the general hospital for treatment under guard, and a few days later was arrested. He remained in the hospital under treatment until October 13th, when he was transferred to prison and later tried and convicted. The hospital authorities presented a bill for his treatment, amounting to \$148, to the police department, which declined to pay it. The county solicitor says that the county should not pay the bill as the prisoner was not in the jurisdiction of the county court until he was arraigned in the police court on October 31st. The case is one involving several interesting legal points.

New Medical Practice Act for California.—A bill to regulate the practice of medicine and the certification of physicians in the State of California was introduced in the senate at Sacramento recently. The bill embodies the suggestions made by the committee on legislation of the State Medical Society. It provides for a board of medical examiners, five to be elected by the State Medical Society, two to be elected by the California State Homœopathic Medical Society, and two by the Eclectic Medical Society. They are to be elected annually, to serve one year. Provision is made for accepting certificates from other States. The application fee is placed at \$20. Certificates may be revoked for unprofessional conduct, after proper hearing. Unprofessional conduct is defined to include criminal practice, obtaining a fee for the assurance that a manifestly incurable disease can be permanently cured, wilfully betraying a professional secret, advertising one's business or medicines, conviction of any offense involving moral turpitude, and habitual intemperance.

The South African Hospitals Commission, which has recently published in London a report of its work and conclusions, is said to have recommended the appointment of a committee of experts to define the steps necessary to secure qualified officers of the medical corps to undertake sanitary duties, to prevent orderlies pilfering stimulants and the comforts of patients, and to relax strict military rules so as to give patients an additional feeling of ease. According to a press dispatch, the commission says: "The evils are serious and ought not to be minimized, but, reviewing the campaign as a whole, it

cannot be said that the medical and hospital arrangements have broken down. There has been nothing in the nature of a scandal in the care of the sick or wounded, nor any widespread neglect of patients, nor any indifference to suffering. In no other campaign have the sick and wounded been so well taken care of."

Higher Standards for Medical Education.—The University of Pennsylvania, at the beginning of the present school year, adopted a curriculum embodying four years of exclusively medical study. This new curriculum has just been adopted by the State Medical Council, at its winter meeting, as the standard for Pennsylvania. Under this newly adopted standard the applicant for admission to a medical college must have attained a high degree of general education, and he will not be admitted to advanced standing in the medical school on the ground that he has, for instance, studied anatomy in an art school, or chemistry in an electrical school. The fact that ninety or more applicants out of about 250 were rejected last September in the university examinations is taken as an indication that the new curriculum is to be lived up to, in spite of its immediate financial drawbacks. About ninety per cent. of these unsuccessful applicants have been admitted to other schools, a fact which is regarded as a thing that cannot occur again under the State's new standard. The attorneys-general of all the States in the Union have been made interested in a movement to make the standard of medical training in Pennsylvania, or its equivalent, the standard of other States. After lengthy correspondence between the Pennsylvania Medical Council and the medical boards of other States, a bill in Congress is now proposed extending the elevation of the medical standard throughout the United States.

Disease in the Philippines.—In the report of the Taft commission to the President concerning the Philippines, the following remarks are made regarding the climate and diseases of the Philippines: "It is believed by this commission that no tropical islands in the world enjoy a better climate than do the Philippines. While this is true, two classes of diseases have to be reckoned with here. These are, first, diseases common to temperate and tropical countries, and, secondly, diseases especially characteristic of the latter regions. Under the former head would fall small-pox, cholera, bubonic plague, and leprosy. Small-pox is endemic in these islands. The natives have very little fear of it, and are apt to neglect the necessary precautions to prevent its spread, unless compelled to adopt them. Experience has shown, however, that it can be stamped out by thorough vaccination. A particularly effective virus is obtained from the water buffalo, in a laboratory established at Manila for this purpose by Dr. Frank S. Bourns. Similar laboratories will be established at convenient points throughout the archipelago, and a vigorous attempt made to vaccinate the whole population.

"There have been more or less destructive epidemics of Asiatic cholera in the Philippines in the past, but they have occurred at long intervals. The last was in 1888-89. Cholera has not appeared in the islands since that time, but we are near China, which is a breeding ground for disease, and danger from epidemics imported from that country can be avoided only by the maintenance of a strict quarantine service."

Bubonic plague appeared in Manila in December, 1899, but has never made any considerable headway. No systematic effort has ever been made to stamp out leprosy

in these islands. The report recommends the isolation of the lepers in a small island. It is confidently anticipated that the establishment of a department of well-organized public health will lead to a general improvement in sanitary conditions. Under this subject the report also treats of the climatic effect upon sick and wounded soldiers.

Havana's Death Rate.—A carefully compiled and elaborate report of the vital statistics of Havana for the year 1900 has been issued by Major W. C. Gorgas, chief sanitary officer of that city. From these official figures it appears that there were 310 deaths from yellow fever in Havana last year, as against 103 in 1899, and 136 in 1898, a substantial increase. This growth of the death list, which exceeds that reported in 1890 under Spanish rule by two, may partly be attributed to the large immigration, no less than 24,124 foreigners settling in or passing through Havana in 1900. The real triumph of American methods of governing Havana over the Spanish system is shown by a comparative table of deaths from all diseases from 1890 to 1900. In 1900 the death rate per thousand, despite the increase in yellow fever, had sunk to 24.40 from 33.67 in 1899, and 91.03 in 1898, the latter being the highest figures of the decade. Even in normal years of the Spanish rule, such as 1893, the death rate was as high as 32.01. It must not be overlooked that the population of the city has risen steadily during this period, numbering 250,000 in 1900, or 31,500 more than in 1893.

A Pen Portrait of a Great Surgeon.—As tending to show a rare combination of geniality, exuberant good humor, modesty, forcefulness, and energy, with the more strictly scientific attainments that go to make up the ideal disciple of *Æsculapius*, we abstract from the *Medical Dial* for January the following pen portrait from an article on *The Surgeon in War*, by Charles E. Hands. The author was in bed in Mafeking with a bullet in his thigh. He says:

"After Dr. Davics had gone away with his regiment on General Mahon's march, I was lying in bed one day minding my bullet, and thinking about the time when I should get up and go for a walk, pondering the terrible abyss of time that stretched between breakfast and lunch, and wondering about all the kinds of things that people wonder about when they are minding bullets, when I heard a strong, hearty man's voice in the house, and there came into my room the most cheerful-looking old gentleman I have ever seen in my life. A hearty, healthy, vigorous old gentleman, who came bustling in full of life and energy, with a whimsical smile on his shrewdly good-natured, kind, beaming, big, broad, clean-shaven face.

"'Weel,' he said cheerily, with a Scotch accent, as he took my hand between his two big, firm palms and gently shook it, smiling meanwhile like a benevolent uncle, 'weel, I've just come to see how ye're getting on. Eh, but I know all about ye! Eh, my laddie, but they're all verra cansairned about ye down country there. And I'm glad to see ye.'

"And he continued to shake my hand and smile, and I smiled back and shook his hand, and said that I was—as was perfectly true—downright glad to see him, although I hadn't the faintest idea who he was, except that I seemed to know at once that he was a great surgeon.

"'Then,' said he, 'I'll just give ye my caird'; and if he had said he would just give me a thousand pounds he

could not have said it in a kindlier tone of impulsiveness and benevolence. I remember saying, 'Thank you, sir,' as he took the pasteboard he handed me. It said in plain formal type, 'Professor John Chiene, consulting surgeon to the forces, South Africa.'

"Professor Chiene! I had never seen him before but I had known of him all my life. One of the famous surgeons of the world. Dozens of times I had heard of doctors who had been Edinburgh students exchanging pleasant reminiscences of John Chiene. This was a slice of luck indeed.

"I said what I had to say, and he went on to tell me that 'Airchie Hunter'—that was General Hunter—had given him leave to come up to Mafeking to see if he could be of any service to the wounded lying there. I seemed to think that it was a personal kindness on the part of Airchie Hunter to let him come, and I am sure that he felt positively grateful to the wounded for giving him the opportunity of coming.

"But at that time I knew that General Hunter's division was a hundred odd miles away, somewhere on the other side of Vryburg, that there was no railway through, that there were only rough, boulder-strewn tracks for roads, and that the only people on the way were low-class Dutch, who were nearly all rebels and thieves. How, then, had he managed to get through Mafeking, I asked him. Did he have an escort? Oh, no escort—capital adventure to come without an escort.

"He had made the journey in a sort of rough cart—the most enjoyable kind of traveling in a rough, jolting cart! One of the horses had broken down—splendid fun! Had slept out on the veldt—glorious sleeping on the veldt! Never was such a blanket! They got water one day—extraordinary fun being thirsty! He had given a lift to a belated correspondent on the way—capital chap, that correspondent! Most entertaining companion! Had just got to Mafeking and found a lodging in the remains of what had been a hotel before the big shells knocked the end wall out and the roof off—charming place, Mafeking! Beautiful sight, all the bare sand! Capital taste sand had, too, in your foot! And how lucky to find a room in the hotel with the end wall out and the roof off. Most convenient for looking out of! And the ration bread made out of bran! Really most wholesome food and wonderfully agreeable eating!

"Buoyant!—why, Professor Chiene would have floated in hydrogen gas. He told me a story about a Scotchman enjoying himself at a funeral, and laughing as he told it, and made me laugh till I could feel my bullet wobbling about in its hiding place. He made me feel so much better that I wanted to get out of bed and practise walking, but he wouldn't let me.

"Then, when my doctor came in, he got to business. He ceased laughing and put on a grave, thoughtful, shrewd look, though he still kept a keen, humorous twinkle in his eye, and went into the consultation. He listened alertly to the doctor's description of symptoms, and to my own, and then he put in some unexpected and seemingly inconsequent questions, which reminded me of something I had forgotten or failed previously to observe. Then he felt over the surface of my leg with his finger-tips so sensitive that they almost seemed to feel what was underneath, and in a few minutes he knew all about my bullet and my thigh bone, and just what was to be done and when and why. And everything he said turned out to be true, and everything he recommended to be right."

Original Communications.

STATE CARE OF THE INSANE.*

By HENRY WALDO COE, M. D.,

PORTLAND, OREGON,

MEDICAL DIRECTOR, MOUNT TABOR NERVOUS SANITARIUM; CONSULTING ALIENIST, OREGON STATE INSANE ASYLUM; NEUROLOGIST, MULTNOMAH COUNTY HOSPITAL, ETC.

If there is any man that needs a doctor, that man is an insane man. If there is any man who should be provided with a physician, that man is an insane one. He is the sickest of individuals and is unable himself to plan for his own wants. Others must not only care for him, but also plan for him. It is with a view of discussing methods for his care that the present paper is presented to the general profession, for from such discussion must come the influences needed to effect the reforms which are to correct the evils of the methods in vogue to-day. The men who must bring the truth home to the profession are those who have to do with the care of the insane.

While these methods will largely put out of existence the private retreats, dependent upon the insane for patronage and maintenance, yet I feel that those connected with such private institutions on account of the independence of their positions, must take a leading part in this modern crusade against methods which have largely outlived their days of usefulness. In this regard those who are administering private institutional care to the insane as a portion of their neurological work, are doing no more than every one of you does each day of his life, when you cut off your own incomes, by the advocacy of purer and better drainage against typhoid and diphtheria, and of quarantine to suppress scarlatina and small-pox; moves which the public little understand or appreciate, although the medical profession is full of this work in which a consciousness of duty performed is the only reward received.

It is almost a matter of supererogation, in passing, to compliment the medical men who have to do with the insane in public asylums. Although these men are largely chosen on account of political influence, the *personnel* has generally been excellent. Alienists have not always been selected, but the governing boards have sufficiently felt their responsibility to exercise much care in this matter, so that the medical officers have usually come from the better class of our doctors. In your own State you have been specially fortunate in this regard, and your asylum at Blackfoot is a model of the best American methods existing to-day.

The medical men in State institutions, if they have not become callous to their surroundings, feel the needs of their unfortunate charges, but they are largely helpless to effect the greater changes that they desire. They are, however, working toward the goal to attain which

alienists everywhere are striving, and it is our duty to lend a willing hand to all such efforts.

The care of the insane is one of the greatest financial burdens of the State. To produce an appearance of economy in this matter is the first demand of the governing board of every public insane asylum in America. The cost *per capita* for maintenance, in the eyes of the powers that be, is the important portion of the medical superintendent's report. It is not the question of reduction in the number of patients that is most interesting, but the financial one of the individual cost for each. The superintendent who discharged fifty per cent. of his inmates as cured during a given year and reported also that the *per capita* expense had increased twenty-five per cent., as it would necessarily have to do, would, under the usual system, be looked upon with suspicion. The medical side of the patient's condition is markedly secondary to the financial. Thus it is that a goodly number of our public institutions retain many inmates, harmless bodies, who are reasonably contented with the institution, and are able to do much work and give little trouble, because this class helps to make up the averages that are to satisfy those in authority in such institutions.

You can scarcely to-day take up a single report of a public insane asylum in the land, which is not crying out for more room. Crowded wards with patients in the corridors is a common statement in such reports, and the system of herding the insane in certain quarters grows day by day more pronounced.

At the Utah State Medical Society at Salt Lake, this week, several medical men were pronounced in their advice that children afflicted with chorea should be isolated in order that suggestive influences should not affect other pupils in the same school. If this is a desirable end in such regard—and who can doubt it?—what of the effect of crowding patients together in an asylum—susceptible persons in the condition found in the insane?

Especially harmful is the usual asylum influence upon cases when in a state of convalescence. Patients who are fully recovered are supposed to be returned to their homes, and only those retained who are still ill, so that, no matter how careful the management may be, even the convalescent wards are largely filled with those who are still mental invalids, subject to the various vagaries of their several forms of insanity, the study of which has now the closest attention from their fellow inmates whose reason is reasserting itself. Besides this, most insane patients possess, after recovery, a hazy memory of all that has transpired about them, and in some instances such memory is extremely acute.

Much of the public feeling regarding the insane is dependent upon the view that the law takes of these individuals, and especially as to their examinations for lunacy and commitment to the asylum.

Let us take an everyday experience. A man of good

*Read before the Idaho State Medical Society, Boise, October 5, 1900.

family connections and possessing ordinary breeding and refinement suddenly becomes insane. He is, perhaps, somewhat demonstrative; possibly he is a melancholic and he may have attempted suicide. His family physician, his friends, and the sheriff are called in for advice. For purposes deemed best for the safety of himself and his family, he is taken to jail. He is thus treated as a pickpocket, a horse thief, or a murderer would be, and is brought into association with such other criminals as may at this time be under confinement. The next day a court convenes, and among the prisoners at the bar appears our mental sufferer. An examination is held, which, although the patient's best interests are honestly sought, smacks throughout more of star chamber proceedings than of those having reference to a righteous regard for the personal liberties of a fellow citizen. Very often the grossest deception is practised upon this man, who is under trial involving both his liberty and his peace of mind for all his future days, and often, although he may be able to comprehend everything reasonable presented to him, he may find himself in the insane asylum, placed there under one subterfuge or another, before he can realize what is being done with him. Possibly his delusions are fattened by the measures taken to get him peaceably to the asylum, and sometimes such delusions are thus so thoroughly crystallized that weeks of treatment are required to overcome the evil effects of a few hours' detention in the hands of the officers of the law. Reference has been made to a man, but the same deplorable state of affairs often occurs in the case of a sensitive woman.

This picture is a true one in nearly every week in the year in most of the States in the Union. The State is responsible for the initiation of the method, but we are to blame for its continuance. The individual before us, to whose care we may have been professionally called, is not a criminal, but an invalid, and this method of treatment to which we have been a party is not right from any standpoint. It may be argued that there is no other place than the jail to take the patient to, and that the care required is not otherwise attainable, but this is not usually the truth. In almost every case better things could be brought forth for our patient than he has received.

I remember, many years ago, while in general practice, the case of a young man who was injured in a railroad wreck. He had received a compound fracture of the leg and other traumatism, including a blow across the head. He was actively delirious for two weeks, and I am sure that I have never seen an insane case more difficult to manage than he was. Because his was a surgical case and he was not technically insane he received the benefit of private care in a general practice. If as good judgment were employed in mental cases as in the lines of other practice, insane patients would be started off upon their mental journey in a much less striking and depressing manner than *via* the jail route.

It is much more economical to care for a certain number of patients in large bodies than individually, and on this account present asylum methods came into vogue. The medical officers are making every effort possible for improvements which *must* be made, so that they are often unable to demand things which *should* be made. It costs less to feed and warm a certain number of patients, and especially to furnish attendants for them, when the insane are maintained in wards of considerable size, than when living in cottages containing from two to half a dozen patients each. The benefits to the patients in the latter method are, however, quite manifest. I have seen a number of asylums where in a single ward from forty to sixty patients were confined, over whom were placed two or three attendants in the daytime and a less number at night. How much time has an attendant to put in upon a single patient under this state of affairs? Very often under private care, or in private institutions with ample accommodations, three hours a day is required in feeding a single patient. In the absence of ample help the stomach tube must be brought into service and, when necessary, passed from patient to patient. The tube is necessary in some cases, but with a patient under a tactful nurse this may generally be dispensed with. This method of feeding is one of the things which a patient remembers long after recovery, and it is very desirable that no such event shall have been a portion of his mental illness.

The fault with asylum nurses is not one relative to the individual, but that of a system necessitating work from one person, and that hurriedly done, which should be accomplished by a half dozen or more. It begets a routine method of daily care which in a few years unfits the asylum nurse for the care of outside cases, and it is against my rule to employ these individuals for my own cases. Worn out by the grosser cares of numbers, they have acquired a type of character that does not easily permit their transformation into that type of an individual who must be burdened with the intricacies of the individual.

In the curative forms of insanity, and this paper necessarily refers to them, the rays of mental light must be closely watched for and their sources cultivated, for it is by the growth of such normal awakenings that full mental health is to return. The invalid needs close observation and individual care to this end, that every tendency toward health may be encouraged and convalescence be accelerated.

I was struck by the number of attendants in the Morningside Asylum at Edinburgh, not less than a nurse or companion for every two patients. I inquired of Dr. Clouston how he was able to procure the necessary funds for such work, telling him that in America the canny Scot was looked upon by others as extremely calculating in regard to his financial expenditures, yet the appointments at Morningside seemed to have been effected regardless of expense. "Yes," said Dr. Clouston. "and

that is the very reason why I am able to secure more attendants in Scotland than I should be able to do anywhere else in the world. The Scot is a good business man, and he is willing to spend a few thousand pounds to-day if he can save more money thereby to-morrow and the next day. As an example, look at this patient before us. The average life of the individual of his type in an insane asylum, under ordinary methods of care employed elsewhere, is twenty years. In other words, these cases usually die in such institutions. You will note that I have with him a very intelligent gentleman, a retired tradesman whom business reverses brought into my employ. This nurse is very much above the ordinary in intelligence and tactfulness. He has no other patient to care for. It is his entire duty to attempt to bring this man up from his mental depression and out of himself into a normal atmosphere. Six months of this care will doubtless permit me to dismiss this patient. This is an example of the benefits of our methods, and shows how we are able to save money while we are freely expending it."

The medical officer of every insane asylum in the island feels the need of more nurses and attendants, but, in the race for a *per capita* exhibit, his board will not permit him due latitude. Again, the political aspect of public asylum records, in which one political party seeks to make a showing, from a financial standing, more favorable than its political foes have done, even where the medical officers are not subject to change for political reasons, is one of the most pernicious features of the expense side of this important subject. There is that ever-present demand for more room, which must somehow be met in our rapidly growing country; and bolts and bars, relics of a passing era, must be made to take the place of needed attendants. Bolts and bars have only an initial expense; attendants, nurses, and companions entail financial burdens which never cease, and so the massing of patients goes on, to the detriment of all concerned.

Then there is the medical side to the case. In your own State asylum you have Dr. Given, the noblest Roman of them all. He has general supervision of his institution, and that should largely be the sum of all his work. He should select the physicians who are to act under him and for whom he should be responsible, but the State ought not to expect him to be liable for the individual medical care of his charges. His time and responsibility should extend to the selection of proper medical and other assistants. He should see that his patients are properly fed, clothed, warmed, and employed, and he should have time to work out the newer problems for the enlargement of his institution and the individual benefit of its inmates. He should travel much in this country and abroad, at the expense of the institution, for the benefit of these charges of the State. A single individual has but a limited amount of energy and strength, and it is unreasonable and unjust to ex-

pect from any single man the work expected of him. He is not able to do the work of half a dozen persons, and there is no need of attempting to lull your consciences into the belief that the State is doing its whole duty because it even has at the head of the asylum a man of the experience, ability, breadth of character, and tenderness of heart possessed by Dr. Given. For every fifty patients in the institution a skilled alienist should be employed, and he should assign such physicians to the various groups of patients as from special fitness for the position, and other reasons, seems best to him. These physicians should be held strictly accountable for their patients, and as thorough individual care should be exercised in each of them as though the patients were suffering from any other serious illness. The medical care of several hundred patients, when it devolves upon any one man, as it does in many insane asylums in this country, is, from a rational and scientific standpoint, something of which we have no reason to feel proud.

Your own State could furnish these medical assistants. They ought to be physicians possessing some natural adaptability and an interest in the subject of the care of the insane, who could, when assured of a position during competency and good behavior, take the time for the necessary preparation for such work.

The cottage plan of treatment would naturally follow such a division of medical work. While one or two individuals could scarcely walk the multitudes of miles necessary to see the number of patients in an ordinary asylum where the cottage plan was in operation, with the work thus divided sufficient time could be devoted by the physician to every patient in the institution. The number of attendants would necessarily have to be increased. Those strictly employed in the nursing care of the cases should not be less in number than an attendant for one or two patients, and this care should be divided between nurses, attendants, and companions.

These desultory thoughts in criticism of present public sentiment regarding the care of the insane are presented largely in the interest of the poorer classes. There are numbers of private institutions over the country where the sick may be able to recover, away from ordinary asylum life, if the patient or friends possess the financial ability to maintain such treatment; but these facilities are denied those financially less fortunate. These poorer classes, too, furnish the larger proportion of those born with a mental defect and subjected to the more trying ordeals of life, and they should therefore be the most tenderly cared for, that there might neither be unpleasant recollection, nor imperfect recovery, to invite a recurrence when the harassing cares of life have again been taken up.

Physicians in general practice do not always understand and fully realize the import to the patient of detention in an insane asylum, or I am sure that many cases that are sent there at the present day would be cared for by the family physician or otherwise treated

away from public institutions. The public asylum is an extremely useful institution, even in its present form, and we could not get along well without it, but it should not be invoked except in cases of actual necessity, and the responsibility of the family physician in this regard is one of the greatest that falls to his lot in the practice of medicine.

It is not easy to drive from my memory the bitterness of mind displayed by a certain convalescent patient who has been returned recently to her home. She was a woman of a family in good circumstances, who was taken with a mental illness many months previously and, during the consequent distress of her family, hurriedly sent to a State insane asylum. She was supposed to be a hopeless case. After some months' detention, her family in the meantime having canvassed the subject of the treatment of the insane, she was transferred to a private institution, where, in due time, the recovery referred to occurred. Her bitterness over the public commitment was intense. Time and again she referred to the fact that for weeks she had cared for her husband, who was very ill and delirious with a sickness from which he had recovered; at the close of which, on account of the sleepless nights, care, and anxiety connected therewith, she herself had broken down, and had then been made subject to the odium of asylum life, the recollections of which were to her extremely unpleasant, when private care was quite within the reach of her family. She could not see why she should be made a State charge, believing, as she had a right to do, that she was no more sick than her husband had been, to whom every detail of care was furnished which money could afford.

Another case was that of a prominent gentleman, whose brother had years before died in a public asylum after ten days' sickness, and who was himself taken with a similar form of mental illness. On their way to the asylum his friends stopped with him in Portland and there first learned that there was a retreat in which he might be cared for. He soon began to improve, and within two weeks was in a normal mental state and was transferred for convalescence to one of the cottages of the sanitarium proper. He had a large family of grown-up sons and daughters at home, several of whom I have met, and I have scarcely before witnessed such bitterness against the family physician as in this instance. The doctor was a warm personal friend of mine, and had himself formerly recovered from serious neuralgia after a few weeks' treatment in the sanitarium, and I am sure of his friendliness toward our institution. He had, however, made a positive diagnosis and a positive prognosis regarding this case. He said that the patient would surely die, and that quickly, too, and that he should at once be taken to an asylum. My medical friend made, as we all occasionally do, a grave mistake, and he deserves censure in the present instance, although not to the extent to which the family threatened

him, and which, I believe, I was the principal agent in overcoming. The burden of the criticism was largely based upon the fact that the doctor was not a specialist upon insanity, and that he should have declined to entertain so positive an opinion upon so important a subject; that, on the other hand, he should have referred the case to a specialist for such opinion; and further, they argued, in any event, since he knew of a private institution, if the patient was to die in the short time indicated, the family had the right to have such death occur outside an insane asylum.

It will take more than the change of the name "asylum" to that of "hospital" to remove from the memory of the inmates of such an institution the gruesome recollection of the restraint and association therein necessarily a part of present methods, although to the friends outside the change may appear as a euphonious improvement. The word "asylum" is a good one; it means a resting place, a house of peace. We need not seek to change this name, but rather seek to make this institution what its name truly indicates, and in this matter we all have, as a duty, the obligation of assisting those in such institutions who are seeking to effect the reform here indicated.

When the day of such consummation arrives, as it surely will, when the word "asylum" shall have a pleasant sound, private retreats will have largely passed away, and we may feel that we have done our part in giving to an honorable name a meaning which will bring back happy memories to all those who have received mental strength under the pleasant environment of the institution which the term will describe.

THE NORMAL DECLINATIONS OF THE RETINAL MERIDIANS.

By GEORGE T. STEVENS, M. D., Ph. D.,

NEW YORK.

(Concluded from page 278.)

DECLINATIONS AND THE CONTOUR OF THE BROWS.—

This leads to a part of the subject which, while in the line of the discussion, passes from the domain of painful affections to that of facial expressions. The scope of this article does not permit of more than a mention of a few of the peculiarities in the contour and the symmetry or asymmetry of the two brows. The subject when considered in all its bearings is most interesting, but it will serve the present purpose to mention three of the most conspicuous forms of expression about the brows which are in direct relation to the declinations of the meridians. So characteristic are these that when either is conspicuously present it is easy, not only to recognize the class of declinations, but to tell the direction of the leaning of each eye.

In the form in which both brows slant or arch upward from the temples toward the median line, the internal extremity ending almost in the general direction of the line of slant or suddenly curving down at the inner end as it is seen in the diagram (Fig. 5), we may look for

FIG. 5.

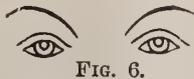

FIG. 6.

positive declinations for both eyes and of nearly the same extent. It is an expression which, some years ago, I associated with exophoria, but the more recent observations show that not only the expression but the exophoria itself has its cause in the direction of the meridians.

A second form of direction of the brows which is also most frequently associated with exophoria, but which is sometimes found with esophoria, is that in which each of the brows ascends from the inner extremity outward, forming what I have called "the bird's wings" eyebrows (Fig. 6). Here the declination is positive for each eye, but the extent of the declination differs materially in the two eyes. Such a declination may, when the positive declination is quite moderate in one eye and is more de-

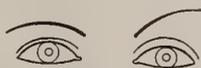

FIG. 7.

clined in the other, give rise to esophoria, but the nearer the approach to equality of declination in the two eyes the greater the probability of exophoria resulting.

Again, the position of the brows assumes the directions shown in the diagram (Fig. 7). The diagram here appears somewhat extravagant, but it is a common form of expression, and a close observer will soon find that it is

by no means exaggerated. It is a form of expression which indicates homonymous declination with the positive leaning at the side with the compressed brow and the negative leaning at the side on which the brow rises toward the temple. One of the common modifications of this form is that in which both brows curve strongly, but one is drawn much farther upward than the other.

It is easy to see that a great variety of modifications of these three forms of expression about this part of the face may arise from variations in the kinds and proportions of declinations in the two eyes.

AMBYOPIA AND DECLINATIONS.—The plan of this article will not admit of entering upon details of the irritations and disturbances of vision resulting from phenomena within the eyeball which still have their origin in unfavorable inclinations of the meridians, but it will be seen that such a cause might well give rise to many disturbances, not only of function, but of nutrition. There is one form of visual affection, however, so distinctly connected with and dependent on declination that it must not be passed by without some special notice. It is the amblyopia which is not infrequently found in apparently well eyes and in which there is no squint. It is not difficult to understand that the ever-recurring confusion arising from the partial diplopia from failure to maintain a correspondence in the position of the meridians of the two eyes would induce such amblyopia. This emphasis upon the simple uncomplicated amblyopia does not imply that declination has no part in the amblyopia of strabismus or of astigmatism. Without doubt it is an essential element of both.

Asthenopia, very naturally, is one of the common and characteristic symptoms of declination.

MORE GENERAL SYMPTOMS.—Without pointing out other local symptoms, a cursory glance at more general disturbances having their origin in declinations will be necessary. These general symptoms may, like the local ones, be the direct or the indirect result of the ocular anomaly. For example, certain symptoms which are characteristic of the general nervous state known as neurasthenia are among the direct effects of declination.

The habitual pose of the head and, indeed, that of the body are in a large measure influenced, it might be said controlled, by peculiarities in the normal adjustments of the eyes. Independent of the position of the normal plane of vision, which has an important controlling influence upon the pose of the head and body, when there exists a positive (+) declination for each eye the head is, in many cases, thrown backward as it is when the plane of vision is low. This high carriage of the head is commonly associated with chronic pains at the base of the skull, at a point over the spine of the seventh cervical vertebra and at points between the shoulder-blades or just below each scapular angle, with habitual aching in the lumbar region. If, in these cases, the plane of vision is raised where it was originally low, or if the positive declination, when it exists, is corrected, the head is no

longer habitually thrown backward, the back no longer bends in, the tension is removed from the muscles, and relief from the pain is experienced.

Vertigo is one of the symptoms so closely related to declinations that it may be said that, in general, vertigo is the direct, not the reflex, effect of the declinations. Carried to its extreme manifestation, the vertiginous attack becomes epileptoid, and without doubt the underlying principle in both vertigo and true epilepsy is the same.

The more recent experiences with ocular causes of epilepsy, and beyond a doubt a great proportion of idiopathic cases of epilepsy have for their cause ocular conditions, show that when we arrive at the root of the matter the declinations are the most important if not the essential of these ocular elements. The relief which often follows correction of the refractive errors or the anomalies of heterophoria may probably be due largely to the fact that with the greater freedom of action of the adjustments of the eyes and the consequent relief from fatigue the management of the declinations becomes less difficult and disturbing. If we proceed directly to correct the anomalous declinations, the results upon the epileptic state are much more certain and more quickly and permanently marked than when the heterophoric conditions are alone treated. Whatever the theory may be, the fact is that in many cases in which the correction of refractive and heterophoric anomalies only modifies the epileptic state a correction of declinations serves to arrest the epileptic seizures.

Space does not allow of any extended mention of insomnia, dyspepsia, mental disturbances, and many other forms of nervous reactions which in very frequent instances have their origin in the class of defects under consideration. Enough has been said to indicate that declinations are important elements of nervous irregularities, and if that is established it follows that the forms of manifestation may be numerous and varied.

TREATMENT OF DECLINATIONS.—While, under certain circumstances, glasses, spherical, cylindrical, or prismatic, may and doubtless do have an influence in inducing or in correcting declinations of the images of objects, no practical and systematic use of lenses can be made in the treatment of this class of anomalies. It is only important in this connection to remark that declination of the images (not of the eyes) is easily induced by a bad adjustment of strong lenses, and that the greater care which is observed in the adjustment of glasses in recent over not very remote times is even more important than it is generally supposed.

Practically, correction of the declinations can only be done by surgical interference. Without discussing the advantages or the disadvantages of such interference, I shall proceed at once to suggest some of the surgical measures which have thus far proved more or less effective in my hands. Of course there can be no direct method of reaching the declinations, a modification of the tension of the obliques being the nearest approach to this,

and it would be a bold and probably a most imprudent surgeon who should undertake to change the action of these muscles. There is left, then, only such indirect influence upon the position of the eyeball as can be brought about by changing the direction of the action of the recti muscles.

If with declinations there coexists the condition of anophoria, that is, if the eyes point too high, quite important modifications of the declination can be accomplished while depressing the plane of vision. Let a case be supposed in which there is upward rotation by the tropometer of 40° for each eye and a downward rotation also of 40° . The declination is: right (—) 3° , left (+) 5° . The problem is to reduce the declination. It will not only be safe but much to the advantage of the patient to reduce the upward rotation to about 36° or 37° and increase the downward rotation in proportion. This will mean a graduated tenotomy of the superior rectus of about 6° or 8° of prism. Experience has shown that it is prudent not to attempt to bring about such a relaxation of the superior rectus tendon as to induce, after the tenotomy on the first eye, as much as 10° (prism) hyperopia. A relaxation of 6° (prism) or possibly a little more is within the limit of safety.

In the case supposed, then, we may relax the superior rectus of the left eye, *releasing the attachments of the tendon at its inner border only*, leaving the external border to a considerable extent intact. This depresses the eye somewhat and tilts it toward the centre. If we do not induce a right hypertropia of more than 6° by this, we are likely to find, later, that we have effected a correction of at least 2° or 3° of declination. This, though less than a complete correction, is an extremely important one. We may now, using a prism to neutralize the hypertropia, ascertain by the aid of the clinoscope whether the (—) 3° declination for the right eye remains. When the negative declination is but slight in such cases, it sometimes disappears after the partial or complete correction of the larger positive declination, a fact which suggests that the lesser negative anomaly may in some cases arise from a synergetic tension of the muscles in association with those of the other eye, and it also indicates the propriety of attending first to the side which has the greater degree of the defect, which is almost invariably the positive.

Should the declination be found still to exist in the right eye, as at first, a relaxation for the correction of the induced hypertropia is to be done, this time, however, carrying the relaxation toward the outer border of the insertion, leaving the inner border intact. It is advisable sometimes to defer the second operation till the following day, in order to make sure of the position of the meridians. The procedure described has served to bring relief in very many cases, and it is the most simple, easy, and uncomplicated of all the measures at our disposal.

On the other hand, if there is katotropia, the inferior tendons may be treated on the same principles. It

ould, however, be strongly impressed upon the mind of the surgeon that of all the recti muscles the inferior are infinitely more subject to unpleasant disturbances of their action from surgical interference than any of the other eye muscles. It is better not to disturb the action of these muscles except when the upward rotation is markedly below the standard, and then a relaxation of from 3° to 5° is all that is usually safe. At the risk of repetition, let me advise the surgeon to exercise the greatest prudence and conservatism in regard to operating upon the inferior recti.

It might be assumed that, acting on the same principles, we might, in a case of esophoria without anisophoria, relax the upper or lower half of one or other or possibly of both internal recti muscles, and that a like procedure might be adopted for exophoria. As a matter of fact, since the study of declinations has been carried to practical extent it is found necessary to operate directly for esophoria or exophoria much less frequently than before, and, as a rule, such direct operations should be avoided. If the excess of upward or downward rotation of the eyes is eliminated and the declinations are corrected, the heterophoria is likely to disappear, and it is doubtful whether, if an ideal correction of the two conditions named could always be accomplished, there would in any considerable proportion of cases be occasion for operating for heterophoria.

With the view, then, of preserving as nearly as possible the full and equal rotation action of the lateral muscles and at the same time avoiding any raising or lowering of the plane of vision when such change is not, irrespective of other conditions, required, I have resorted to several methods of procedure, each progressively more effective than the other, until at present only one of these methods is employed, except in cases such as I have already described. Although the earlier methods have been superseded, it will be well to pass in review the process of evolution of the more effective operation for declination.

EARLIER OPERATIONS.—The first of these was the operation, a description of which I published a few years since and called *peri-tenotomy*. It consisted, essentially, in relaxing a part of the insertion of opposing muscles at diagonally opposite points. Thus, if the lateral muscles were selected for operation for positive (+) declination, the upper half of the externus insertion and the lower half of the insertion of the internus were relaxed. By this means about 1° or possibly 2° declination could be corrected, but the change of direction of the meridian of more than 1½° required an extent of relaxation of the tendon insertion which threatened restriction of the action of the muscles. Practically, then, a correction of 1° or a little more was all that could be hoped for with a conservative operation.

The second step in the evolution was the operation which I called *circumtraction* (vertical or lateral). In this procedure a part of the insertion of opposing muscles

was separated from the sclera, and this separated part was carried forward into a previously prepared pocket, thus advancing, for example, the upper half or two thirds of the insertion of the internus and the lower half or two thirds of the externus. By this method a correction of a larger degree of declination could be effected, but here again there was danger of inducing a disproportionate action among the muscles.

The third step in the evolution of an operation for directly affecting declination is what I have termed *extendo-contraction*.

EXTENDO-CONTRACTION.—By this operation the full rotation action of the muscle is preserved, no heterophoria is induced, eyes which were parallel before the operation remaining so after it, while by its means a greater degree of correction of the leaning of the meridians can be brought about than by either of the preceding measures. Even by this process a change of the direction of the meridians of 2° or 3° must be considered a favorable result, although occasionally a much more important change is effected by a single operation.

In cases of high degree of declination the operation

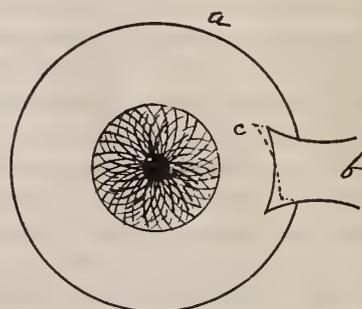

FIG. 8.—Diagram illustrating the change of the line of insertion of the tendon of the internus.

may be done on one muscle at one time and on another at another time. The selected muscles are the internus and the superior.

Of course it may be done on the externus and inferior, but it has been found prudent to avoid operations on these muscles as far as possible. As it is not an easy or simple process, I shall describe it in detail, premising that it is of the highest importance that the various steps should be taken exactly in the order and in the manner described. Let it be assumed that the internal rectus of the left eye has been selected for the operation on account of a + declination 4°. The surgeon, standing on the right-hand side of the patient, the lids being separated by a specu-

FIG. 9.

lum, the patient is told to direct the eyes to the left and down. Then the surgeon, seizing a very small fold of the conjunctiva (1 millimetre) by the fine forceps (Fig. 9), makes an opening with the fine-pointed scissors (Fig. 10)

just over the upper border of the insertion of the muscle, and, pushing the blades of the scissors forward while avoiding, so far as possible, enlargement of the small opening in the conjunctiva, he forms a pocket nearly up

FIG. 10.

to the border of the cornea and extending more than half-way down the length of the tendon insertion.

The pocket being made, the operator next passes to the left side of the patient. He now seizes the insertion of the tendon at its upper part in the fine blades of the forceps and separates it to the extent of a few millimetres only. He then introduces the delicate sharp hook (Fig. 11) between this separated part and the sclera and,

FIG. 11.

when it has been carried back to the desired extent, presses the sharp point against the inner surface of the tendon and draws it forward. The hook should engage itself sufficiently below the border of the tendon and sufficiently back to insure the drawing forward of that part of the tendon. The part of the tendon engaged by the hook is now forced through the little opening in the conjunctiva, when a small curved needle, one of two attached to a very fine thread, is carried through the protruding portion of the tendon, which is then allowed to retreat within the conjunctiva. An assistant takes the two needles, holding the thread out of the way of the operator, who now, using the small tenotomy hook (Fig. 12), divides

FIG. 12.

the remainder of the insertion with care not to enlarge the original conjunctival wound. If the tendon is unusually broad, a counter-opening near the lower border of the tendon is made, and the division of the tendon is completed from this point. The extent of the division is ascertained by the phorometer before the next step is entered upon. If 10° or 12° exophoria has been induced the lower border of the tendon is free.

The assistant now inserts a director through the conjunctival wound into the pocket, carrying it somewhat above the border of the cornea. One needle is carried in the direction of the probe, making its exit above and near the border of the cornea. The second needle is then carried through 3 or 4 millimetres below, and the thread is drawn and tied in a slip-knot. An esophoria of about 5° should be induced. If more than this has been brought about, the thread must be loosened until the

amount does not exceed 5° . Then the knot is made fast and the thread is cut. The thread should be extremely fine, of silk. No catgut is sufficiently delicate for the operation.

On the following day there should be neither esophoria nor exophoria, and there will, if the operation has been skilfully done, be no apparent wound of the conjunctiva, though there will, of course, be redness and some slight thickening.

By referring to the diagram (Fig. 8) an idea may be acquired of what is to be accomplished by the operation. The equator of the eyeball is indicated by *a*, and the tendon of the internal rectus by *b*. The solid line represents the direction of the insertion of the tendon before the operation, while the dotted line represents the position of the insertion afterward.

It will be seen that the extremity of the tendon at has been advanced toward the cornea, while the lower extremity has fallen somewhat back, giving the insertion an oblique direction. The result of this oblique direction should be to influence the vertical meridian to lean from the left farther toward the right.

GENERAL CONSIDERATIONS.—Various modifications of the methods of operating above described will occur as occasion may require, to one who has a thorough comprehension of the principles involved. From what has been stated regarding the relations between declinations and strabismus the suggestion might occur to some that there is in this presentation a claim that the empirical method of treatment for strabismus can be entirely abandoned, and that the defect may be treated entirely or what I may term the rational ground of removing declinations and correcting excessive or restricted vertical rotations.

It would be extremely fortunate if this view could be maintained, but, unfortunately, at least for the present the empirical methods cannot be absolutely discarded. They may, indeed, be greatly modified and in many cases the rational methods may be successfully employed alone. There are, however, in a certain pretty large proportion of cases difficulties in the way of such rational treatment exclusively which cannot be wholly overcome. In many cases of strabismus it is quite impracticable to determine the direction or degree of declination. It may be even impossible for the patient to locate in space the projection of any image. My own practice with such cases has been in the milder instances of strabismus, where more or less satisfactory conclusions can be reached regarding the underlying conditions of the defect, to direct the treatment to these conditions so far as they can be ascertained. In many instances, when a beginning has once been made, the conditions become more evident and gradually a full correction can be made on entirely rational lines.

In the more extreme cases I have employed the empirical method to the extent of relieving in some measure the extreme convergence or divergence in order that some,

at least approximate, tests can be made. Following this, the method which I am here calling the rational method may be substituted, and eventually a full correction of the squint may be made without the disability which invariably follows a complete tenotomy with recession of any eye muscle. Thus by a prudent and considerate employment of the empirical in connection with the rational method a radical and most important advance can be made in the treatment of these defects.

In the lesser cases, heterophoria, more patience may be required in arriving at a nominal correction by attending to the underlying conditions than would be in the more direct method. The results of the former method are so infinitely better and so much more apt to be permanent that there should be no hesitation in regard to the choice of methods.

As to the maladies which are so often associated with heterophoria and to which so great, even surprising, relief is often come from its correction, even more satisfactory and far-reaching results can be looked for when the essential element, not only of the heterophoria, but of the malady, is removed.

THE RELATION OF SCURVY TO RECENT METHODS OF ARTIFICIAL FEEDING.*

By J. P. CROZER GRIFFITH, M. D.,

PHILADELPHIA.

In spite of the amount of careful study spent upon the cause of infantile scurvy and its relation to it, it still possesses many points of obscurity. Some cases would appear to make all clear, were it not that others seem totally to controvert their evidence. Yet there are certain conclusions which we are justified in drawing regarding the relationship which artificial feeding bears to the disease.

I wish to use for the purpose of formulating them, the report of the committee appointed by the American Pædiatric Society; II, my own individual experience in a number of cases. Upon the study of the very numerous cases reported in Europe I will not enter.

I.—Two years ago the American Pædiatric Society made and published, as you remember, an extensive collective investigation of infantile scurvy as it occurs in North America. It has been a general source of disappointment that the committee in charge did not feel able to express more positive conclusions regarding the ætiology. Having been a member of this committee, I may now, in my capacity as an individual, express the belief that the tabulated cases admit of a step further in the way of conclusions than the report went—no absolute conclusions, so far as data go, but such as are almost as nearly true, and which are very suggestive.

There were 379 cases of scurvy reported to the committee. In 356 of these the nature of the diet was speci-

fied which the child was taking when the disease developed. In 214 cases, *i. e.*, 60 per cent., the food was a proprietary one. In by no means every one of these can the disease be certainly attributed to this cause, since in some instances sterilized milk or some other article which has been suspected ætiologically had been added. Yet the percentage is so high that there can be no question about the influence of proprietary foods, even if it had not happened that in a large number of instances proprietary food alone was employed. Thus, forty-four children, 12 per cent. of those studied, received one of the malted foods alone without any milk, and thirty-two (9 per cent.) were fed purely on condensed milk.

Food containing or derived from starch seemed to be a powerful ætiological factor, especially if we include many of the proprietary foods. At least between fifty and sixty children had insoluble starch in their diet, twenty-four of them deriving it not from proprietary foods. If, now, we add to these those who received starch partially or wholly transformed, and the twelve children who received "table food" (probably chiefly starchy) in addition to milk, the total number receiving starch equals over two hundred, *viz.*, 56 per cent. I do not for a moment wish to intimate that this is positive proof that starch in any form causes scurvy. It does, however, cast a grave suspicion upon it, which may well influence us in our treatment of the disease.

Finally, the use of cooked or partially cooked milk seemed to have an undoubted influence in a number of cases. In sixty-eight cases, *i. e.*, 19 per cent., sterilized milk was the only food given, and in a large number more it was one of the ingredients of the diet; making, at the least, 107 cases in all, or 30 per cent. In sixteen cases (5 per cent.), pasteurized milk was the only food used. This is weighty inferential evidence that the cooking of milk is to be suspected as a cause of scurvy in infants. Yet it is not positive proof, since in so many cases some proprietary or starchy food was combined with the milk, and even in those in which sterilized milk was used alone we do not know but that the proportions of proteids, fat, and sugar present were entirely faulty. It is interesting to note that several children were attacked with the disease while on a diet of raw milk, and ten while on one of breast milk alone—an indication that a fault in the proportions of the constituents is to be sought for.

Still more useful in studying ætiology is the consideration of the effect of dietetic treatment in the collected cases. Just here there exists, however, one very great difficulty, *viz.*, that in the use of fresh fruit juice (which for convenience I am speaking of as a medicine and not as a food) we probably possess such a rapid and certain specific for the disease that it is generally impossible to determine, when this treatment is used, exactly what influence the accompanying change of diet may have exerted. The converse of this is, of course, also true, that the exact value of fruit juice cannot be

*Read before the New York Academy of Medicine, October 1, 1900.

determined when a proper alteration of the diet is made, for rapid recovery will follow in that event also. In fact, in only three cases could we learn that fruit juice was employed alone. The spirit of humanitarianism prevailed over that of scientific research in the great majority of physicians from whom we derived our cases, for in 257 out of 326 cases suitable for study a mixed treatment of fruit juice and change of diet was employed. The children probably were benefited, but the investigation suffered. Omitting for the moment the consideration of this group of *mixed-treatment* cases, we still have fifty-eight cases in which a change in diet *without* the use of any fruit juice gave a successful result. Among these we find recovery following the abandonment of proprietary foods, alone or in combination, in thirty-four cases, including six cases solely on condensed milk. It occurred in eighteen cases in which a diet of sterilized milk alone had been abandoned. In six or seven cases the doing away with food containing unconverted starch was successful, and in nineteen cases this statement applies to food containing converted starch. Curiously, we note one case of recovery after change from breast milk to sterilized milk.

Among the 257 cases of mixed treatment we find recovery following, in twenty-three, the abandonment of condensed milk alone, and in nineteen others that of condensed milk in combination with a malted food. In eleven cases recovery followed the change from a food containing insoluble starch, and in sixty-one that from one containing converted starch, making seventy-two in which the food was made from starch, or ninety-one in all, if we add in the nineteen cases in which condensed milk and a malted food were used together.

There were probably forty-three cases in which recovery followed the giving up of milk which had been sterilized, or, in a few cases, pasteurized. Probably this number should be greater, as it is likely that the milk added to some of the proprietary foods was cooked in the course of preparation.

It must be remembered that in all the cases of this division fruit juice was given during treatment. Consequently they are not offered as actual proof of a therapeutic action of diet. They are suggestive merely.

II.—*Personal Cases.* The experience of one individual, although limited, has sometimes the advantage that details are known which are often wanting in a collective study. Omitting reference to earlier cases, I have had under my care in the last eighteen months or so sixteen cases of infantile scurvy. As I hope to publish a fuller account of these later, occasion will be taken here to give only the briefest synopsis of the diet at the time the disease developed and of the treatment employed. In all, recovery was prompt.

CASE I (B.).—*Diet*, a proprietary food added to milk which was scalded only. *Treatment*, orange juice, raw milk, withdrawal of the proprietary food. *Note.*—Disease scarcely due to the slight heating.

CASE II (C.).—*Diet*, a proprietary food and sterilized milk. *Treatment*, raw milk, orange juice, withdrawal of the proprietary food.

CASE III (McN.).—*Diet*, a proprietary food and sterilized milk. *Treatment*, raw milk, orange juice, cessation of the proprietary food.

CASE IV (F.).—*Diet*, a proprietary food and milk, heated, but not to boiling. *Treatment*, orange juice, withdrawal of the proprietary food, milk to be warmed only. *Note.*—Disease not accounted for by the slight heating.

CASE V (T.).—*Diet*, a proprietary food. *Treatment*, orange juice, scalded milk, withdrawal of the proprietary food. *Note.*—The use of partially cooked milk did not interfere with recovery, which seemed clearly due to the proprietary food.

CASE VI (A.).—*Diet*, sterilized milk with dry malt extract. *Treatment*, orange juice, raw milk, withdrawal of malt extract. *Note.*—Sterilization probably the cause.

CASE VII (W.).—*Diet*, a proprietary food and sterilized milk; beef juice. *Treatment*, orange juice, pasteurized milk, withdrawal of the proprietary food. *Note.*—The use of patented starchy food seems the cause here.

CASE VIII (McC.).—*Diet*, a proprietary food and sterilized milk. *Treatment*, orange juice, beef juice, raw milk, withdrawal of the proprietary food.

CASE IX (McC.).—*Diet*, a proprietary food and sterilized milk. *Treatment*, orange juice, beef juice, raw milk, withdrawal of the proprietary food.

CASE X (McC.).—*Diet*, a proprietary food, or possibly raw modified milk with very low percentages of fat and proteid, and with barley water added. *Treatment*, orange juice; no change in the modified milk mixture. *Note.*—The uncertainty as to the cause is due to doubt regarding the date of the first symptoms. I believe the disease developed while the proprietary food was being given, but in that case the symptoms grew worse on the low-percentage modified milk mixture, and improved in spite of it.

CASE XI (J.).—*Diet*, raw modified milk with barley water. (F. 3, S. 7, P. 1.50 at seven months) *Treatment*, orange juice; beef juice; increase of proteid to 1.75; pasteurization of the mixture; withdrawal of barley water. *Note.*—The formula seemed satisfactory; the proteids not especially low for the age, and their increase during treatment was inconsiderable. The commencement of pasteurization did not interfere with recovery. One is led to suspect the barley water.

CASE XII (C.).—*Diet*, pasteurized modified milk with barley water (proteids 1.25 at ten months) *Treatment*, orange juice, no change in diet. *Note.*—I have looked upon the low proteid percentage as the cause. Yet both this and the pasteurization are still being used.

CASE XIII (S.).—*Diet*, a proprietary food and scalded milk. *Treatment*, withdrawal of the proprietary food, milk still scalded; later, orange juice. *Note.*—Improvement began when the proprietary food was withdrawn before the use of orange juice was commenced. Patented food must be considered the cause.

CASE XIV (F.).—*Diet*, sterilized milk (2½ per cent proteids at nine months). *Treatment*, orange juice, sterilization stopped. *Note.*—No cause but sterilization discoverable.

CASE XV (P.).—*Diet*, raw modified milk with proprietary food added. *Treatment*, withdrawal of the

proprietary food. *Note*.—No cause discoverable but the proprietary food.

CASE XVI (W.).—*Diet*, raw modified milk with barley water (proteids 1.5 per cent. at nine months). *Treatment*, orange juice; no change in food. *Note*.—Possibly too low a proteid percentage may be looked upon as the cause. Possibly barley water is to be suspected. Yet recovery went on in spite of no change in diet.

Without entering upon an analysis of these sixteen cases, I wish to indicate certain points of interest. Nearly, the cases support the generally accepted view that the patented foods often produce infantile scurvy, and some of them show that recovery may follow the withdrawal of these foods without other treatment. Whether this is because they are deficient in certain ingredients, or whether it is the fact that they so commonly contain or are derived from starch, remains to be determined. Two of my cases throw suspicion on barley water.

The cases indicate, too, that the sterilization of milk as an undoubted power to produce scurvy, but that this is a less prominent ætiological factor than the last. In fact, one of the most striking features which the cases illustrate is that scurvy can readily develop on a diet of milk which is not long heated, or which is even raw. In some such instances we are led to suspect the action of a low percentage of proteids. Some of the cases also show that the beneficial action of fruit juice may begin and continue without any change in the food whatever. This is perhaps a valuable point, because in the 379 cases collected by the committee there were only three which illustrated this fact. It is also important because it teaches that we must not always hasten to change the diet which has seemed to agree with a child with weak digestion, because symptoms of scurvy are appearing. Better far in most cases the danger of the development of a disease generally easily curable, produced possibly by a low proteid percentage, than to incur the far greater danger of a wasting diarrhœa or other digestive disturbance, the result of over-strong food.

In closing, I would only say that an extended study of the subject has convinced me of one thing especially, viz., that whereas there are classes of foods which are particularly apt to produce scurvy in infants, yet the individual element is remarkably present in this disease. It is especially true here that what is one baby's meat is another baby's poison.

123 SOUTH EIGHTEENTH STREET.

THE PATHOLOGY OF INTRA-UTERINE DEATH.

By NEIL MACPHATTER, M. D., C. M., F. R. C. S.,

NEW YORK,

VISITING SURGEON, POST-GRADUATE HOSPITAL.

THE uterus may be considered an accumulation ofumbering cells which nothing can awake but the knock of a fertilized ovum. Such an ovum, however, is not without its troubles and dangers. It is the determination to investigate in some kind of a systematic way the

various influences which may be considered detrimental to its growth and development. In looking through the literature of the subject it is somewhat astonishing to find so small a number of writers upon so vital a matter. Here and there are a few desultory remarks, but they are mainly fragmentary. When viewed from all the transcendent sequelæ following in its wake, the morbid processes linked and entwined about the embryo become of the utmost importance to the physician, the pathologist, and the public. Fortunately for mankind, more particularly for those who are obliged to bear the burdens, cares, and dangers of parturition, Nature, in her own inimitable ways and by ordinances which far surpass in beauty and perfection of design the imagination of man, is usually quite willing and competent to fulfill these functions in a normal and satisfactory manner. Occasionally, however, the ordinances of Nature become disregarded.

Morbid influence in the uterus, the embryo, or its appendages, or general or local constitutional perversions, may render it absolutely impossible for a viable fœtus to be born. Frequently the physician is confronted with the proposition of how such a calamity can be obviated. It is a question eminently worthy of the conscientious consideration of the profession. Brothers have gripped and throttled each other in death's grim grasp, family ties have been severed, estates have changed their line of descent, kings and princes have fallen, governments have been overthrown, wars have been waged, and dynasties have ceased to exist because some morbid pathological process has disarranged the physiological development of an embryo. Apart from such serious disasters, the death and expulsion of a fœtus may be regarded as an affliction both to the mind and constitution of the mother. Many of the disastrous consequences which ultimately lead to deteriorated health or chronic invalidism can be clearly traced to reiterated abortions. When yet the fœtus is in the early stage of development the intimate anatomical relationship of the parts renders the opportunities for deviations from normal conditions extremely frequent. From the time in which the pronucleus of the male meets and bores its way into the ovum, and there the two fuse together, until the full development of the fœtus and its various membranes, there are ever-varying and constant changes in progress.

An investigation into all the conditions and the various circumstances leading up to and producing intra-uterine death is surrounded frequently by innumerable difficulties. Not alone does it require minute investigation into morbid constitutional deviations from health on the part of the woman, but what is probably not sufficiently understood is the fact that the male parent may be the cause of the inability of the mother to carry the fœtus to the full term of gestation. Besides these, such an investigation involves the various morbid changes which so frequently take place in the uterus, placenta, foetal membranes, or embryo.

It cannot be too strongly emphasized that frequently the causes, directly or more remotely, which ultimately bring about the death and expulsion of the foetus are extremely difficult to detect. It is not an unusual occurrence for a woman apparently in the midst of health, and surrounded by all the comforts of home and environment, to abort in each successive pregnancy. In some women there exists such a tendency to miscarriage that almost any indiscretion is sufficient to cause a detachment of the ovum. The reverse of this, however, is not unusually seen. Women who are apparently no healthier than their more unfortunate sisters may be submitted to almost any amount of violence without in the least interfering with the progress of pregnancy. This is evidenced in women who have accidentally fallen out of windows or who have been thrown from carriages and those who have been forced to jump from burning buildings, and, although legs and arms have been fractured, they have recovered without aborting.

When the intricate anatomical superstructure of which the uterus is composed is in a healthy normal condition and the vitalizing products of the male and female possess sufficient inherent power to carry on gestation, pregnancy progresses in an uninterrupted manner unless some subtle influence interferes.

When such an ovum reaches the uterus, the decidua hastens to envelop it in its mantling fold of welcome. The latent cells and fibres of the uterus receive with glad acclaim the advent of a new life and with characteristic and marvellous harmony advance in size and function to meet the necessities for the progressive and incessant changes which are constantly to take place, for already a new life is under the watchful care of the vestal angels of heaven. The intra-uterine dangers and vicissitudes of such a foetus become singularly interesting to contemplate.

Pathological researches into the various causes which may lead to the expulsion of a foetus, although conducted by many eminent minds, are extremely difficult to trace in many instances. In the later stages of gestation the investigation is frequently not so uncertain, but in the earlier stages, when the delicate tissues are so fragile, the task is extremely confusing. The particular period of child-bearing life at which abortions take place has given rise to difference of opinion by equally conscientious and painstaking investigators. A number regard the risk greater in first pregnancies, especially among the better classes. The customary habit of these people of taking long journeys after marriage has a tendency, if pregnancy results, to breaking down conception as a result of fatigue and the extra amount of irritation incurred as a consequence of licensed opportunity and pent-up desire. Whitehead and others maintained that third and fourth pregnancies were the more liable to be unsuccessful. He interrogated no fewer than 2,000 young pregnant women whose ages averaged about thirty years.

He found the number of their pregnancies to be 8,681 or 4.34 each. No fewer than 1,240 had aborted. The accuracy of these figures, as giving the average number of miscarriages for the whole child-bearing period should not be accepted unreservedly. They are admittedly the number of abortions for the stated number during the first half of the reproductive period of a woman, and, inasmuch as miscarriages are more frequent in the latter half of the child-bearing period, the statistics of Dr. Whitehead are on this account below the average. This can be demonstrated by any one who wishes to investigate the subject closely. Priestley's figures may be considered as accurate as any, and, as they are free from the thralldom of preconceived ideas, there is no hesitation on my part in giving the results of his inquiries here. He started on the data secured from 1,000 private patients. The accounts given by many of these patients were so untrustworthy or so vague as to be absolutely unreliable. Out of the number, he selected the histories of 400 which were distinct, reliable, and unequivocal. The results are interesting, for they were taken in all cases in women who had reached at least forty years of age. These 400 women had been pregnant 2,325 times. There were 542 abortions and 1,783 living children. The number of abortions, according to these statistics, is considerably higher than the figures of Whitehead. They, however, embrace practically the whole period of child-bearing life, while the former's investigations are limited to women below the age of thirty years. The ratio of abortions to live children, according to these figures, is very nearly one to three. Of these women, 152 had no abortions, while 27 out of the 400 had abortions only.

AN ANALYSIS OF A NUMBER OF WOMEN WHO HAD AND WHO HAD NOT ABORTED.

	Percentage.	Being about
Ratio of abortions to pregnancies...	23.32	1 in 4 $\frac{1}{3}$.
Ratio of abortions to children....	30.40	3 $\frac{1}{3}$.

A study of these tables is interesting and peculiarly instructive. The first demonstrates the fact that those under thirty years of age aborted in the proportion of about one in three; whereas among the older women the abortions were at the ratio of two to one. The next table demonstrates that the second period is more productive of pregnancy than is the first in the proportion of 5.81 to 4.34. It illustrates, too, the point that in them the tendency to abortion is also greater in the ratio of 23.32 to 14.08. If these calculations are approximately correct, the number of foetal deaths throughout the United States is something enormous and well worthy of a careful investigation by the profession.

There are probably two periods during intra-uterine gestation when the death of the foetus is most apt to occur, viz., the first few weeks of pregnancy and, again, about the third month. In the early weeks the foetus is so fragile and its attachments are so delicate and tender that the least deviation from normal conditions, either local or constitutional, is sufficient to cause its detachment and expulsion. For obvious reasons it becomes practically impossible frequently to determine the presence of an ovum in the discharge that may escape. Not unusually the ovum may become dissolved and nothing can be seen but a small clot of blood, with no semblance of a foetus discernible. One of the cardinal reasons for such a result is no doubt some faulty condition of some of the foetal envelopes. It must be remembered that the decidua begins to form just as soon as a fecundated ovule reaches the uterine cavity. This consists of the mucous membrane of the uterus itself, thickened and changed, so as to form the outermost of the various coats that normally cover the foetus. It occasionally occurs that a membrane in every respect similar to that of a decidua is formed in the unimpregnated uterus. More frequently about the uterus than in any other organ of the body, the decrees which govern its various functions become estranged, the control of its formative elements becomes lost, perversions of physiological acts result, and so it

comes about that the latent cells of the mucous membrane in some misguided way form a phantom decidua and then lie down and die. This spurious membrane is sometimes expelled at a catamenial period and gives rise to an unusual amount of pain. The occurrence is generally known as membranous dysmenorrhœa. When such a condition occurs repeatedly in a married woman there is good reason for believing that it is the result of conception. It is not unusual for such a membrane to be extruded quite frequently during the continuance of marital relations, but for the expulsions to cease suddenly when coitus is held in abeyance. This subject will be more fully discussed when speaking of the pathology of the foetal membranes. It is here mentioned to emphasize the importance of recognizing the condition as a frequent cause of abortions in the early weeks of pregnancy. Among other reasons for early miscarriage may be mentioned a lack of vitality in the spermatozoa.

When pregnancy has successfully passed the dangers to which it is liable during the early days and weeks, there comes the period at about three months when other dangers may appear, and this may be considered the second most frequent dangerous epoch. There are valid reasons why this should be so. About this time the young placenta is beginning to assume a definite form. The decidua serotina is fairly large and the villi of the chorion have by this time become more concentrated throughout its surface. The vascular structures in the tissues are in a state of formation and transition, and the tender anastomotic loops from the maternal circulation are beginning to zig-zag their way in and around the foetal villi like delicate webs, as if in wonder where to go. There is a certain degree of insecurity in these fragile structures and a great liability to hæmorrhage and extravasation of blood between the decidua reflexa and the chorion during this time.

With these necessary preliminary remarks, and without any further skirmishings, I propose now to investigate the most important causes which may give rise to the expulsion of a foetus. No definite classification will be followed, other than that the causes referable to the father will first be considered, after them general constitutional reasons attributable to the mother, and lastly those more particularly relating to the foetus and its various membranes.

CAUSES ATTRIBUTABLE TO THE FATHER.—That the death of the foetus or the inability of the mother to carry the foetus is sometimes owing to a defect in the male parent, all authorities concur. If closer investigation were made of these cases, there is every reason to believe that the fault would be more frequently found referable to the father than is universally believed. The father may be too old or too young to impart the essential potency to the fecundating fluid. Certain diseases may have a similar effect, and, while it is possible for conception to take place under these circumstances,

there is not the necessary amount of vitality to continue the development of the product, and so it droops and gradually withers away. A similar condition is frequently to be seen in eggs and in plants. Birds are often unable to hatch out their eggs, although there is no apparent defect in them to be discovered. There is in all likelihood an imperfect impregnation on the part of the male. Plants are singularly prone to be affected in the same manner. Here the pollen may be defective or its vitality impaired by some unknown cause before it reaches the pistil. The result may be the formation of a seed, but it is of such a low order of vitality that it does not possess a sufficient amount of inherent energy, and the consequence is an imperfectly developed seed which never reaches maturity.

It can be stated with a degree of probability amounting almost to a certainty that the power for procreation is manifestly distinct from that of development. A man may have lived a life of debauchery and have suffered from the diseases from which men suffer to such a degree as to vitiate his whole constitutional powers, and as a consequence impair his procreating powers to such an extent as to be incapable of producing healthy vitalizing spermatozoa. Again, a man may be capable of fertilizing an ovum, but his whole energy may be expended in the effort, so that none remains for future development, so far as he is concerned. The power of development may be relative. A delicate, puny man may possess sufficient energy to impregnate a healthy, robust woman, and, inasmuch as she possesses a superabundance of strength, the life of the ovum may in future be carried on altogether under the vital energies of the mother.

It has been demonstrated conclusively that a woman may abort consecutively and yet be potentially fertile. The fault here lies in the fact that the husband, although physically in robust health, yet may have spermatozoa of so low a degree of vitality as to be incapable of continuing conception. Occasionally this defect may be congenital, but more frequently it is acquired. When the formation of spermatozoa and the distance they are obliged to travel before they finally nestle down in the seminal vesicles are considered, it is astonishing that they are not more frequently impaired. They are formed in the convoluted tubuli seminiferi in the substance of the testicle. It is a disputed point as to the length of these miniature tubes, one authority stating that their average length is about two feet and a quarter and the tubes themselves numbering over 840. Others maintain that they are over sixteen feet and number 300. Whichever statement is correct matters very little practically. They consist of a membrana propria, and in the inside wall of this membrane is an epithelial lining, from which spring the seminal cells. The nucleus of these cells is in a constant state of division, and as a consequence of this a number of daughter-cells can be seen forming. These small daughter-cells are known as spermatoblasts, and by a process of change ultimately become spermato-

zoa. In certain parts of these tubes the broad, expanded end may be seen elongating into the middle part of the spermatozoon, while the nucleus forms the short, thick head. A thin, long part of the epithelium projecting into the lumen constitutes the tail. After these minute bodies are formed they pass through the vasa recta, the rete testis, the vasa efferentia, the coni vasculosi, the epididymis, and the vas deferens before they finally lodge in the seminal vesicles, there to remain until copulation ejects them into the vagina.

Certain malformations or diseases of these parts may so cripple their function as to render them unfit for the development of healthy spermatozoa. The testicle arises from the inner concave disc of the Wolffian bodies, or, as they are frequently termed, the primordial kidneys. They therefore have their beginning in the abdominal cavity behind the peritonæum. The vasa efferentia, the coni vasculosi, and the globus major are not, however, produced from the Wolffian body, but very close by, and form a distinct cell mass. Until about the sixth month of foetal life the testicles are situated below the kidney. They gradually descend so that at the end of the seventh month they are at the internal abdominal ring, ready to advance down into the scrotum. In the elephant and some other animals they remain permanently within the abdominal cavity, while in the *Rodentia* they descend only at the "rutting" season. It occasionally happens in the human subject that they are retained in the abdominal cavity, and there they are so imperfectly developed that the spermatozoa which they form are so greatly defective that, should impregnation take place, it but rarely goes to maturity. It is well, therefore, in investigating the causes of intra-uterine death, to examine the male parent for non-descent of the testicle.

Orchitis.—Inflammation of the seminal gland, either acute or chronic, not infrequently leaves as one of its results the testicle so damaged as to be unfit to elaborate spermatozoa of sufficient vitality to carry on conception. The pathology of such a condition is similar to that following an inflammation of any other part. There will be a general infiltration with a considerable amount of organizable material throughout the whole gland. This inflammatory effusion, which usually consists of fibrinous exudation, insinuates its way around and between the secreting tubuli. When this material is poured out in considerable quantities, its complete reabsorption is almost impossible. As a consequence, the subsequent integrity of the organ will become impaired as the result of the gradual contraction of the fibrous exudation that has not become absorbed. More or less atrophy of the testicle results and the delicate tubuli will suffer in proportion.

Syphilitic inflammation of the testicle has probably a greater tendency to be followed by deposit of fibrous exudation than other varieties. Nor is this to be wondered at, for we see it manifesting itself in this manner throughout the different structures of the body. I sha

have more to say about syphilis as a frequent cause of abortions in a later portion of this article.

Tuberculous Disease of the Testicle and Seminal Vesicles.—The slow, quiet, and insidious manner in which tubercle may affect the glandular structure of the testicle, epididymis, or seminal vesicles is an element of singular interest in its effects upon the progress of pregnancy. Tuberculous disease usually manifests itself in the form of miliary tubercles, when the symptoms will be indefinite for a long time or until disorganization begins. The infiltrated organ has but little power in resisting an acute or chronic inflammatory process, and, as a consequence, caseation and ultimate disorganization inevitably follow. During these several changes there is a period in which the secretion of seminal cells, with their later changes into spermatozoa, is going on, but they are necessarily so weak and delicate that, should they possess sufficient strength to impregnate an ovum, it would not have that amount of inherent vitality to carry it on to the full term of gestation. Active epididymitis is frequently caused by some local injury or the wearing of a badly fitting truss, but more frequently is a consecutive affection resulting in association with acute or latent gonorrhœa. Sometimes it follows as the result of cystitis or the irritation of a calculus in the bladder. In these cases the inflammatory process gradually extends along the vas deferens to the epididymis, and generally does not reach the seminal gland, but limits its action to the convoluted tubes of the seminal duct. The disease generally comes on quite suddenly and there is distinct enlargement in the epididymis. There is tenderness traceable along the cord. As a result of this condition, it is quite frequent to have the small, tortuous ducts so distorted and thickened by the inflammatory process as to render their function greatly impaired.

Of all the causes which produce intra-uterine death, none is more potent than the poison of syphilis. It is universally accepted that a man afflicted with syphilis may communicate the disease to the woman during coitus. A local indurated sore is the immediate result, followed later by a dissemination of the virus to all the great centres of life. In this contamination the ovum participates, and is, as a consequence, blighted. It may not, however, be generally known that a man who has become infected with syphilis, but who has got rid of his initial sore, but who, nevertheless, has yet the syphilitic virus in his spermatic fluid, may marry and have intercourse with a woman without infecting her. Should pregnancy take place, the spermatic fluid may contain such a quantity of the virus that conception breaks down, and the poison of the fœtus would then be the carrier into the maternal blood and give rise to general constitutional syphilis. The reason for this is probably the fact that there is no direct vascular communication between the fœtal circulation and that of the mother during intra-uterine life. The sinuses of the placenta contain maternal blood, which is carried there by the uterine

arteries. There is a corresponding number of uterine sinuses which carry the blood away, but during the time in which these sinuses are filled with blood the miniature loops and tufts of the fœtal blood-vessels are lying so close to them that only the thinnest possible membrane intervenes. It is through this delicate structure that the oxygen and other nutriments pass from the maternal circulation for the nourishment of the fœtus, and carbonic acid, urea, and other waste products pass from the fœtus to the mother. The exchange is brought about by osmosis and is quite similar to the exchange of oxygen for carbonic acid in the lungs. So long as the integrity of the parts concerned in this process is maintained, it is difficult to conceive of how the mother could become contaminated by the virus of syphilis. Should, however, the product of conception become disorganized, then absorption from the dead fœtus would syphilize the mother. The fact that a syphilitic fœtus could develop without directly transmitting the virus to the mother was disputed for a long time, but the argument has been clearly sustained and is now almost universally accepted by the profession.

In the tertiary stage of the disease, it is extremely doubtful if coitus without conception will impart a venereal taint to the woman, but there is very cogent evidence to substantiate the assertion that the mother can be contaminated through the medium of the fœtus. It frequently happens that a man may submit to a course of treatment after having contracted syphilis until all visible signs to him have disappeared, or even longer, and then cease, thinking that, as he feels as well as ever, there is no further need of taking medicine. Should such a man marry, it is all but certain that the fœtus would become tainted and perish in the early weeks of pregnancy. As a consequence the mother would become contaminated, and afterward each successive product of conception would perish likewise, unless a thorough course of treatment was taken by them both for two or three years at least. In all stages of gestation do these fœtuses perish. Should the virus be virulent, the ovum would be so poisoned from the very beginning that it would be quite unable to form any attachment to the uterine walls. If the virus is not so concentrated, it is possible for attachment to take place, but soon the vitality of the ovum exhausts itself and it is expelled. Again, the degree of syphilis may be so slight that the product of conception may go on to full term and a viable child be born, but so marked and scarred that it cannot be reared. So it is that this unfortunate and loathsome disease may be reckoned as one of the most frequent causes of intra-uterine death. The death and disaster which befell the army of Napoleon on its ill-fated march from Moscow are microscopically small compared to the fœtal wrecks which follow annually in the wake of syphilis.

Lead Poisoning.—Saturnine intoxication acts injuriously upon the fœtus without doubt. This occurs so

often in those who labor in lead works that it is altogether too frequent not to be causal. The death and expulsion of the fœtus from the wives of men so employed have long attracted the attention of the profession. Should such a child be born alive, its vitality may be so lowered that it does not long survive. Fathers suffering from saccharine diabetes or albuminuria are frequently unable to beget living children. It is likely that during the progress of these diseases the sexual energies fall into abeyance to a certain extent, and so lower the vitality of the spermatozoa that pregnancy cannot be continued to the full term of gestation.

(To be continued.)

A SIMPLE AND ACCURATE METHOD OF SUBSTITUTE INFANT FEEDING.*

BY HENRY DWIGHT CHAPIN, M. D.,
NEW YORK.

IN an article in the *New York Medical Journal* of November 4, 1899, I showed how completely cream rose on bottled milk, and that by using all the cream and different quantities of the remaining, or skim, milk weak creams, or top milks, containing almost any desired ratio between fat and proteids could be had from a quart bottle of milk as commonly delivered to families, and presented a dipper for removing these top milks from milk bottles.

In the *Journal of the American Medical Association* of July 14, 1900, I showed how good milk could be obtained, and gave assays of top milks taken from poor, medium, and rich whole milks, which showed by what small fractions the fat and proteids in the infant's food could be varied by simply varying the number of ounces removed from the top of the milk bottle and the number of times they were diluted. As this method of varying percentages is easy to apply and does away with all mathematical calculations, it has already been adopted by some of the leading pædiatricians and by many general practitioners.

It must not be supposed, however, that the problem of preparing a substitute for woman's milk consists of simply varying the percentages of fat, sugar, and proteids of cow's milk. The securing of good, clean milk and the choice of a diluent are factors equally important. It makes little difference for our purpose whether milk is rich or poor in solids, but it should be properly handled. Milk is rendered unfit for use by the growth of certain kinds of bacteria. The number of bacteria found in milk is an index of the care with which the milk has been handled. Lactic-acid bacteria, that are principally in the first three or four jets from each teat, cause souring; putrefactive bacteria come from stable

filth; germs of typhoid fever and other infectious diseases usually come from milkers or infected water used in washing utensils.

Starting with clean milk, there are two practical ways of preventing the growth of bacteria in the milk: 1. By keeping the milk cool. 2. By heating the milk to kill the bacteria. Superheating or sterilizing milk is undesirable, but is practised in Europe because ice is scarce. New York uses in a week about as much ice as Paris uses in a year or London in about five months. Properly handled and cooled, milk shipped from Illinois, New York, and New Jersey to the Paris exposition last summer was in better condition when it arrived than the daily milk supply of Paris. To get good milk, have the cows kept clean, and when milking throw away the first two or three jets from each teat. Have the milk of several cows cooled to at least below 60° F. and mixed immediately after milking; put the milk into clean bottles, and keep them cool with ice or by setting them in cold water.

When this milk is delivered to families, even morning milk will have a layer of cream in the neck of the bottle, usually about six ounces. Very little can be told about the richness of milk or cream by its appearance in the bottles. On October 5, 1899, I had a quart bottle of milk bought from each of nine large dealers in New York and Brooklyn. These were all carried to the laboratory of the Health Department and set in a row. There was not over a quarter of an inch difference in the depth of the cream in any of these bottles. All these milks were tested for fat and ranged from 3.1 per cent. to 4.6 per cent. of fat. Only two quarts were found to be of the same richness. The skim milk in one bottle contained as low as 0.32 per cent. of fat, and that in another as high as 1.78 per cent. of fat. The skim milk of all the others contained between 0.5 and 1.5 per cent. of fat.

The cream ran as low as 11.2 per cent. of fat and as high as 23 per cent. of fat. The cream in the neck of bottles is not uniformly rich in the different portions. Sometimes the cream at the mouth of the bottle is six times as rich as that near the skim milk.

There is no use in expecting accuracy in home modification of milk by mixing cream and milk, which vary so much, unless each lot can be tested, which is not practicable. All assumed or average compositions of milk or cream are useless and only confuse. Milk or cream standardized to the average composition is rarely fed to a baby. What can be procured must be used, and even in small towns different milkmen may supply several different grades of milk or cream, but the milk or cream of each dealer is usually fairly uniform in composition.
